CAST-IRON to COLE

CAST-IRON. It is said that cast-iron was first made in Sussex as early as the year 1350, but it was not until the end of the Tudor period that the practice of iron-founding was introduced into England from the continent of Europe where it had already been considerably developed. Although cast-iron and pig-iron have the same chemical composition, the expression cast-iron is generally applied to pig-iron which has been remelted in a crucible, or furnace, and cast into moulds.

Classification.—Cold- and hot-blast irons (*see* PIG-IRON) are divided, according to their content in phosphorus, into two main groups: (a) Hematite, and (b) Basic irons. The former contain only small percentages of this element, about .07%, while in the latter the phosphorus may reach as much as 3%. Each of these main groups is again subdivided into at least six grades, Nos. 1, 2, 3, foundry, forge and white irons. In passing along the series from "No. 1" to "white" the percentages of silicon and manganese gradually decrease, while those of combined carbon and sulphur increase. Hence it is possible, by mixing irons from different groups, to obtain cast-iron of almost any desired composition, due allowance being made for the changes which occur during remelting. Iron may be classified also according to (a) the method of manufacture; (b) the purpose for which it is intended; and (c) its composition. It was formerly graded by breaking the pig and examining the fracture, but this method has been largely superseded by chemical analysis.

(a) Method of Manufacture: (1) Coke Pig is smelted with coke; always with hot blast. (2) Charcoal Pig is smelted with charcoal, by hot or cold blast.

(b) Purpose for Which Intended: (3) Bessemer Pig. (4) Basic Open Hearth Pig. (5) Malleable Pig, for malleable cast-iron castings. (6) Foundry Pig. (7) Forge Pig is an inferior grade used for puddling and for some classes of foundry work.

(c) Chemical Composition: (8) Silicon Pig or High Silicon Pig. (9) Low Phosphorus Pig. (10) Special Low Phosphorus Pig. (11) Ferro-Alloys and Special Cast Irons (*e.g.*, ferro-manganese).

When pig-iron is melted under conditions which permit of the oxidation of the silicon, as in the cupola and reverberatory furnace, an iron which presents a greyish fracture when broken, and is quite soft and easy to machine, will, on continued remelting, ultimately become white and intensely hard. Conversely, by melting white iron with increasing quantities of siliceous pig-iron it is possible to convert the white into grey iron. These differences in appearance arise from changes in the condition of the carbon. Cast-iron contains upwards of 3.5% carbon, which in very grey iron is almost wholly in the graphitic state; this condition arises from the presence of large amounts of silicon, an element which has the property of decomposing carbide of iron (Fe_3C) into its constituents, iron and carbon. As the silicon is oxidized by remelting, more and more of the carbon combines with the iron, until ultimately, in white iron, carbon in the form of graphite is entirely absent. Manganese also is oxidized during remelting, while sulphur on the other hand is absorbed from the fuel.

Grades Commonly Used.—The following are examples of the grades in common use: for thin ornamental work, such as grates, stoves, hollow ware and other light castings, where in order to fill the mould great fluidity is required, a mixture of irons containing from 2.5% to 2.8% silicon and from 1.3% to 1.5% phosphorus is in common use; but in medium-sized castings and general work, where somewhat greater strength is required, iron containing a greater percentage of combined carbon and a reduced silicon content is necessary; and as strength rather than extreme fluidity is the main consideration, the phosphorus also may be reduced. For use in this connection, irons containing silicon from 2% to 2.25% and phosphorus from 1% to 1.3% are suitable. Where still greater strength is required, as in machinery castings, phosphorus and silicon are still further reduced, and a mixture of irons yielding an average content in silicon and phosphorus respectively of 1.15% to 1.2% and 0.4% to 0.6% is employed. In cases where castings have to resist wear, and have at the same time to machine with a highly polished surface, a very close grained iron is necessary, this condition being provided by an admixture of refined and cold-blast irons with an average silicon content of from 1% to 1.3%, and about 0.45% to 0.70% phosphorus. So far, only castings of the same physical properties throughout have been considered; for some classes of work, however, such as rolls used in the sheet metal industries and some types of car wheels, it is necessary to have an intensely hard surface and a soft interior in one and the same casting. This is obtained by taking advantage of the fact that given a suitable grade

of iron, it is possible by rapid cooling to retain the carbon in the outside portion of the casting in the combined condition. This process is known as "chill casting" and the parts of the mould where the metal is to be hardened are made of iron instead of sand, so that, when the molten metal comes in contact with them heat is so rapidly extracted from it that the separation of graphite is prevented, and the carbon retained in the combined condition; while towards the centre of the casting, where the rate of cooling is not so rapid, decomposition of the cementite can take place, and in consequence the iron in this region is quite soft. In this class of work the selection of the pig-iron is of the greatest importance, slight differences in composition having very marked influences on the depth to which the hardening effect penetrates. Iron for chill casting should be low in phosphorus, and silicon also should not be too high, or the carbon will not remain in combination. About 1·5% of silicon is probably best, but opinion is not unanimous on this point.

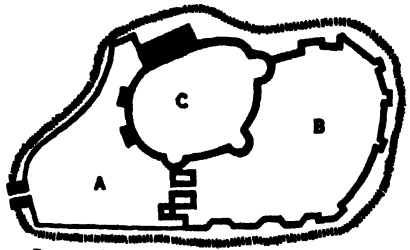
Malleable Cast-Iron.—Ordinary cast-iron is melted readily and easily cast into any desired shape, but it has the disadvantage that castings so made are relatively weak and brittle. It is possible, however, by making use of the facility with which carbide of iron can be split up into its constituents, to make castings which are stronger than ordinary cast-iron ones, and yet possess a considerable degree of ductility, almost approaching wrought-iron in this respect, though unlike forgings of the latter metal they cannot be welded, except by the "bronze rod" process, and at a temperature below the melting point of iron. Castings made in this way are called "malleable cast-iron castings," or shortly "malleable castings." The process has been in use for many years, having been described by Reaumur in 1722. For the production of castings by this method a refined hematite pig-iron is used containing from 2·5% to 3·0% carbon and from 0·5% to 1·0% silicon (the lower figure for large, and the higher one for small castings), and having as little as possible of sulphur, phosphorus, and manganese. Sulphur is supposed to promote the formation of blow-holes, but it has been found that 0·25% may be present without ill effect. Silicon and manganese prevent the castings being converted; while an excess of phosphorus causes brittleness in the finished casting. The castings, when removed from the moulds, are extremely brittle, on account of the nature of the pig-iron used, and when broken present a white fracture; they are packed in boxes containing red hematite ore and then annealed for a period of four or five days at a temperature of 800° to 900° C. After this treatment they present a grey fracture and can be readily dressed with a file or chisel; they will also admit of a considerable amount of deformation without fracture. The process described is the one followed in Europe. In America, where the decomposition of the carbide of iron, not the direct oxidation of the carbon, is regarded as the chief essential in the process of conversion, the annealing of the castings is carried out in a slightly different manner. They are packed in boxes containing sand or clay with or without admixture of oxide, and annealed at a temperature rather lower than that used in European practice, viz., 700° to 800° C. By either method a malleable casting is obtained, but the products of each when broken present a very different appearance and are designated "white heart" and "black heart" castings respectively, terms which explain themselves.

Since about 1850 the use of cast-iron for structural purposes has been gradually superseded by steel, but so many other applications have been found for it, that it is still in considerable demand, as it is the cheapest form of commercial iron. Its tensile strength, though considerably less than that of steel, is ample for many purposes, while in compression its strength is greater than that of any other known metal.

Hatfield *Cast-iron in the Light of Recent Research* (2nd ed. 1918); H. A. Schwartz *American Malleable Cast Iron;* Richard Moldenke *The Principles of Iron Founding.* (T. BA.)

CASTLE, a small self-contained fortress, usually of the middle ages, though the term is sometimes used of prehistoric earthworks (*e.g.*, Hollingbury castle, Maiden castle), and sometimes of citadels (*e.g.*, the castles of Badajoz and Burgos) and small detached *forts d'arrêt* in modern times. It is also often applied to the principal mansion of a prince or nobleman, and in France (as *château*) to any country seat. Under its twofold aspect of a fortress and a residence, the mediaeval castle is inseparably connected with the subjects of fortification (*see* FORTIFICATION AND SIEGECRAFT) and architecture. For an account of Roman and pre-Roman *castella* in Britain *see* BRITAIN.

Mediaeval Castles.—The word "castle" (*castel*) was introduced into English shortly before the Norman Conquest to denote a type of fortress, then new to the country, brought in by the Norman knights summoned by Edward the Confessor to defend Herefordshire against the inroads of the Welsh. The essential feature of this type was a circular mound of earth surrounded by a dry ditch and flattened at the top. Around the crest of its summit was placed a timber palisade. This moated mound was styled in French *motte* (latinized *mota*). It is clearly depicted in the Bayeux tapestry, and was then familiar on the mainland of western Europe. A description of this earlier castle is given in the life of John, bishop of Terouanne (*Acta Sanctorum,* quoted by G. T. Clark, *Mediaeval Military Architecture*):—"The rich and the noble of that region being much given to feuds and bloodshed, fortify themselves . . . and by these strongholds subdue their equals and oppress their inferiors. They heap up a mound as high as they are able, and dig round it as broad a ditch as they can. . . . Round the summit of the mound they construct a palisade of timber to act as a wall. . . . Inside the palisade they erect a house, or rather a citadel, which looks down on the whole of the neighbourhood." St. John, bishop of Terouanne, died in 1130, but this castle of Merchem may be taken as typical of the practice of the 11th century. In addition to the mound, the citadel of the fortress, there was often appended to it a bailey or basecourt (*see* BAILEY), and sometimes two, of semilunar or horseshoe shape, so that the mound stood *à cheval* on the line of the enceinte. The rapidity and ease with which it was possible to construct castles of this type made them characteristic of the Conquest period in England. In later days a stone wall replaced the timber palisade and produced what is known as the shell-keep, as in the castles of Berkeley, Alnwick and Windsor.



The Normans introduced also two other types of castle, the one where they found a natural rock stronghold which only needed adaptation, as at Clifford, Ludlow, the Peak and Exeter, to produce a citadel; the other a wholly distinct type, the high rectangular tower of masonry, of which the Tower of London is the best-known example. This type belongs rather to the more settled conditions of the 12th century when speed was not a necessity, and in the first half of which the fine extant keeps of Hedingham and Rochester were erected. These towers were originally surrounded by palisades, usually on earthen ramparts, which were replaced later by stone walls. The whole fortress thus formed was styled a castle, but sometimes more precisely "tower and castle," the former being the citadel, and the latter the walled enclosure, thus preserving the meaning of the Roman *castellum.* Reliance was placed by the engineers of that time simply on the inherent strength of the structure, the walls of which defied the battering-ram, and could only be undermined at the cost of much time and labour, while the narrow apertures were constructed to exclude arrows or flaming brands.

Influence of the Crusades.—At this stage the crusades, and the consequent opportunities afforded to western engineers of studying the solid fortresses of the Byzantine empire, revolutionized the art of castle-building, which henceforward follows recognized principles. Many castles were built in the Holy Land by the crusaders of the 12th century, and it has been shown (Oman, *Art of War: the Middle Ages,* p. 529), that the designers realized, first, that a second line of defences should be built within the main enceinte, and a third line or keep inside the second line; and secondly, that a wall must be flanked by projecting towers. From the Byzantine engineers, through the crusaders, we derive, therefore, the cardinal principle of the mutual defence of all the parts of a fortress. The *donjon* of western Europe was regarded as the fortress, the outer walls as accessory defences; in the East each envelope was a fortress in itself, and the keep became merely the

last refuge of the garrison. Indeed, the keep, in several crusader castles, is no more than a tower, larger than the rest, built into the enceinte and serving for its flanking defence, while the fortress was made strongest on the most exposed front. The idea of the flanking towers soon penetrated to Europe, and Alnwick castle (1140–50) shows the influence of the new system. The finest of all castles of the middle ages was Richard Coeur de Lion's Château Gaillard (1197) on the Seine near Les Andeleys. Here the innermost ward was protected by an elaborate system of strong defences, which included a *tête-de-pont* covering the Seine bridge. The castle stood upon high ground and consisted of three distinct enceintes or wards besides the keep, which was in this case merely a strong tower forming part of the innermost ward. Round instead of rectangular towers gradually became more usual, the finest examples of their employment as keeps being at Conisborough in England and at Coucy in France. Against the feeble siege artillery of the 13th century a well built fortress was almost proof, but the mines and the battering ram were more formidable, and it was realized that corners in the stonework of the fortress were more vulnerable than a uniform curved surface. Château Gaillard fell to Philip Augustus in 1204 after a strenuous defence, and the success of the assailants was largely due to the skilful employment of mines. An angle of the noble keep of Rochester was undermined and brought down by John in 1215.

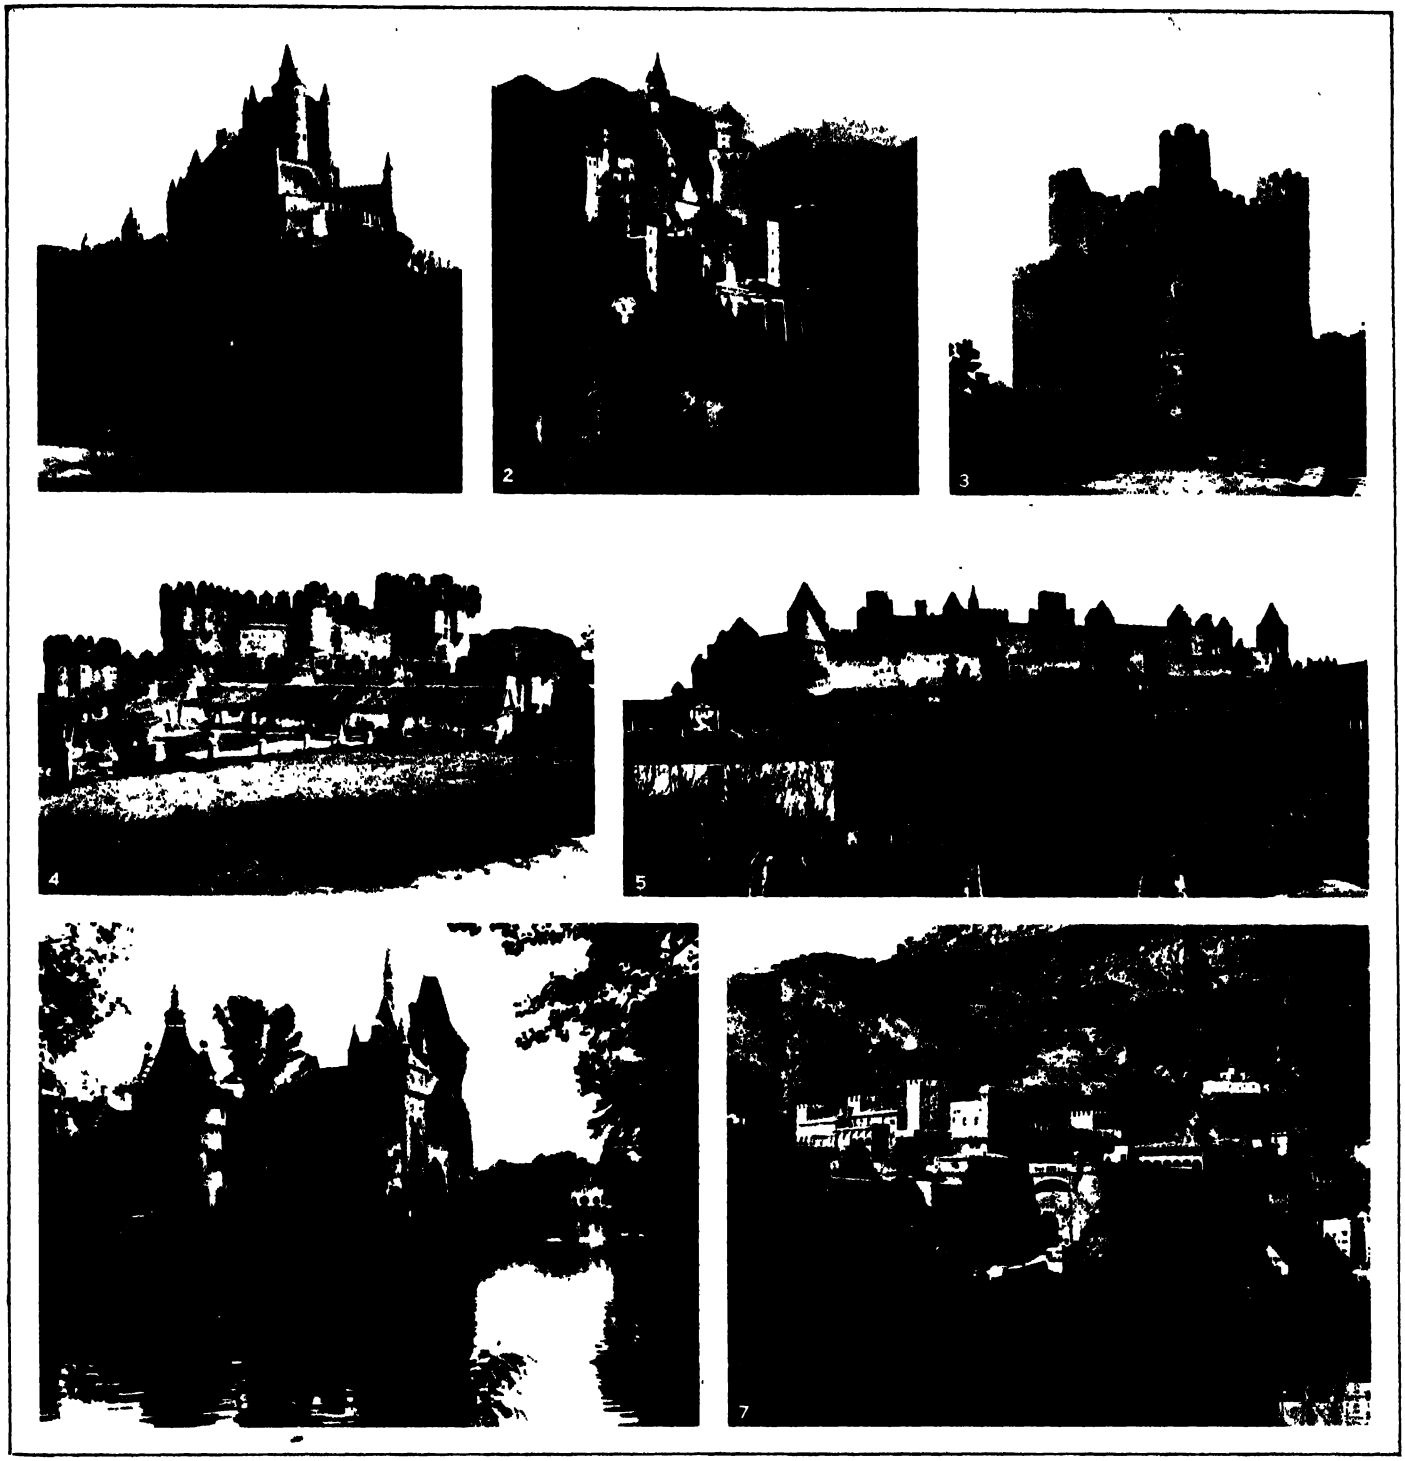
The Concentric Plan.—The next development was the extension of the principle of successive lines of defence to form what is called the "concentric" castle, in which each ward was placed wholly within another which enveloped it; places thus built on a flat site (*e.g.*, Caerphilly castle) became for the first time more formidable than strongholds perched upon hills such as Château Gaillard, where, although the more exposed parts possessed many successive lines of defence, at other points, for want of room, it was impossible to build more than one or, at most, two walls. In these cases, the fall of the inner ward by surprise, escalade or

regular siege (as was sometimes feasible), entailed the fall of the whole castle. The adoption of the concentric system precluded any such mischance, and thus, even though siege-engines improved during the 13th and 14th centuries, the defence maintained itself superior to attack during the latter middle ages. Its final fall was due to the introduction of gunpowder. "In the 14th century the change begins, in the 15th it is fully developed, in the 16th the feudal fastness has become an anachronism."

Decline of Baronial Fortifications.—The general adoption of cannon placed in the hands of the central power, a force which ruined the baronial fortifications. The possessors of cannon were usually private individuals of the middle classes, from whom the prince hired the *matériel* and the workmen. A typical case will be found in the history of Brandenburg and Prussia (Carlyle, *Frederick the Great*, bk. iii.; ch. i.), the castle of Friesack, held by an intractable feudal noble, Dietrich von Quitzow, being reduced in two days by the elector Frederick I. with "Heavy Peg" (*Faule Grete*) and other guns (Feb. 1414). In England, the earl of Warwick in 1464 reduced the strong fortress of Bamborough in a week, and in Germany, Franz von Sickingen's stronghold of Landstuhl, formerly impregnable on its heights, was ruined in one day by the artillery of Philip of Hesse (1523). Heavy artillery was used for such work, of course, and against lighter natures, some castles and even fortified country-houses managed to make a stout stand as late as the Great Rebellion in England.

The castle thus ceases to be the fortress of small and ill-governing local magnates, and its later history is merged in that of modern fortification. But an interesting transitional type between the mediaeval stronghold and the modern fortress is found in the coast castles erected by Henry VIII., especially those at Deal, Sandown and Walmer (*c.* 1540). Walmer castle is still the official residence of the lord warden of the Cinque Ports. Viollet-le-Duc, in his *Annals of a Fortress* (English trans.), gives a full and interesting account of the repeated renovations of the fortress on his imaginary site in the valley of the Doubs, the construction by Charles the Bold of artillery towers at the angles of the castle, the protection of the masonry by earthen outworks and boulevards and, in the 17th century, the final service of the mediaeval walls and towers as a pure *enceinte de sûreté*. Here and there we find old castles serving as *forts d'arrêt* or block-houses in mountain passes and in some few cases, as at Dover, they formed the nucleus of purely military places of arms, but normally the castle falls into ruins, becomes a peaceful mansion, or is merged in the fortifications of the town which has grown up around it. In the *Annals of a Fortress* the site of the feudal castle is occupied by the citadel of the walled town. The baronial "castle" assumes *pari passu* the form of a mansion, retaining indeed some capacity for defence, but in the end losing all military characteristics save a few which survived as ornaments. Examples of such castellated mansions are seen in Wingfield Manor, Derbyshire, and Hurstmonceaux, Sussex, created in the 15th century. Many older castles which survived were altered to serve as residences. (C. F. A.)

Castles in English History.—Such strongholds as existed in England at the time of the Norman Conquest seem to have offered but little resistance to William the Conqueror, who, in order effectually to guard against invasions from without as well as to awe his newly-acquired subjects, immediately began to erect castles all over the kingdom, and likewise to repair and augment the old ones. Besides, as he had parcelled out the lands of the English amongst his followers, they, to protect themselves from the resentment of the despoiled natives, built strongholds and castles on their estates, and these were multiplied so rapidly during the troubled reign of King Stephen that the "adulterine" (*i.e.*, unauthorized) castles are said by one writer to have amounted to 1,115.



In the first instance, when the interest of the king and of his barons was identical, the former had only retained in his hands the castles in the chief towns of the shires, which were entrusted to his sheriffs or constables. But the great feudal revolts under the Conqueror and his sons showed how formidable an obstacle to the rule of the king was the existence of such fortresses in private hands, while the people hated them from the first for the oppressions connected with their erection and maintenance. It was, therefore, the settled policy of the Crown to strengthen the royal castles and increase their number, while jealously keeping in check those of the barons. But in the struggle between Stephen and the empress Maud for the crown, which became largely a war of sieges, the royal power was relaxed and there was an outburst of castle-building by the barons. These in many cases acted as petty sovereigns, and such was their tyranny that the native chronicler describes the castles as "filled with devils and evil men." These excesses paved the way for the pacification at the close of the reign, when it was provided that all unauthorized castles constructed during its course should be destroyed. Henry II., in spite of his power, was warned by the great revolt against him that he must still rely on castles, and the massive keeps of Newcastle and of Dover date from this period.

Under his sons the importance of the chief castles was recognized as so great that the struggle for their control was in the forefront of every contest. When Richard made vast grants at his accession to his brother John, he was careful to reserve the possession of certain castles, and when John rose against the king's minister, Longchamp, in 1191, the custody of castles was the chief point of dispute throughout their negotiations, and Lincoln was besieged on the king's behalf, as were Tickhill, Windsor and Marlborough subsequently, while the siege of Nottingham had to be completed by Richard himself on his arrival. To John, in turn, as king, the fall of Château Gaillard meant the loss of Rouen and of Normandy with it, and when he endeavoured to repudiate the newly-granted Great Charter, his first step was to prepare the royal castles against attack and make them his centres of resistance. The barons, who had begun their revolt by besieging the castle of Northampton, now assailed that of Oxford and seized Rochester castle. The king recovered Rochester after a severe struggle and captured Tonbridge, but thenceforth there was a war of sieges between John with his mercenaries and Louis of France with his Frenchmen and the barons, which was especially notable for the great defence of Dover castle by Hubert de Burgh against Louis. On the final triumph of the royal cause, after John's death, at the battle of Lincoln, the general pacification was accompanied by a fresh issue of the Great Charter in the autumn of 1217, in which the precedent of Stephen's reign was followed and a special clause inserted that all "adulterine" castles, namely those which had been constructed or rebuilt since the breaking out of war between John and the barons, should be immediately destroyed. And special stress was laid on this in the writs addressed to the sheriffs.

In 1223 Hubert de Burgh, as regent, demanded the surrender to the Crown of all royal castles not in official custody, and though he succeeded in this, Falkes de Breauté, John's mercenary, burst into revolt next year, and it cost a great national effort and a siege of nearly two months to reduce Bedford castle, which he had held. In the Barons' War (*q.v.*) castles again asserted their importance. The Provisions of Oxford included a list of the chief royal castles and of their appointed castellans with the oath that they were to take; but the alien favourites refused to make way for them till they were forcibly ejected. When war broke out it was Rochester castle that successfully held Simon de Montfort at bay in 1264, and in Pevensey castle that the fugitives from the rout of Lewes were able to defy his power. Finally, after his fall at Evesham, it was in Kenilworth castle that the remnant of his followers made their last stand, holding out nearly five months against all the forces of the Crown, till their provisions failed them at the close of 1266.

Thus for two centuries after the Norman Conquest castles had proved of primary consequence in English political struggles, revolts and warfare. And, although, when the country was again torn by civil strife, their military importance was of small account, the crown's historic jealousy of private fortification was still seen in the need to obtain the king's licence to "crenellate" (*i.e.*, embattle) the country mansion.

TYPES OF FEUDAL CASTLES

1. Alcazar at Segovia, built by Henry IV. of Castile (1454–74). This castle, placed for defence on a high, narrow plateau, served not only as the king's residence but also as the stronghold of the city walls. It is characteristic of the castle form which grew out of the combined military and residential requirements of the feudal period
2. The Bavarian royal castle of Neuschwanstein, although modern, accurately represents the type of castle building developed in the hills of Germany in the middle ages. It is a product of the German Romantic Movement, built for Ludwig II. to rival the castle of Wartburg, whose design it closely follows
3. Rochester castle, Kent, the great square keep, 120 feet high, all that remains of the original castle, which was probably built before 1126, by William de Corbeil, archbishop of Canterbury. (It belongs to the type of square Norman castle keep, illustrated also by the Tower of London)
4. Castella Coca, Spain, built soon after 1473. Like Alcazar at Segovia, it is one of a chain of fortifications built by the kingdom of Castile during the reconquest of Spain from the Moors. Its warm red brick walls and projecting turrets belong to the style called *Mudejar*, which was developed by Moorish workmen under Christian supervision. The battlements are of the Moorish type
5. Walls of the citadel of Carcassonne, dating from the 13th and early 14th centuries, as restored under the direction of Viollet-le-Duc in the middle of the 19th century. The restoration gives an idea of the original appearance of a great mediaeval castle, of which the high, unbroken, battlemented walls and projection towers, either square with battlements or round with conical roofs, are characteristic features
6. Castle of Vajda Hunyadi in Hungary, showing characteristics similar to castles in western Europe. The projection of the upper part of the towers—machicolation—enabled defenders to discharge missiles directly upon the attackers below. The buildings shown in this picture date chiefly from about 1400 with parts of the residence portion of a later date
7. Palace of the Prince of Monaco. 17th century castle as restored

TWO CASTLES OF GREAT BRITAIN

Windsor castle, a fortified spot since the early 11th century and a royal residence from the time of William the Conqueror. The round mound and ditch encircling the present round tower go back to the earliest building. In its present form, however, the castle dates largely from the time of Henry III., who built the first masonry structure (c. 1270), and Edward III., who almost entirely reconstructed it in 1344, as a meeting place for the Knights of the Garter. From that time on it has been continuously added to and improved—St. George's chapel, dating from 1473 to 1507; the Albert Memorial chapel, largely from 1501–03, (although the interior was much altered by Sir Gilbert Scott under Queen Victoria as a memorial to the prince consort) and the state apartments and residence quarters in the upper ward (to the right) from a reconstruction under George IV. and Queen Victoria, from designs by Sir Jeffrey Wyatville, who also increased the height of the old keep—the round tower near the centre. The oldest part of the existing castle is the round bell tower at the extreme left, with its high roof of French type, which dates from the time of Henry III. The greater part of the more recent construction having been built on foundations of older work, the whole presents an unusually vivid picture of what mediaeval castles of the largest type must have been in their prime

2. Carnarvon castle, Wales. Much smaller than Windsor, this also retains its ancient appearance. It was begun in 1283–84 by Edward I., from designs by his famous castle architect, Henry de Elreton, and was one of a chain of castles, including Conway and Beaumaris, intended for the pacification of the Welsh. Carnarvon was not completed until the reign of Edward II. Originally, a wall in the centre of the enclosed area divided it into two wards. The towers are of the British polygonal type. In France, at the time, round towers had become common. Despite the destruction of the interior residential buildings, Carnarvon castle is among the best preserved of those in the British Isles

CASTLEBAR, urban district and county town of Co. Mayo, Ireland, on the river and near the lough of same name. Pop. (1951) 5,288. The castle belonged to the De Burgh family but the town was founded in the reign of James I and received a charter in 1613. In 1641 the castle fell to the royalists. The town was held for a short period in 1798 by the French. Four miles northeast is a round tower 70 ft. high and 57 ft. in circumference. Trade is in linen goods and agricultural produce.

CASTLECONNELL, a village of Co. Limerick, Ireland, on the left bank of the Shannon, 18 mi. S.E. of Limerick on the Great Southern railway. There are remains of a castle from which the town took its name, which was the seat of the kings of Thomond. It was destroyed in 1690. Castleconnell is a centre for the salmon fishing of the lower Shannon. Pop. (1951) 244.

CASTLE DONINGTON, a town of northwest Leicestershire, Eng., 9¾ mi. S.E. of Derby by road. The population of the rural district in 1951 was 9,273 and of the parish (estimated) 2,967. The town lies on the flank of a hill overlooking the Trent valley. Hosiery, baskets and lace are the chief industries. Little remains of the castle, demolished by King John but rebuilt in 1278. The church of St. Edward is of Early English and later date. Donington hall is a castellated mansion standing in a park. The estate was once in the possession of Thomas Plantagenet, who sold it in 1594 to the earl of Huntingdon. In 1789 the then earl bequeathed it to the earl of Moira, who erected the present house in 1793.

CASTLE-DOUGLAS, a small burgh, Kirkcudbrightshire, Scot. Pop. (1951) 3,322. It lies at the north end of Carlingwark loch, about 8 mi. S.W. of Dumfries. It is the chief business centre of east Galloway and its sheep and cattle sales are the largest in the southwest of Scotland. Until 1765 it was only a village under the name of Causewayend, but the discovery of marl in the lake brought it prosperity and it was bought in 1792 by Sir William Douglas and renamed after him. On one of the islets in the loch is a crannog, or ancient lake dwelling. Threave castle, the Douglas stronghold (1369–1455) on an island in the Dee, was given to the National trust in 1948.

CASTLEFORD, an urban district in the West Riding of Yorkshire, Eng., 10 mi. S.E. of Leeds by road. Pop. (1951) 43,116. The district was considerably extended in 1938 and covers 6.8 sq.mi. There are collieries and large glass bottle and chemical works. It stands where Ermine street crosses the Aire river near its junction with the Calder and on the site of the Roman Legeolium. In 948 the name appeared as Ceasterford.

CASTLE GATE, a town in Carbon Co., Utah; 6,120 ft. above sea level; pop. (1950) 701. The name was taken from that of the gatelike passage in the canyon of Price river 1 mi. above the town. There projecting pinnacles of gray sandstone, 650–700 ft. high, close in on the valley, leaving only a narrow passage resembling a gateway in the walls of a ruined castle. The town is the home of one of the largest producing coal mines in the Book Cliffs field, originally opened by the Pleasant Valley Fuel Co. in 1888 and bought by Henry J. Kaiser interests in 1950.

CASTLE-GUARD, an arrangement under the feudal system, by which the duty of finding knights to guard royal castles was imposed on certain baronies and divided among their knights' fees. The greater barons provided for the guard of their castles by exacting a similar duty from their knights. In both cases the obligation was commuted very early for a fixed money payment, which, as "castle-guard rent," lasted down to modern times.

See J. H. Round, "Castle-Guard," in *Archaeological Journal*, vol. lix, and "Castleward and Coinage," in *The Commune of London* (1899); S. Painter, in *American Historical Review*, vol. xi, pp. 450–459 (1935); F. M. Stenton, *The First Century of English Feudalism*, pp. 190–215 (Oxford, 1932).

CASTLEMAINE, ROGER PALMER, EARL OF (1634–1705), first husband of the duchess of Cleveland (*see* CLEVELAND, BARBARA VILLIERS, DUCHESS OF), English diplomatist and author. He was an ardent Roman Catholic, who defended his coreligionists in several publications. He wrote on account in French of the war against Holland (1665–67) in which he had served. Denounced by Titus Oates as a Jesuit he was tried and acquitted, later serving James II as ambassador to Pope Innocent XI. After James II's flight, his Jacobite sympathies caused him to be suspected by the government, and his time was mainly spent either in prison or in exile.

Castlemaine died at Oswestry on July 21, 1705.

CASTLEMAINE, a town 70 mi. N.W. of Melbourne, Victoria, Australia. Pop. (1947) 5,809. Castlemaine's gold mines were among the first discovered in the colony. Slate and flagstone are quarried in the district, which is also an important wine and fruit-producing area. It is near the centre of the chief sheep belt of Australia.

CASTLE PINCKNEY NATIONAL MONUMENT, a tract of three and one-half acres in South Carolina, U.S., set apart in 1924 as a government reservation. It is the site of a fort which was erected in 1810 and had previously been occupied by a revolutionary fort.

CASTLEREAGH, VISCOUNT: *see* LONDONDERRY, ROBERT STEWART, 2ND MARQUESS OF.

CASTLE RISING, a small village of Norfolk, Eng., 4½ mi. N.E. of King's Lynn. The fine Norman keep stands within a 12-ac. enclosure, formed by artificial ramparts of earth, and a dike, which is crossed by an ancient bridge. The keep is square and massive, and the Norman carving, especially over the entrance, is very rich. The foundations of a small chapel were discovered outside the castle. The village of Castle Rising is the remnant of a town of no little importance. It is mentioned in Domesday Book and was later granted to William de Albini, whose son built the castle. It passed to Isabella, queen of Edward II, in 1332 but was exchanged for Brest castle by Richard II. It reverted to the crown in the 14th century and so remained until Henry VIII exchanged it for other lands with Thomas Howard, duke of Norfolk. A mayor is first mentioned in 1343 and a borough existed in the 15th century. A survey of 1589–90 declared that Castle Rising was an ancient borough by prescription. Castle Rising became a parliamentary borough in 1558, but was disfranchised in 1832, although a mayor was elected for special purposes until 1883. Its fairs and markets were formerly important. The church of St. Laurence is late Norman, with rich ornamentation; it shows traces of considerable alteration in the Early English period. The Bede house, founded in 1614 by Henry Howard, earl of Northampton, is an almshouse for old women. Its inhabitants still on occasion wear the high hats and red cloaks of Stuart times.

CASTLETON, a village of north Derbyshire, Eng., 17 mi. W. of Sheffield by road. Population (1949) 684. It lies about 600 ft. above sea level and is closely surrounded by limestone hills rising to heights of 1,400 to 1,700 ft. It is visited for its caves and mines—especially the Peak cavern, Treak Cliff cavern, the Speedwell mine and the Blue John mine and for Peveril castle, now a ruin, perched on a cliff above the village. Penetrating this cliff is the Peak cavern, which from the 16th century has served as a workshop, rent-free, to families making rope and twine. The strongly placed castle owes its fame to its site and to Sir Walter Scott's novel *Peveril of the Peak;* the fabric has been well repaired by the ministry of works. Before the Conquest the site was held by Gernebern and Hundinc, and early earthworks can still be traced. It was granted by William the Conqueror to William Peverel, who built the castle. In 1216 William Ferrers, earl of Derby, took it from the rebellious barons and was made governor by Henry III, who in 1223 granted a charter for a weekly market. In 1328 the castle was given to John of

Gaunt on his marriage with Blanche of Lancaster and thus became part of the duchy of Lancaster. Often used as a prison, it was almost impregnable in its day.

The church of St. Edmund at Castleton has a Norman chancel arch, old-fashioned box pews and a valuable collection of old books. The Speedwell mine, ¾ mi. W. of the village, offers the remarkable experience of a boat trip along a subterranean canal whose waters reappear in the village stream. Treak Cliff cavern has fine stalactitic formations, as also has the Blue John mine, the source of a beautiful fluorspar known as Blue John.

CASTLETOWN, the ancient capital of the Isle of Man (in Manx called *Balla Cashtal*), 8½ mi. S.W. of Douglas. Pop. (1951) 1,742. Area 2 sq.mi. A small tidal harbour is formed by the outflow of the Silverburn into Castletown bay. Castle Rushen, in the centre of the town, is said to have been founded in 947–960. The present building is essentially Norman, largely rebuilt in the 14th century and added onto in the 16th. Until the 18th century it was the residence of the lords of Man. The massive keep is square and is surrounded by an outer wall with towers and a moat. The council chamber and courthouse were built in 1644. Near the castle is the old House of Keys, where the Manx parliament met until the removal of the seat of government to Douglas in 1862. King William's college (endowed in 1668, founded in its present form in 1833) a mile N.E. of Castletown, is the principal school in the island. At Derbyhaven, adjoining Castletown, is the Ronaldsway airport.

CASTOR AND POLLUX, in Greek and Roman mythology the twin sons of Leda, and brothers of Helen and Clytaemnestra. They were also known as *Dioscuri* (Gr. "lads of Zeus"), for, according to later tradition, they were the children of Zeus and Leda, whose love the god had won under the form of a swan. In some versions Leda is represented as having brought forth two eggs, from one of which Castor and Pollux were born, from the other Helen. According to another account, Zeus was the father of Pollux and Helen, Tyndareus (king of Sparta) of Castor and Clytaemnestra. In Homer they are said to have been the children of Tyndareus and Leda, and Helen is said to have been the daughter of Leda by Zeus. The Dioscuri were specially reverenced among people of Dorian race, and were said to have reigned at Sparta, where also they were buried. They were the friends of sailors, appearing in the shape of St. Elmo's fire during storms. Later, they were confounded with the Cabeiri (*q.v.*).

CASTOREUM, an oily viscid gland secretion contained in two pairs of membranous sacs between the anus and external genitals of both the male and the female Russian and American beaver; known also as beaver musk. After drying, it comes into commerce as more or less solid masses, of brown colour and a strong, rather disagreeable odour, due to the presence of about 2% of an essential oil, in addition to which a number of odourless organic and inorganic substances have been isolated. It was formerly used medicinally as a stimulant in hysterical affections, but at present serves almost exclusively for blending perfumes, in the same way as musk and civet, usually in the form of an alcoholic extract.

CASTOR OIL, the fixed oil obtained from the seeds of the castor-oil plant or Palma Christi, *Ricinus communis*, family Euphorbiaceae. The plant is a native of tropical Africa, but is cultivated in most tropical and warmer temperate countries. Besides oil the seeds contain a powerful toxic substance (ricin) one of the phytotoxins to which an antiserum has been produced by immunological methods.

Much oil of excellent quality is obtained from India, Italy and California, U.S. The oil is obtained from the seeds by expression and decoction. One hundred pounds of good seeds may yield about five gallons of pure oil.

Castor oil is a viscid liquid, almost colourless when pure, with a slight odour, and a mild yet nauseous taste. Its specific gravity is 0.96 and it dissolves freely in alcohol, ether and glacial acetic acid. It contains palmitic and several other fatty acids, but the chief is ricinoleic acid which occurs in combination with glycerin. The ricinoleic acid is liberated by the gastric juices, and acts as a mild irritant to the gut. The dose is from one-half to one ounce. It acts in about five hours, increasing peristaltic and segmenting movements in the small intestine and allaying the normal antiperistalsis in the large bowel. It is useful for children and the aged, but must not be employed in cases of chronic constipation, which it only aggravates, while relieving the symptoms. It is also used as a lubricant especially in aeroplane motors.

CASTRATO, an adult male soprano who has been operated on in his youth to prevent his voice from changing in the ordinary way to the normal masculine pitch. In former days such singers were very numerous and included some of the most famous in the whole history of the art, such as Caffarelli, Velluti, Senesino and Farinelli, but thanks to improved public opinion the abominable practice to which they owed their existence has now been entirely abandoned. Evirati was another name for singers of this class.

CASTREN, MATTHIAS ALEXANDER (1813–1853), Finnish ethnologist and philologist, was born at Tervola, Kemi, Finland, on Dec. 2, 1813. In 1838 he joined a medical fellow-student, Dr. Ehrström, in a journey through Lapland. In the following year he travelled in Russian Karelia; and in 1841 he undertook, in company with Dr. Elias Lönnrot, a third journey, which extended as far as Obdorsk, and occupied three years. On his return he published his *Elementa grammatices Syrjaenae* and *Elementa grammatices Tscheremissae* (1844). He then undertook an exploration of the whole government of Siberia, which resulted in a vast addition to previous knowledge, but seriously affected his health. The first-fruits of his collections were published as *Versuch einer ostjakischen Sprachlehre* (St. Petersburg, 1849). In 1850 he published a treatise *De affixis personalibus linguarum Altaicarum,* and was appointed to the new chair of Finnish language and literature at Helsingfors, next year becoming chancellor of the university. He was engaged on a Samoyedic grammar when he died on May 7, 1853.

Five volumes of his collected works appeared from 1852 to 1858, containing respectively—(1) *Reseminnen från åren 1845–44;* (2) *Reseberättelser och bref åren 1845–49;* (3) *Föreläsningar i Finsk mythologi* (Germ. trans. by A. Schiefner, 1853); (4) *Ethnologiska föreläsningar öfver Altaiska folken;* and (5) *Smärre afhandlingar och akademiska dissertationer.*

CASTRENSIS, PAULUS, an Italian jurist of the 14th century. He studied under Baldus at Perugia, and was a fellow-pupil with Cardinal Zabarella. He was admitted to the degree of doctor of civil law in the University of Avignon, but it is uncertain when he first undertook the duties of a professor. A tradition, which has been handed down by Panzirolus, represents him as having taught law for a period of 57 years. He was professor at Vienna in 1390, at Avignon in 1394, and at Padua in 1429; and, at different periods, at Florence, at Bologna and at Perugia. He was for some time the vicar general of Cardinal Zabarella at Florence, and his eminence as a teacher of canon law may be inferred from the language of one of his pupils, who styles him "famosissimus juris utriusque monarca." His most complete treatise is his readings on the *Digest,* and it appears from a passage in his readings on the *Digestum Vetus* that he delivered them at a time when he had been actively engaged for 45 years as a teacher of civil law. His death is generally assigned to 1436, but it appears from an entry in a ms. of the *Digestum Vetus,* which is extant at Munich, made by the hand of one of his pupils who styles him "praeceptor meus," that he died on July 20, 1441.

CASTRES, a town of southwestern France, capital of an arrondissement in the department of Tarn, 29 mi. S.S.E. of Albi. Pop. (1946) 30,781. The busiest town of its department, it has been a cloth-working centre since the 14th century. It lies on both banks of the Agout, which is fringed by old houses with projecting upper storeys.

Castres grew up round a Benedictine abbey, probably founded in the 7th century. It was a place of considerable importance as early as the 12th century, and ranked as the second town of the Albigenses. During the Albigensian crusade it surrendered to Simon de Montfort: in 1356 it was raised to a countship by King John of France, and was united to the crown by Francis I in 1519. In the wars of the late 16th century the inhabitants sided with the Protestant party, fortified the town, and established an independent republic. They were brought to terms, however, by

Louis XIII, and forced to dismantle their fortifications; and the town was made the seat of the *chambre de l'édit*, for the investigation of the affairs of the Protestants, transferred (in 1679) to Castelnaudary. The bishopric of Castres, established by Pope John XXII in 1317, was abolished at the Revolution. The church and former cathedral of St. Benoît dates only from the 17th and 18th centuries. The *hôtel de ville*, which contains a museum with some fine paintings by Goya, occupies the former bishop's palace, designed by Jules Mansart in the 17th century; the Romanesque tower beside it is the only survival of the abbey. Of several old mansions the Renaissance hôtel de Nayrac is the most interesting. Castres has a subprefecture, tribunals of first instance and of commerce, a board of trade arbitrators and a chamber of commerce. Industries include, in addition to clothmaking, metalworking, tanning, turnery and the making of wooden shoes and furniture.

CASTRO, INEZ DE (d. 1355), mistress, and perhaps wife, of Peter I (Pedro), king of Portugal, called *Collo de Garza, i.e.*, "Heron's Neck," was born in Spanish Galicia, in the earlier years of the 14th century, daughter of Don Pedro Fernandez de Castro, and Dona Aldonça Soares de Villadares, a noble Portuguese lady. Educated at the semioriental provincial court of Juan Manuel, duke of Peñafiel, Inez grew up with Costança, the duke's daughter by a descendant of the royal house of Aragon, and her own cousin, who married in 1341 the infante Dom Pedro, son of Alphonso the Proud, king of Portugal. The young infanta and her cousin left Peñafiel and went to reside at Lisbon or at Coimbra, where Dom Pedro conceived that luckless passion for Inez which has immortalized them. Pedro's connection *par amours* with Inez would of itself have aroused no opposition. He might even have married her after the death of his wife in childbirth in 1345. According to his own assurance he did marry her in 1354. But by that time the rising power of the Castro family had created hatred among their rivals, both in Spain and Portugal. Alvaro Gonzales, Pedro Coelho and Diogo Lopes Pacheco persuaded the king, Alphonso, that his throne was in danger from an alliance between his son and the Castros, and urged the king to remove the danger by having Inez murdered. The old king went in secret to the palace at Coimbra, where Inez and the infante resided, accompanied by his three familiars, and by others who agreed with them. The beauty and tears of Inez disarmed his resolution, and he turned to leave her; but the men about him had gone too far to recede. Inez was stabbed to death and was buried immediately in the church of Santa Clara.

The infante had to be appeased by the concession of a large share in the government. The three murderers of Inez took refuge in Castile. In 1357, however, Alphonso died, and the infante was crowned king of Portugal. Peter the Cruel, his nephew, surrendered the murderers. Diogo Lopes escaped, but Coelho and Gonzales were executed, with horrible tortures, in the king's presence

The story, not authenticated, of the exhumation and coronation of the corpse of Inez has often been told. It is said that to the dead body, crowned and robed in royal raiment and enthroned beside the king, the assembled nobles of Portugal paid homage as to their queen, swearing fealty on the withered hand of the corpse.

Inez was buried at Alcobaça, with extraordinary magnificence, in a tomb of white marble, surmounted by her crowned statue, destroyed by the French soldiery in 1810. From the brother of Inez, Alvaro Perez de Castro, the house of Portugal directly descended.

CASTRO, JOÃO DE (1500–1548), called by Camoens *Castro Forte*, viceroy of the Portuguese Indies, the son of Alvaro de Castro, governor of Lisbon, served in north Africa between 1518 and 1538. In 1535 he accompanied the infante Dom Luis, son of Emanuel I, to the siege of Tunis. Returning to Lisbon, he received from the king the small commandership of São Pablo de Salvaterra. Soon after this he went with his uncle Garcia de Noronha to the Indies. On arrival at Goa he volunteered for the relief of Diu. Returning to Europe, he was given command in 1543 of a fleet to clear the European seas of pirates. In 1545 he was sent to the Indies with six sail. He defeated Mahmud king of Gujarat and the Adil Khan and relieved Diu, losing one of his sons in the battle. He then captured Broach, subdued Malacca, and in 1547 was appointed viceroy by João III. He died at Ormuz, in the arms of his friend St. Francis Xavier, on June 6, 1548. He was buried at Goa, and afterward taken home and buried in the convent of Bemfica.

BIBLIOGRAPHY.—Jacinto Freire de Andrade, *Vida de D. João de Castro* (1651), Eng. trans. by Sir Peter Wyche (1664); Diogo de Couto, *Decadas da Asia*, vi. The *Roteiros* or logbooks of Castro's voyages in the East (Lisbon, 1833, 1843 and 1872) are of great interest.

CASTROGIOVANNI (ENNA), a town and episcopal see (Arab., *Kasr-Yani*, corruption of *Castrum Ennae*), capital of the province of Enna, Sicily, 95 mi. by rail southeast of Palermo and 56 mi. west of Catania. It is situated in a strong strategic position, almost in the centre of the island, commanding a magnificent view of the interior. Pop. (1936) 21,261 (town); 23,817 (commune). Enna was one of the Sicel cities and the statement that it was colonized by Syracuse in 664 B.C. is improbable. It appears in history under Dionysius I of Syracuse, who after unsuccessful attempts finally acquired possession by treachery about 397 B.C. In 134–132 it was the headquarters of the slave revolt and was reduced only by treachery. Cicero speaks of it as a place of some importance, but in imperial times it seems to have been of little account. It was only by betrayal that the Saracens were able to take it in 859. In 1087 it fell into the hands of the Normans; and surviving fortifications are entirely mediaeval. The cathedral (1307) and a castle built by Frederick II of Aragon about 1300 are outstanding points of interest. There are no remains of the famous temple of Demeter, from which Verres, as Cicero tells us, removed the bronze statue of the goddess.

The lake of Pergusa where Persephone was carried off by Hades (Pluto, Dis), lies 4 mi. to the south.

Enna became a summer resort and established trade in sulphur and rock salt. It was the scene of heavy fighting in World War II.

CASTRO URDIALES, a port of northern Spain, province of Santander, on the Bay of Biscay and terminus of a branch railway connected with the Bilbao-Santander line. Pop. (1940) 6,181 (mun., 11,963).

Castro Urdiales is a modern town although its castle and parish church, on the rocky peninsula which protects the tiny bay, date from the middle ages when it was an important fishing port. Destroyed by the French in 1813, it was quickly rebuilt and increased rapidly in population and prosperity with the development of neighbouring iron mines and of railway communication, which took place after 1879. The port is naturally sheltered but an artificial harbour has been constructed. Iron ore is by far the greatest export, but fish, especially sardines in oil, and *chacolí* wine are also important.

CASTRO Y BELLVIS, GUILLÉN DE (1569–1631), Spanish dramatist, was a Valencian by birth, and early enjoyed a reputation as a man of letters. In 1591 he became a member of a local literary academy called the *Nocturnos*. At one time he was a captain of the coast guard, at another the protégé of Benavente, viceroy of Naples, who appointed him governor of Scigliano, near Naples. Castro was patronized by Osuna and Olivares, and was nominated a knight of the order of Santiago in 1623. He settled at Madrid in 1626, and died there on July 28, 1631, in such poverty that his funeral expenses were defrayed by charity. He probably made the acquaintance of Lope de Vega at the festivals (1620–22) held to commemorate the beatification and canonization of St. Isidore, the patron saint of Madrid. On the latter occasion Castro's *octavas* were awarded the first prize. Lope de Vega dedicated to him a celebrated play entitled *Las Almenas de Toro* (1619), and when Castro's *Comedias* were published in 1618–21 he dedicated the first volume to Lope de Vega's daughter. The drama that has made Castro's reputation is *Las Mocedades del Cid* (1599?), to the first part of which Corneille was largely indebted

for the materials of his tragedy. The two parts of this play, like all those by Castro, have the genuine ring of the old romances; and, from their intense nationality, no less than for their primitive poetry and flowing versification, were among the most popular pieces of their day.

Castro's *Fuerza de la costumbre* is the source of *Love's Care*, a play ascribed to Fletcher. He is also the reputed author of *El Prodigio de los Montes*, from which Calderón derived *El Mágico prodigioso*.

His *Obras* were edited by E. J. Martínez (Madrid, 1925).

CASTRUCCIO CASTRACANI DEGLI ANTELMINELLI (1281–1328), duke of Lucca, born March 29, 1281, at Castruccio, near Lucca, was a noted *condottiere* and Ghibelline. He was exiled at an early age with his parents and others of their faction by the Guelphs, who were then in power. He served under Philip IV of France in Flanders, then with the Visconti in Lombardy, and in 1313 under the Ghibelline chief, Uguccione della Faggiuola, lord of Pisa, in central Italy. He assisted Uguccione in many enterprises, including the capture of Lucca (1314) and the victory over the Florentines at Montecatini (1315). An insurrection of the Lucchese led to the expulsion of Uguccione and his party, and Castruccio regained his freedom and position, and the Ghibelline triumph was assured. In 1316 he was elected lord of Lucca, and spent many years in incessant warfare against the Florentines.

He was at first the faithful adviser and stanch supporter of Frederick of Austria, who made him imperial vicar of Lucca in 1320. After the battle of Mühldorf he switched his allegiance to the emperor Louis the Bavarian, whom he served for several years. He defeated the Florentines at Altopascio in 1325, the year in which he was created duke of Lucca, Pistoja, Volterra and Luni by the emperor Louis the Bavarian. In 1327 he captured Pisa, of which he was made imperial vicar. But, subsequently, his relations with Louis seem to have grown less friendly and he was afterward excommunicated by the papal legate in the interests of the Guelphs. He died Sept. 3, 1328.

BIBLIOGRAPHY.—Niccolò Machiavelli's *Life of Castruccio* is a mere romance; it was translated into French, with notes, by Dreux de Radier in 1753. *See* F. Winkler, *Castruccio, Herzog von Lucca* (Berlin, 1897); Gino Capponi, *Storia di Firenze* and G. Sforza, *Castruccio Castracani degli Antelminelli in Lunigiana* (Modena, 1891); and S. de Sismondi *Histoire des républiques italiennes* (Brussels, 1838).

CASTRUM MINERVAE, an ancient town of the Sallentini in Calabria, 10 mi. south of Hydruntum (mod. Otranto), with an ancient temple of Minerva, said to have been founded by Idomeneus, who formed the tribe of the Sallentini from a mixture of Cretans, Illyrians and Italian Locrians. It is also said to have been the place where Aeneas first landed in Italy, the port of which he named *Portus Veneris*.

CAST STEEL: *see* CRUCIBLE CAST STEEL.

CASUAL LABOUR is a term used to denote discontinuous or irregular employment or, as a collective, the workers subject to such employment.

GREAT BRITAIN

Building.—The term casual labour is sometimes used to describe the employment conditions in such trades as building, which are frequently subject to large seasonal fluctuations. These fluctuations may be due directly to the climate: statistical inquiry has shown in various European countries a distinct correlation between the seasonal decline in employment in the industry during the winter months and the prevailing temperature during these months. Technological advances, however, considerably extended the possibilities of building construction in cold weather; and while in some respects the cost of winter building exceeds that of summer work, this may be offset by the benefits of eliminating seasonal fluctuations. Nevertheless, in the United Kingdom before 1939 there was a widespread reluctance on the part of prospective occupants to take a new house built at any other time than between April and September. Naturally this attitude disappeared in consequence of the housing shortage following World War II. Elsewhere leasing dates affect the period over which building tends to be spread. The matter is further discussed in the International Labour office report on *Seasonal Unemployment in the Construction Industry* (1951).

Port Labour.—The term casual worker is, however, more usually applied to the man whose employment normally, and not only periodically, consists of a succession of jobs of short duration, whose contract of engagement is by the day and even by the hour, and who, from the method by which he is engaged, may be uncertain in the morning whether work will be available in the afternoon. He was typified, particularly during the latter part of the 19th and the earlier part of the 20th centuries, by the casual labourer at the docks. It was in the dock industry and the ancillary transport trades that casualization was most extensive; it was here that the phenomenon was investigated at greatest length, and here that the biggest efforts toward decasualization were made.

The conditions governing labour in the London docks during the early years of the 20th century were succinctly described by William Henry Beveridge (afterward Lord Beveridge) in *Unemployment* (London, 1908). They may be taken as broadly applicable to the other large dock areas of Great Britain. The fundamental condition leading to the existence of casual labour in the docks was that the demand for labour was distributed among a multitude of different employers with little fluidity or co-operation between them. Two important features were the great irregularity of the arrival and departure of cargoes and the small extent to which machinery had at that time and even later been able to displace manual work. As a consequence of the irregularity of cargoes there were considerable daily or weekly variations in the amount of work to be done at any one centre of waterside employment. As a consequence of the dependence on manual labour the effects of this varying demand tended to be thrown mainly upon the labourers, whom, beyond certain limits, it was uneconomic to employ regularly, and who were taken on and put off at short notice as they were wanted or were not needed. Every distinct centre of waterside employment required for its smooth working to have immediately available a larger number of men than it could employ regularly or even adequately. From this it followed that each separate employer, in order to be able to call upon sufficient labour to satisfy his peak demand, tended to keep available a separate pool of potential labour; the aggregate of all these separate pools was much larger than would have been the case had there been complete co-operation and complete fluidity between the various centres of employment.

Each employer engaged his men as and where he could get them. What generally happened was that a number of men would assemble in a stated place at a stated time, and the employer's foreman would select workers from them, thus collecting a labour force sufficient to meet his firm's requirements for the next few hours. The formation of these separate pools of labour probably came about largely unconsciously. Men tended to return to a centre where they had previously been successful in getting work, and where they hoped they might be known, rather than to chance the hazards of going further afield. At the same time, however, some more or less deliberate measures appear to have been adopted by employers to keep the reserve together: thus work which might have been done always by the same men was sometimes given out in rotation so as to have enough men always in close attendance for emergencies. For example, a special committee on unskilled labour set up by the Charity Organization society (1908) reported that it was found at certain London wharves that the permanent staff averaged only 70% of the minimum numbers employed on the slackest days. The remaining 30% of constant work, together with the casual work, was distributed over a large reserve of irregular hands.

From the worker's point of view, the element of chance in securing employment was evidently the salient feature. The man seeking work in the first place had to forecast the probable demand for labour at the different centres within the docks without any adequate information. At any centre he chose he had to compete with a "struggling crowd," the great majority of whom were unknown to the employer or his agent who undertook the selection of workers. The effects of this irregular and unpredictable employment upon the individual were commented on by a number of

sociologists at the end of the 19th and the early part of the 20th centuries. Speaking of casual labourers at the London docks in the 1880s, Beveridge says: "The knowledge that any man, whatever his experience, however bad his antecedents, might get a job at the Docks, attracted to their neighbourhood a perpetual stream of blackguards, weaklings and failures from every other occupation. The experience, soon made, that regular attendance was not necessary to secure selection on days when work happened to be plentiful and the daily alternations of hard exercise and idleness rapidly developed in those who came, if they had it not before, the greatest irregularity of habits and physical or moral incapacity for continuous exertion. The low physique and half-starved condition of many of the labourers made their work dear at 4*d.* an hour. The London dock casual was popularly regarded as 'the scum of the earth'; the system of dock employment was aptly described as, in effect, 'a gigantic system of outdoor relief.' All could get occasional shillings, few a decent living." (*Op. cit.*, 1930 ed. pp. 87–88, Longmans Green & Co. Limited.)

Decasualization Schemes.—Many attempts were made to introduce some measure of organization into this chaos. As a result partly of the strike of 1889, partly of the investigations of Charles Booth, the London and India Docks company initiated measures of decasualization during the 1890s and after, which included, first, the formation of registers or lists of workers to whom preference was normally given, and, second, the making of the whole of the company's dock area into a single labour market instead of a number of separate and distinct areas of employment. In the single labour market the required supplies of men were directed from a central office to the different work places. This scheme was extended when the Port of London authority was established in 1909.

During the first 30 years or so of the 20th century a number of other schemes were set up in various British ports. Thus in 1912 the port employers of Liverpool, the port-workers' trade union, the board of trade and the treasury co-operated to bring into existence the Liverpool dock scheme. Another scheme was set up in Bristol in 1916. The ministry of labour's Port Labour Inquiry committee, appointed in 1930, found 31 schemes which were at that time in operation in various ports. The report stated that by this date all major ports were involved with the exception of Glasgow and the Tyne and Wear ports, and that more than two-thirds of port transport workers were covered. The chief features of these schemes to promote decasualization were that: (1) they were all registration schemes—that is, that they involved the maintenance of a register of men who received preference in the selection of labour; (2) they were voluntary schemes, operating without any legal sanction, though generally with the assistance of the ministry of labour, which often provided secretarial or clerical help; (3) the majority of them were operated jointly by representatives of employers and of workers; (4) generally each scheme provided for the centralized engagement of labour, though it was stated that in some ports this was found to be impracticable; (5) no provision was made for guaranteed minimum income. The committee considered the question of labour wastage and recruitment—obviously an important feature of decasualization schemes—but reached no very definite conclusions. They found that the registration schemes had worked well and had brought into dock work a much better type of employee than was typical at the end of the 19th century; and they felt that registration was an essential preliminary to any decasualization scheme.

During World War II it became imperative to introduce a greater measure of organization into dock work, partly because of the general labour shortage, partly because of the effects of bombing and the need for greater flexibility of the labour force. Consequently, statutory port registration committees were set up early in the war; and under the Dock Labour (Essential Work) order, 1941, a National Dock Labour corporation, with local boards, was appointed. The order also empowered the minister to make dock labour schemes, the essential points of which were that all port workers were to be registered; that all workers, when not actually in employment, automatically entered a reserve pool and were deemed to be in the employment of the corporation; and that, when in the reserve pool, they had to report to a control point as required, and, if not allocated to jobs, received attendance money. Thus a system of guaranteed pay was a feature of these schemes.

Another phase in the process of dock labour decasualization began when, in 1946, the Dock Workers (Regulation of Employment) act was passed. This, with orders and a scheme made by the minister of labour under it in 1947, regulated the system of decasualization in Great Britain.

Provision was made for the setting up of a National Dock Labour board, which succeeded the corporation in June 1947 and became responsible for the administration of the scheme. In addition, local dock labour boards were to be set up in each port or group of ports; by the beginning of 1952 there were 25 such boards. The national board consists of a chairman and vice-chairman and not less than eight or more than ten other members, four of these other members representing dock employers and four dock workers. All the members of the board are appointed by the minister of labour after consultation with the National Joint Council for the Port Transport Industry. Local boards also consist of representatives of dock workers and of employers in equal numbers.

The chief functions of the national board are to maintain a labour force of a size suitable to current conditions, to maintain a register of employers and a register of workers and to provide for the training and welfare of dock workers. All these functions, except the first, are also functions of the local boards, and much of the work of the national board is in fact carried on through these local agencies.

Broadly speaking, only those persons whose names are on the board's register are eligible for employment in dock work. Every person whose name is on the register is required to attend at a call stand in his port at stated times, generally twice a day, for work. If none is available for him at any one of these "turns," he is entitled to "attendance money" at the rate of five shillings per turn. If he has attended a full week without obtaining work, his entitlement is increased so as to bring it up to a guaranteed week's wage, varying according to the age and medical category of the worker. The pay of those workers who have earned less in a week than the amount of the guaranteed wage is also made up to the minimum. If the worker does not report at the call stand and furnishes no adequate excuse he forfeits his claim to any payment for the week in question. Where conditions lead to a sudden temporary shortage of labour, the local board is empowered to open a temporary register until the abnormal shortage disappears. This provision, which would seem on the face of it to be contrary to the principle of decasualization, does not appear to have given rise to any great difficulties. The national board is also empowered to transfer labour from one port to another in order to equate supply and demand.

Attention was also given to the development of welfare services, including the provision of medical centres and canteens, the appointment of welfare officers, the promotion of educational activities and the supervision of benevolent funds.

The income of the national board is derived from a levy on the wage bills of the employers. This levy is equivalent to a percentage of the wage bill, the rate being fixed by the board from time to time. Out of this income the board pays attendance money and the amount necessary to make up each worker's pay to the guaranteed minimum. From it also come holiday pay, the employers' national insurance contributions and the expenses of maintaining welfare services.

The board is thus not in receipt of any public money. Moreover, although it was set up under the provisions of an act of parliament, it is not a department of government. Nor is it an employer. It may perhaps be described as the agent of the port employers, but it occupies a somewhat anomalous position which can give rise to difficult questions of practical politics.

Other European Countries and the Commonwealth.—In many other countries with large maritime interests decasualization schemes have been initiated. Such countries include Canada, Australia, New Zealand, India, France, the Netherlands, Bel-

gium, Norway and Sweden. These schemes vary considerably in detail. It may be said, however, that they all include some method of limiting the number of dockers competing for work by granting to certain of them a priority right in the port concerned. In some of the countries mentioned above the scheme operates under statutory provision: thus in Australia the Stevedoring Industry board was established by an act of 1949 and has the duty of maintaining the labour supply and of organizing and controlling waterside workers. In others, decasualization regulations are included in the collective agreements between employers and unions, and the system is thus anchored to the principle of collective bargaining. The guarantee of a minimum income is embodied in such schemes as those of Australia, France and New Zealand, in which workers receive attendance money and (in New Zealand) a guaranteed minimum wage. Some further remarks on these schemes will be found in the International Labour office report on *Decasualisation of Dock Labour* (1949). (A. F. Ws.)

UNITED STATES

The term casual labour, whether applied to demand for labour or to the people who satisfy the demand, is used in the United States to describe irregular, short-time employment of a wide variety of types. It ranges from extra help for house cleaning, snow shovelling and the like, to short-time hirings on docks and in agriculture, lumbering, contracting and other industries. Many thousands pick up a precarious livelihood at such work. Caterers, hotels and restaurants and clubs, hire casual labour for waiting table and kitchen work at banquets and other social functions; advertisers, theatres, stores and many other businesses employ people for short periods to distribute advertising matter, help load or unload trucks or other equipment, deliver merchandise or do odd jobs. A multitude of small businesses such as wood sawyers, house builders, coal and ice companies and canneries often hire short-time help. Those enumerated are illustrations of the wide range of casual jobs in the business world in general.

The United States bureau of the census enumerates, as one classification, people who involuntarily work part time. They cannot get or cannot accept steady work. The census bureau stated (Sept. 20, 1951; *cf.* bibliography) that "a disproportionate part of the involuntary part-time workers are employed in private household work where work schedules are notably unsteady irrespective of the economic climate in general." This group includes cleaning women who work by the day, men who spade gardens, clean and install storm windows, rake leaves, and do similar odd jobs around the home. Every city and town and many rural communities have casual workers depending upon such employment. In total, they are a large number of people.

A clear distinction must be made between casual jobs, *i.e.*, jobs which create a demand for casual labourers, and casual labourers as such. Casual jobs are often accepted by people who are ordinarily in regular employment but who, during unemployment, seek casual work to tide themselves over a stringency. Casual labourers are people who consistently work irregularly. They depend for subsistence on picking up short jobs. They are often physically or psychologically incapable of steady employment. In a limited number of cases, they do casual work to supplement some other type of income. But in the large majority of cases, casual work is performed by casual labourers for whom it is their dependence for livelihood. These labourers are often deficient in work capacity; some are old or some physically deficient, or both. Most of them are below par physically and psychologically. They are a normal product of uncertain livelihood, too much unemployment, and often of demoralizing life experiences. Patterns of living which depend upon picking up odd jobs are seldom desirable socially or individually.

There is a twilight zone between mere part-time employment and casual employment. In individual cases it is frequently difficult to know whether to classify certain work as merely irregular or as casual. In agriculture, for instance, with its seasonal work, thousands of work opportunities of a definitely casual type arise. Harvesting of many crops which require much seasonal labour (such as picking fruit and berries, cultivating or harvesting green vegetables, working in the onion fields in Texas, or in the sugar beet fields in Colorado, Michigan and other states) also call for a large number of people hired for very short periods, either to replace hands who have quit or to step up the job to a faster pace for a short time.

The loading and unloading of ships has been for centuries an outstanding type of casual employment (*see* above). The unceasing hiring, laying off and new hiring of longshoremen for the loading or unloading of ships; the former unpredictability of the arrival times of ships; and the daily uncertainty about both the day's demands for labour and the number of men available, kept the dock situation in a constant state of flux. The ease with which unemployed men from other industries could come to the docks to pick up a few dollars intensified the competition for work, while the labour surplus ordinarily accumulated around the docks played into the employers' hands. Large numbers of longshoremen frequently found themselves on poor relief.

The unionization of U.S. longshoremen, particularly from the early 1930s onward, enabled the longshoremen to prevent easy access to longshore work by refusing to work with nonmembers or requiring nonmembers accepted for employment to have union permits, thus establishing union control over the labour supply. They established "dispatching halls" (hiring halls) in many ports, supervised by a joint committee of employer and union representatives or by the union. The hiring-hall system, which began at Seattle, Wash., in 1939, did much to change the casual labour situation on the docks to a regularized system of employment. The halls enabled the longshoremen to hold the dock work for those who made it their regular occupation and to divide the available work equitably among them. It insured the employers experienced men systematically dispatched to the boats as needed. The system did not work without frictions, disputes and delays in the handling of shipping, but it markedly diminished the casual character of longshore work.

The relatively full employment which prevailed in the years after 1941 did more than anything else to counteract casual employment. With industry, mining, transportation and agriculture all operating at a high level of productivity, there were more opportunities for workmen of less than maximum efficiency to get steady employment and a noticeable reduction in the proportion of casual workers in the industrial population.

CASUALTIES, in military use, the losses of a force in war by death, wounds, sickness, desertion or any other cause (from Lat. *casus*, that which falls out). The duty of dealing with all casualties from wounds or sickness falls to the medical services, the personnel of which treats each case from the moment of its occurrence to the eventual recovery or death of the patient.

CASUAL WARD, the name given, under the British poor laws in force between 1834 and 1948, to a building for the purpose of giving temporary shelter to vagrants.

Under the poor law as reformed in 1834, the primary duty of boards of guardians was to relieve destitute persons within their districts. Gradually, however, it was extended to the administering of relief to vagrants, popularly called tramps and officially termed casual paupers. The casual ward was generally adjacent to the workhouse or poor law institution.

Any vagrant or unemployed person walking from place to place and seeking work usually obtained an order for the casual ward from the relieving officer or his assistant; vagrants were searched—usually perfunctorily—and deprived of money and tobacco, which were restored to them on discharge. They were given a bath on admission and a meal, usually sugarless cocoa and a piece of bread. For the night the clothes of the inmates were taken away (and sometimes disinfected) and a rough nightshirt provided. Sleeping accommodation on the floor or a truckle bed was pro-

vided either in cells or associated wards. In return for the food and lodging, tasks of wood sawing or chopping, digging, oakum picking or scrubbing floors were imposed, though in many of the wards the obligation was not too strictly enforced.

Poor Law Act, 1930.—After 1918 as a result of postwar conditions and industrial disputes the great increase in the numbers of wayfarers applying for assistance to the poor law guardians threw the system out of gear and, following the abolition of the boards of guardians by the Local Government act, 1929, and the transference of their functions to the county and borough councils, a reorganization was affected by the Poor Law act, 1930, supplemented by various orders. The provision of and admission to casual wards became the business of the public assistance committees of the councils, and joint vagrancy committees were established throughout the country to bring about a uniform system and effect economies in expenditure. The casual was admitted and supervised by trained officials, and ordinarily was not allowed to discharge himself before the second morning (excluding Sunday) following admission unless he had a current vacancy ticket given him by an employment exchange. (This was a card showing an appointment with a prospective employer, and entitled its owner to leave the casual ward immediately without detention.) His clothing was taken and cleaned if necessary; money and other articles were also taken from him and the cost of relief deducted before return; a day room and proper sleeping accommodation had to be provided, also a clean towel; and any case of infectious disease or mental illness had to be reported to the ministry by the medical officer, who had to visit the ward and examine every casual therein once a month.

National Assistance Act, 1948.—During World War II casual wards in England and Wales were closed. By the end of the war some had fallen into disrepair and some had been taken over permanently for other uses. Furthermore, between 1939 and 1945 the number of vagrants fell greatly; and though there appears to have been a steady increase in the years immediately after the war, the numbers, by the end of 1951, were apparently still far short of those in prewar years.

The 1948 act changed the administration of the casual wards. These, henceforward to be known as "reception centres," were placed under the National Assistance board. The great majority of the centres (which were fewer in number than the old casual wards) were housed in the identical buildings which had previously been used for such wards. Shortage of materials had made it impossible to erect new buildings, though it would have been preferable to do so. Again, although the responsibility for these centres was transferred to the National Assistance board, the act empowered it to make local authorities its agents in carrying out these duties; and this it ordinarily does.

The regimen of the English casual ward between 1931 and 1939, summarized above, was followed in reception centres; but while the standing principle of the prewar poor law administration in England and Wales had been to keep the vagrant moving, the major change made by the 1948 act was that vagrants should be encouraged to stay at the centres until some constructive action could be taken for their benefit. (A. F. Ws.)

CASUARIIDAE: *see* CASSOWARY.

CASUARINA, a genus of odd trees of the Casuarinaceae family containing about 35 species, chiefly Australian, but a few Indo-Malayan. The long whip-like green branches are longitudinally grooved and bear at the nodes whorls of small scale-leaves, the shoots resembling those of *Equisetum* (horse-tail). The flowers are unisexual. The staminate are born in spikes, each flower consisting of a central stamen which is surrounded by two scale-like perianth-leaves. The pistillate are borne in dense spherical heads; each flower stands in the axil of a bract and consists of two united carpels flanked by a pair of bracteoles; the long styles hang out beyond the bracts, and the one-chambered ovary contains two ovules. In the fruit the brateoles form two woody valves between which is a nutlet; the aggregate of fruits resembles small cones. Pollen is transferred by the wind to the long styles. The pollen-tube does not penetrate the ovule through the micropyle but enters at the opposite end—the chalaza (*see* ANGIOSPERMS). The wood is very hard, and several species are valuable timber trees. From a fancied resemblance of the wood to that of the oak these trees are known as "oaks," and the same species has different names in different parts such as "she-oak," "swamp-oak," "iron-wood" and "beef-wood." Several species are cultivated in the subtropical parts of the United States, especially the beef-wood (*C. equisetifolia*), which has become widely naturalized in Florida. *See* J. H. Maiden, *Useful Native Plants of Australia* (London and Sydney, 1889).

CASUISTRY was originally a term of disparagement. Coined in the first quarter of the 18th century from "casuist," perhaps by analogy with "sophistry," it expressed the contempt of emancipated "common sense" for all the labour and nicety of reasoning which the preceding century had expended on resolving cases of conscience. It afforded a vehicle also for the confused popular notion that casuistical activity was at once subversive of morality and an instrument of priestcraft. But in time, although the tendentious usage did not die (indeed it persists still in quarters where ratiocination in moral matters is suspect), the word grew respectable. It now signifies, like the French *casuistique,* that part of Christian moral theology which determines the morality of particular actions in particular circumstances, especially such as are apt to puzzle the conscience. The discovery that circumstances alter cases not being peculiar to Christianity, the name "casuistry" is given also to the application of any moral system, Christian or not, to concrete situations; but here in the main only casuistry as understood within the Roman Catholic and Anglican churches will be considered.

Moral theology may be described as the application of Christian dogma to human life. The scope of casuistry within this field is not, and probably cannot be, defined exactly. It is generally admitted that the casuist's concern is not with the rights and wrongs of actions considered in the abstract, but with the problems facing particular agents in particular situations; but opinions differ concerning the relation of his special function to general moral theology on the one hand and to the work of pastors, spiritual directors and confessors on the other. Most commonly he is represented as an expert consultant, who applies the "conclusions" of general moral theology to the diverse situations which confessors and others refer to him, in order to determine what moral obligations those situations present. On this view casuistry is the link between general moral theology, which is assumed to have finished its work when it has expounded the law of God more or less in abstraction from variable circumstances (though of course no formulation of the law is possible at all without reference to some circumstances), and the pastoral art, which enters intimately into the minds and situations of those whose consciences are actively engaged. Some would even further restrict casuistry to helping confessors in their judicial, as distinct from their advisory, capacity.

Although many casuists have accepted these limitations, it is doubtful whether casuistry can encompass its proper end under them. That end cannot be less than to enlighten puzzled consciences, that they may discern God's will and vocation in their actual situations. Therefore the casuist should not stop at determining strict moral obligation (though that is an essential part of his work), still less at helping the confessor to make ex post facto judgments with a view to absolution, but should focus whatever light his science affords for the direction of souls "in the ways of truth, so that they neither decline to the right hand nor to the left" (George Herbert, *A Priest to the Temple,* 1652). Since division of labour is necessary, the expert casuist will more often act as consultant than have immediate contact with those who need guidance. Indeed it is as a rule better that he should not be pastorally involved in the matters that he considers, for personal sympathy with hard cases and firsthand experience of the harm done by prevalent excesses can sway the judgment toward laxism or rigorism. But the smaller the degree of abstraction that underlies his resolutions, and the more fully he grasps the interior as well as the exterior circumstances of the agent, the more perfectly he fulfils his ministry.

Casuistry cannot attain its end, thus conceived, simply by

taking over "conclusions"—moral generalizations and axioms—from general moral theology and relating them to circumstances. Often the right resolution of a case requires direct reference to the fundamental mysteries of the Christian faith or fresh consideration of the God-given natures and ends of created beings. Whenever casuists cease to keep open their communications with ultimate theological truth and rely merely on ready-made generalizations and casuistical precedents, their science degenerates into a sort of moral case-law, unillumined by the Gospel. Moreover it is vital to recognize, in any estimate of the relation of casuistry to moral theology at large, that the resolution of particular cases, especially such as embody unprecedented circumstances, may throw new light on the moral law and so require that some "conclusion" of moral theology be reconsidered. It is thus that casuistry, adequately conceived, challenges the legalism which equates the law of God with current moral generalizations.

In every age the major part of the church's casuistical activity is exercised by word of mouth, often under the seal of the confessional, or in private correspondence. Published books are usually by-products of the principal work of casuists, many of whom—and among them the best—are content to write on souls alone. It follows that a literary history of casuistry can offer only a partial and to some extent a misleading view of the matter. Nevertheless it can be asserted that nothing that could be called a science emerged before the middle ages. Earlier casuistical reasoning, such as appears not only in the writings of the Fathers but in the New Testament itself (for instance, in I Corinthians), was necessarily occasional and unsystematic. Scientific casuistry could not establish itself until the 12th-century renaissance in western Christendom had made possible the articulation of theology, and the analysis of human action had so far progressed as to prevent confusion between the objective nature of an act, its purely circumstantial accompaniments and the subjective purpose of its agent. The fact that no comparable foundation was laid in the eastern church goes far to explain why scientific casuistry has been confined almost wholly to the western.

The rapid growth of the new science in the 13th century formed part of a striking development, largely Dominican in inspiration, of pastoral and penitential theology. The increasing importance of the sacrament of penance in the life of the church, to which the fourth Lateran council (1215), by its ruling on yearly confession to the parish priest, gave authoritative recognition, and the great expansion of canon law since the *Decretum* (between 1140 and 1150) of Franciscus Gratianus, had stimulated demand, both in the schools and in the confessional, for ampler and more systematic guidance than the old penitential books had ever afforded; and the need was met by a notable output of penitential and casuistical *summae*, among which the *Summa de casibus poenitentialibus* (between 1222 and 1230) of the eminent canonist St. Raymond of Peñafort and the *Summa confessorum* (between 1280 and 1298) of John of Freiburg were specially influential.

After sharing in the 15th-century lapse of theology into academic quibbling, casuistry again underwent, from the middle of the 16th century up to the middle of the 17th, remarkable development and expansion. The causes were various: theology, moral as well as dogmatic, forced by the controversies of the day to reexamine its foundations, was invigorated by renewed study of the great schoolmen, especially of St. Thomas Aquinas; contact with the New World and rapidly changing conditions of life brought fresh moral problems; and the intense activity of the new religious orders, especially the Society of Jesus, in the confessional and in spiritual direction both provided the casuist with material to work on and stimulated demand for casuistical literature.

Nor was it only in the Roman communion that casuistry flourished. In England at any rate "casuistical divinity" was very highly esteemed, by Puritans as well as by Anglicans, by laymen as well as by ecclesiastics.

Yet this, the great age of the casuist, in which he perfected his technique and demonstrated his concern with the whole of human life, was also the age in which he attracted the odium that gave the word "casuistry" its original meaning. The indignation against the Jesuits so bitingly voiced by the Jansenist Blaise Pascal in his *Provincial Letters* may be partly discounted, as springing from the rigoristic temper which feels that any qualification of moral precepts to suit circumstances undermines the absoluteness of the moral law; and the 18th-century dislike of casuistical divinity was due in the main to reaction against the epoch just past and to defects in the 18th-century mind. Nevertheless, when all is said, one has only to study, for instance, the work of Antonino Diana (1586–1663), whose *Resolutiones morales* were widely used, to see that, though Pascal overstated his case, he undoubtedly had a case to state. Confirmation of this may be found in the Anglican Jeremy Taylor's preface to his *Ductor Dubitantium* (1660).

While Taylor had no quarrel with casuistry as such, being a casuist himself, he was intensely critical of the casuistry of the Counter Reformation; and, even when his prejudices against Rome and against probabilism and his not altogether well-informed sympathy with Jansenism have been allowed for, the substance of his criticism remains.

It seems that the preoccupation with penance and the reliance on authorities which had been appropriate to the mediaeval situation were now having undesirable effects. First, the prime concern of many casuists being to assist the confessor (and the confessor as judge rather than as spiritual guide), their aim in writing was often nothing more exalted than to distribute the actions they considered under the three not very inspiring heads of "mortally sinful," "venially sinful" and "not sinful."

Within the terms of reference they had accepted this was probably inevitable, and in the hands of prudent confessors their work was doubtless put to good use. For in an age of earnest and skilful spiritual direction no less than of casuistry, when St. Francis de Sales (1567–1622) and many others taught the pursuit of perfection to Christians living in the world as well as to religious, priests cannot be presumed to have let their penitents believe that the resolutions of casuists marked the goal of Christian endeavour. Nevertheless the impression that casuistry offered a substandard was made, and persisted.

Secondly, the habit of relying too much on authorities—in other words, of judging opinions by the reputation of their authors as much as by their intrinsic reasonableness—caused the new and useful tool of probabilism to be abused. In itself probabilism (*q.v.*) means giving the benefit of the doubt. A man is doubtful whether, in the circumstances, he is bound by a certain obligation. Having canvassed the pros and cons, he finds substantial arguments (intrinsic probability) on both sides and has difficulty in deciding which way the balance inclines. Suppose, however, that he thinks there is rather more to be said in favour of the obligation than against it: is he then morally bound to fulfil it? The probabilist answers "No"; for as long as there is against the obligation a reasonable case which defies refutation, the obligation necessarily remains doubtful; and doubtful obligations cannot bind the conscience. Probabilism does not assert that it is "right" for the man not to fulfil the obligation: it merely says that, if he decides not to do so, he cannot, in view of the doubt, be accused of acting irresponsibly. But sometimes the agent is incapable of marshalling and evaluating the pros and cons. In such a case he may reasonably rely on extrinsic probability, that is, on the opinion of others who may be supposed to know what they are talking about; and if opinions differ, probabilism will again apply. Of course, if a man were found always taking the benefit of the doubt, we should begin to question his moral sincerity; but, granted conscientiousness, probabilism is a reasonable and prudent way of dealing with such problems. It is a different matter, however, when casuists, taking up probabilism too enthusiastically, consistently end their consideration of disputed questions by declaring two or more conflicting opinions probable; and the uncertainty which is spread by such practice is dangerously magnified if purely extrinsic probability is admitted, that is, if casuists, instead of carefully examining the Rev. Marcus Brutus' arguments, say in effect, "Brutus says so and so; and Brutus is an honourable man." But that is what many writers of the 16th and 17th centuries did, thus opening the door to laxity; for, as Jeremy Taylor remarked, casuists who too often conclude *alii aiunt, alii negant;*

MEMBERS OF THE CAT FAMILY FOUND IN AFRICA, ASIA AND AMERICA

1. Lion (*Panthera leo*), one of the two largest of the cat family, the other a tiger. It is found in Africa, Mesopotamia, Persia and India
2. The Bengal tiger (*Panthera tigris*), a fierce beast of prey which sometimes, especially in old age, becomes a man-eater
3. Lioness (*Panthera leo*), about a foot shorter than the adult male and generally considered more dangerous when attacked
4. Puma or mountain lion (Felis concolor), a large American cat extensively distributed from Canada to Patagonia. It is of a uniform colour
5. Tigress (*Panthera tigris*), somewhat smaller than the male but equally aggresive, especially when protecting her young
6. Leopard cat (Felis bengalensis), a small, savage wildcat of tropical Asia that feeds largely on game birds
7. Ocelot (Felis pardalis), an American forest cat ranging from Texas to Paraguay. Its fur is yellow or grey marked with spots
8. The red or bob-tail lynx (Lynx rufus), a North American species that ranges south to Mexico. Its reddish summer coat is less spotted
9. Jaguar (*Panthera onca*), the largest of American cats. It ranges from Texas to Patagonia and sometimes develops into a man-eater
10. Cheetah or Hunting Leopard (*Acinonyx jubata*), so called because it is used in the hunting of game. It is a native of Africa and Asia
11. The snow-leopard (*Panthera uncia*), an inhabitant of highland Central Asia. Its name is suggested by its grey spotted fur
12. Serval (*Felis serval*), an African wildcat that preys on small quadrupeds and is prized by the natives for its skin, which is a spotted yellow

utrumque probabile ("Some say this, some that: both opinions probable") "entertain all interests, and comply with all persuasions, and send no one away unsatisfied."

It was the project of the English school of casuists—the Calvinists William Perkins (1558–1602) and his disciple William Ames (1576–1633), the Anglicans Joseph Hall (1574–1656), Robert Sanderson (1587–1663), Jeremy Taylor (1613–67) and John Sharp (1645–1714), and Richard Baxter (1615–91), who refused to conform in 1662—to purge casuistry of these blemishes: to banish the excesses of probabilism and make casuistical divinity a guide to holy living instead of merely the science of judgment on past sins, with a usefulness that would not be confined to the confessional. Although good work was done, the aim was not to be realized. The 18th century had no patience at all with the previous century's addiction to cases of conscience; and moral theology to all intents vanished from the Church of England for more than 100 years. Within Lutheranism it had already died. Indeed, if Karl Barth is right about the true nature of Protestantism, there is no room in it for a moral theology, let alone casuistry; and it is precisely the element in Emil Brunner's thought which Barth regards as Catholic and heterodox that enabled him to write *The Divine Imperative* (Eng. trans., London, 1937) and *Justice and the Social Order* (Eng. trans., London, 1945). It was therefore left to the Church of Rome to keep the torch of casuistry alight, albeit with a wavering and smoky flame, through a murky period, until the papal condemnation of laxist errors and the work of St. Alphonso Liguori (1696–1787) had prepared the way for better things.

The 19th-century revival in the Church of Rome produced some sound but on the whole uninspired manuals of moral theology, mostly with a casuistical turn; but the Anglican rediscovery of moral theology begat very little writing, the only work of casuistry worth mention being W. W. Webb's *The Cure of Souls* (New York, 1892). In the 20th century both Roman and Anglican writers came to pay considerable attention to contemporary sexual, matrimonial and medico-moral questions; and here an odd reversal is to be noted in that, while many Anglican conclusions (some of them obviously products of amateur casuistry) revived the *alii aiunt, alii negant; utrumque probabile* which Jeremy Taylor deplored, Roman casuistry grew if anything too rigid. By the middle of the century moral theology was engaged in re-examining its scriptural and dogmatic foundations, its methodology and aims and its relation to ascetics (*cf.* G. Gilleman, S.J., *Le Primat de la charité en théologie morale*, Louvain, 1952; and B. Olivier, O.P., and others, *Morale chrétienne et requêtes contemporaines*, Tournai, 1954). There were signs that reforms might ensue, the effect of which upon casuistry could not yet be foreseen.

Kelly, *Marriage, Morals and Medical Ethics* (Dublin, 1952); and the *Cahiers Laënnec* (Paris, various dates) on medico-moral questions; also certain reports—commission appointed by the archbishop of Canterbury, *Artificial Human Insemination* (London, 1948); commission appointed by the archbishops of Canterbury and York, *The Church and the Atom* (London, 1948); Social and Industrial Commission of the Church Assembly, *Gambling: An Ethical Discussion* (London, 1950); Church of England Moral Welfare Council, *Human Sterilization* (London, undated). (G. B. B.)

CASUS BELLI, a situation said to justify a state in initiating war. The United Nations charter provided that warlike measures are permissible only if authorized by the Security council or the general assembly, or if necessary for "individual or collective self-defence" against "armed attack." (*See* ARBITRATION, INTERNATIONAL; WAR.) (Q. W.)

CAT, the name of the well-known domesticated animal *Felis catus*, but in a wider sense employed to denote all the more typical members of the family Felidae. The word "cat" is also applied to other objects, in all cases an application of the name of the animal. In mediaeval siegecraft the "cat" was a movable penthouse used to protect besiegers when approaching a wall or gateway.

"Cat" or "cat-head," in nautical usage, is the projecting beam on the bow of a ship used to clear the anchor from the sides of the vessel when weighed. The name is also used for a type of vessel, formerly used in the coal and timber trade in northeast England; it is still applied to a small rig of sailing boats. The instrument of punishment, generally called the "cat o' nine tails," consists of a handle of wood or rope, about 18 in. long, with nine knotted cords or thongs.

Origin of the Domestic Cat.—Although bones of cats were found in the dwellings of ancient cavemen, it is very probable that these cats were not domestic. About 3000 B.C. in Egypt, when agriculture had become well established, the Egyptians tamed the cat to protect their stores of grain. These animals proved so valuable that they were later considered to represent one of the gods, perhaps to give cats better protection. The wild species from which they were derived was the African wild cat (*Felis lybica*), one race of which occurred in Egypt. This is a gray cat with a slightly buffy cast, marked with blackish stripes and spots on the body and legs, the tail with a black tip and several rings, and the feet dusky. Its hair is short and the build and general proportions are like those of the common house cat. Modern domestic cats interbreed freely with the African wild cat.

From Egypt domestic cats spread slowly throughout the civilized world. In Europe they undoubtedly interbred with the European wild cat (*Felis silvestris*), a very closely related species with longer fur and tail. In the Egyptian wild cat the pads of the toes are wholly black, and the black extends up to the heel. In the European wild cat, on the other hand, the black is limited to a small round spot on the pads. In domestic cats with wild colouring the soles of the hind feet correspond in this particular with the Egyptian wild cat.

Two distinct types of so-called tabby cats are recognized. In one the pattern consists of narrow, vertical stripes and in the other of longitudinal or obliquely longitudinal stripes, which, on the sides of the body, tend to assume a spiral or whirl arrangement. One or other of these types is to be found in cats of almost all breeds, and there appear to be no intermediate stages. The striped type is the wild pattern of both European and African wild cats; but the origin of the blotched pattern was probably a mutation.

Tame cats from Egypt were imported into Italy at an early date by Phoenician traders and became established long before the Christian era. Their progeny spread over Europe, more or less crossed with the indigenous species. Remains of cats found in Roman villas at Silchester and Dursley are probably referable to the domesticated breed. The earliest record in Great Britain dates from about A.D. 936 when Howel Dda, prince of south central Wales, enacted a law for their protection.

There are fewer breeds of domestic cats than there are of dogs, and the differences are not so great as those shown in the various breeds of rabbits. Except in a very few cases there is no need to suppose crossing with other species to explain the peculiar characters of certain cats.

All animals are liable to show individual variation which can be selected and established in pure strains. Larger mutations occur rarely but are likely to make their appearance from time to time.

Breeds of Domestic Cats.—Apart from the division on the basis of their pattern, mentioned above, domestic cats are divided into short-haired and long-haired groups. The former resemble the wild cats of Europe and Africa, the long-haired types having developed in Persia and Afghanistan. Cats of both groups vary, on the one hand, toward melanism, black colouration like that seen in many wild species of cats, while on the other hand white cats are fairly common. A nearly white tiger and a similarly coloured cheeta have been reported, and an albino leopard is known,

but albinism is very rare among all species of Felidae. Tortoise-shell cats are generally females with a mixed colour of black and yellow (and white); yellow or sandy cats are usually males. The genetic factors for red and black are thought to be situated in the sex chromosomes, which accounts for the peculiar inheritance of these colours.

There are two varieties of the long-haired cats, the Angora and the Persian. The former has a pointed head, long nose, and long, silky fur. The Persian (which may come from Afghanistan) has a rounded face and coarse fur; its tail is thickest near the tip. In the United States and parts of Europe the latter cat has replaced the Angora. These long-haired cats are often thought to have been derived from the manul (*Felis manul*) of the steppes of central Asia, but long-haired breeds of goats, rabbits and dogs indicate that it is not necessary to suppose such an unlikely ancestry.

The tailless or Manx cat, in which the tail may be represented merely by a tuft of hair without any bone, is common in the far east. In the Malay regions and Philippines normal long-tailed cats are rarely seen, and kink-tailed or short-tailed cats predominate. Whether the tailless cat reached the Isle of Man from elsewhere or whether it developed there as a sudden independent mutation is not known. The fur is usually longer and more lax than in ordinary cats. In New England and the middle Atlantic states they are often called "rabbit cats," and people suppose they are part rabbit, incredible as such a crossing would be. The cry is said to differ somewhat from that of tabby cats.

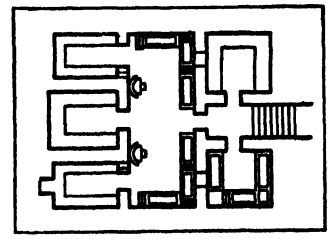
Among the domestic cats of India, spotted colouring, much like that of the Indian desert cat (*Felis constantina ornata*) is common. This cat is a close relative of the African wild cat, and crossing between it and domestic cats is quite possible.

The Abyssinian breed is characterized by lack of spots and stripes on the body, each hair being "ticked" like that of a wild rabbit (known to geneticists as agouti). The head and neck retain the typical markings of the African wild cat and the tail ends in a black tip. The colour is typically reddish brown. The fur is short, the ears relatively large and occasionally tipped with long hairs. Ordinary striped tabbies sometimes produce kittens with this type of colouration, and there is little question but that this breed originated entirely from the African wild cat, probably through the Egyptian cat.

By far the most remarkable of the domestic breeds is the Siamese cat. It was first imported into England in 1884 and reached the U.S. in 1895; it became popular and numerous in both countries. Siamese cats often have kinky tails and cross-eyes, defects which breeders have not been able to eliminate from the strain. The head is rather long and pointed, the body also elongate, the hair sleek and short, and the eyes blue. The general colour is cream or buffy, with the face, ears, paws and tail dark chocolate-coloured in a variety in which the eyes are yellow. The young are white. Temperature modifies the development of the colour, less blackish developing under warm conditions, while in cold the entire animal darkens more than normally. The Siamese type of colouration is known in rabbits and other animals, in which it is often called "Himalayan." In the several thousand years cats have been in Siam, the mutation undoubtedly appeared and was fixed by selection and careful breeding. After 1924, several strains of long-haired Siamese cats were produced scientifically by crossing with Persians and inbreeding.

Numerous clubs have been founded in Europe and North America to encourage the breeding of cats and to promote cat shows. Short-haired breeds are rather easy to manage, but the long-haired varieties need more care and when shedding are nuisances.

European Wild Cat.—The wild European species, *F. silvestris*, conforms closely in pattern to the striped phase of domestic tabby but is brownish gray or buffy. The hair of the tail is long, especially toward the tip, which gives a club shape to this member. The geographical range of the wild cat formerly included Great Britain, central and southern Europe, and portions of central Asia. It is now, however, much reduced in numbers and it is doubtful if it is found anywhere without at least a trace of the domestic form in its constitution. In Great Britain wild cats survive only in some Scottish forests. Remains of the wild cat occur in English caverns; in Ireland the wild species has apparently been unknown during the historic period.



The favourite haunts of the wild cat are mountain forests where rocks or cliffs are interspersed with trees. Crevices in the rocks or the hollow trunks of trees afford sites for the lairs, where the young (2 to 5) are produced and reared. The kittens, usually born in May, are at first blind, although furred. Wild cats are described as some of the most ferocious and untamable of all animals. How far this lends support to the view of the origin of our domestic breeds is uncertain. Hares, rabbits, field mice, water rats, rats, squirrels, moles, game birds, pigeons, and small birds form the chief food of the wild cat, while fawns of roe deer are sometimes killed.

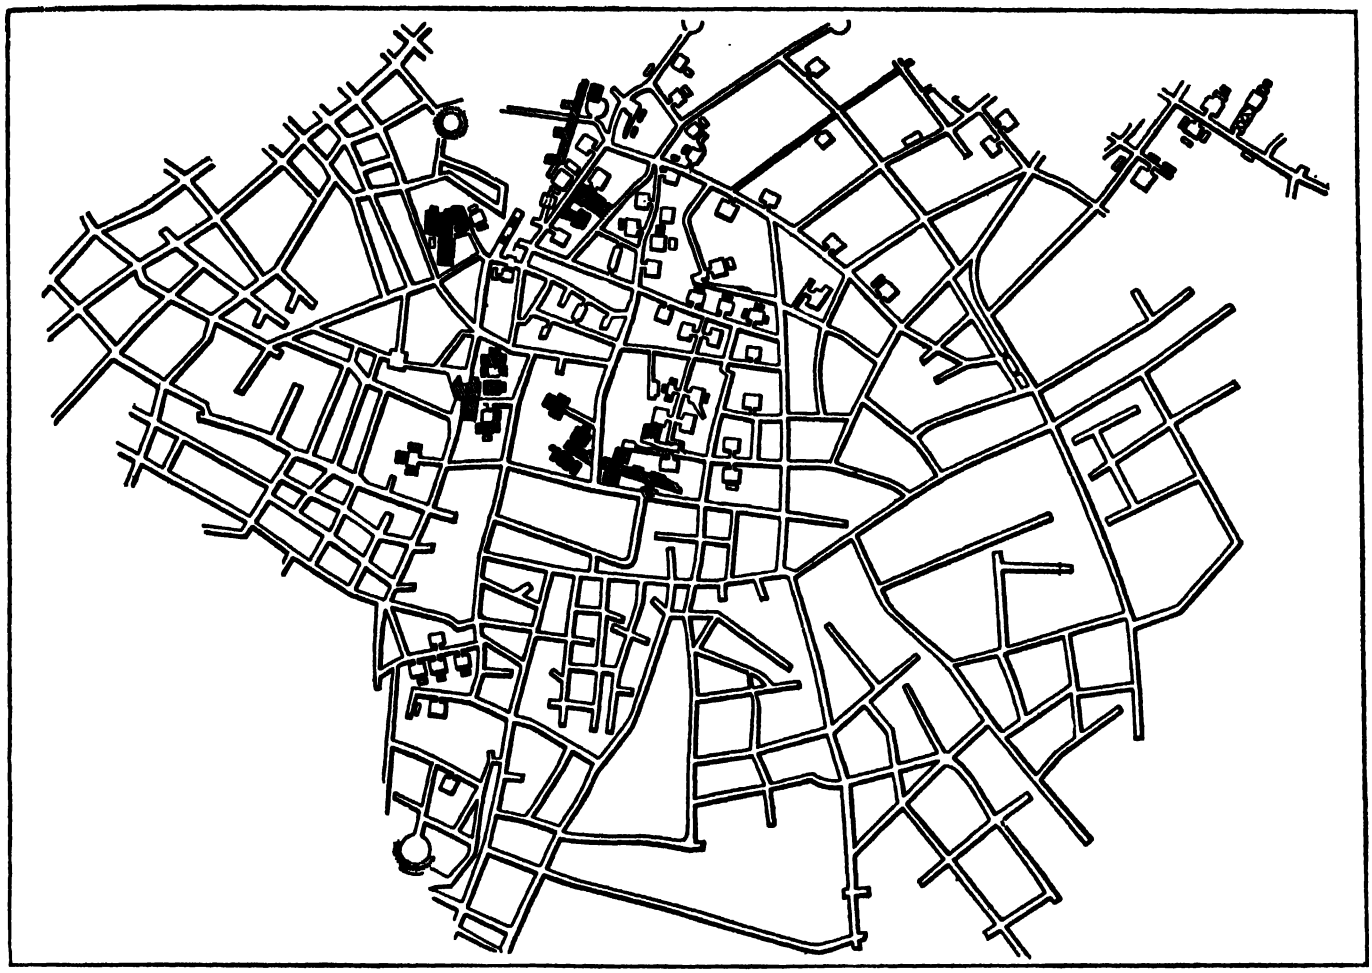
CATACLYSM, a great flood (Gr. κατακλυσμός, a deluge). In geology an overwhelming catastrophe producing sudden changes in the earth's surface; figuratively, any violent change that sweeps away the existing social or political order.

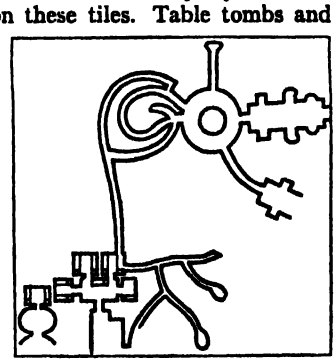
CATACOMBS. Tombs hewn in solid rock were used by the Etruscans as independent family burial places, grouped together. They often rise in the hillside by tiers or are on the same level branching off into streets and alleys. Their plan is for the most part that of a house and the walls are often covered with paintings in an archaic style in red and black. At Poggio Gaiella, near Chiusi, the ancient Clusium, is a cemetery with a sepulchral chamber containing a large hall about 25 ft. in diameter supported by a cylindrical rock pillar. Opening out of this and other chambers are low winding passages, just large enough for a man to creep through, and this tomb has been surmised to be that of Lars Porsena, king in his day of Etruria (*see* fig. 2).



In the days of the republic inhumation was general and the bodies of the Scipios and the Nasos were buried in still existing catacombs, the term applied by transference to subterranean excavations for the interment of the dead. Originally it designated the natural configuration—in hollows—of a district close to the Appian way (*see* ROME). In the vaults below the church of St. Sebastiano lay, according to tradition, the bodies of the apostles St. Peter and St. Paul for seven months until removed to the basilicas which bear their names. The place became an object of pilgrimage and its name κατακυμβας, "by the hollow," developed as a generic name for all burial places of the same kind.

FROM DENNIS

FIG. 1.—PLAN OF ETRUSCAN TOMB AT CERVETRI



Rome is built upon a rock and the three strata named by geologists *tufa litoide, tufa granolare* and *pozzolāna* have all been exploited. The *tufa litoide* is quarried as building stone. The catacombs of Rome—the most extensive known—are constructed in this stratum alone as it enabled the engineers to form vertical walls for the galleries in which the dead were placed and to work with comparative ease. The pozzolana used as an ingredient for mortar was worked from the lowest stratum so that in spite of old erroneous persistent beliefs the burial places are distinct from the pozzolana, excavated in different strata, though here and there starting from the same level. The catacombs form a vast labyrinth of narrow galleries usually from 3 to 4 ft. wide with small chambers at intervals, excavated at successive levels (fig. 1). The dead are buried in the galleries in long horizontal recesses in the walls, tier upon tier, even to 12 ranges. The galleries generally run in straight tiers, at the same level, in storeys (seven in one part of the cemetery of S. Calixtus), and intersect at various angles (*see* fig. 3). The graves (*loculi*) were usually parallel to

FROM MARTIGNY

FIG. 3.—PLAN OF PART OF THE CEMETERY OF S. AGNESE AT ROME

the gallery in Christian cemeteries, but in pagan areas the recess was usually at right angles. Some loculi held four or more bodies, most held one (fig. 5). They were carefully closed by slabs of marble or huge tiles cemented together. When an epitaph was set up, it was painted or engraved on these tiles. Table tombs and arched tombs are also found. Sarcophagi are rare. The family vaults—cubicula—were small apartments, usually rectangular, sometimes circular or polygonal, opening from the main corridors and frequently ranged regularly along the sides of the galleries. Loculi were cut for later burials in the same family area and the inscriptions and mural decorations were frequently damaged or destroyed. The funeral feast was celebrated by the family in its vault, both on the day of burial and on the anniversary. The Eucharist, the invariable accompaniment of funerals in the early Christian Church, was celebrated here, and in some of the catacombs are larger halls and connected suites of chapels which may have been constructed for congregational worship in the days of persecution (fig. 4). Baptisteries have been discovered. The catacombs were also used as places of refuge, for which they were admirably adapted, both by the intricacy of their design and by access through secret passages to sand quarries and the open country.

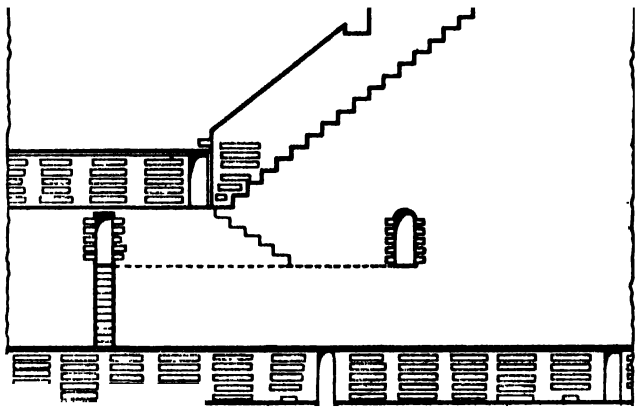
FROM DENNIS

FIG. 2.—PLAN OF A PORTION OF THE PRINCIPAL STOREY IN THE POGGIO GAIELLA CEMETERY

Almost without exception they had their origin in small burial areas, the property of private persons, and their great development was due to the spread of Christianity and the burial of the dead in this manner conformed to Roman usage. There was no reason for secrecy and since interment in rock-hewn tombs had been practised in Rome by Jewish settlers before the rise of the Christian Church, the practice may well have been popularly, perhaps correctly, associated with the Jewish population which contributed elements to the new religious order. At a later period the grave diggers seem to have acquired or to have established a kind of property in the catacombs and to make new graves recklessly destroyed the religious paintings on the walls. The major part of the catacombs belong to the 3rd and early part of the 4th centuries. By A.D. 354 when St. Jerome visited them, interment in them had become rare. By the time of Pope Damasus (A.D. 366–384) they had become the resort of pilgrims. They were adapted to this by the orders of the pope. The works of art were restored. The epitaphs were renewed. In this latter work he employed an engraver named Furius Philocalus whose work can be recognized at once.

As a result the improvements described have lessened the value of the catacombs as memorials of the religious art of the 2nd and 3rd centuries. Subterranean interment ceased with the sack of Rome by Alaric in A.D. 410. The catacombs shared in the destruction of Rome by the Goths in the 6th century and by the Lombards at a later date. Pope Paul I. and Pope Pascha I. found them in such decay and pollution that the holy relics they contained were translated elsewhere and the catacombs soon ceased to attract pilgrims. By degrees their existence was forgotten and they were discovered by chance in 1578 and have been studied, explored, investigated and described by scholars such as Baronius, Antonio Bosio (d. 1629), Marc Antonio Boldetti (*c.* 1720), Seroux d'Agincourt (1825) Raoul Rochette and most notably in recent times by Father Marchi of the Society of Jesus. Additions to our knowledge have been made by de Rossi and include the rediscovery near the catacomb of Priscilla, on the Via Salaria Nuova,

of the Cosmeterium Jordanorum, first found in 1578 but soon afterwards choked up and lost. It is possible now to identify the tombs of martyrs like Nereus and Achilleus, said to have been baptized by St. Peter, who with their mistress Petronilla, of the Aurelian family and the spiritual daughter of St. Peter, suffered death for their faith under Domitian. Many of the names of persons mentioned in the Epistles of St. Paul are found here and every fresh excavation yields similar evidence.



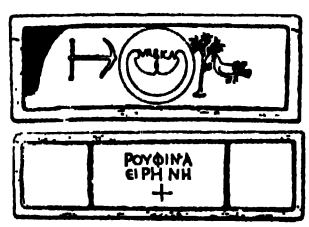


FIG. 4.—SECTION OF GALLERIES AT DIFFERENT LEVELS IN THE CATACOMBS OF ROME

At Syracuse there are very extensive catacombs known as "the Grottos of St. John." There is an entire underground city with several storeys of larger and smaller streets, squares and cross ways cut out of the rock; at the intersection of the cross ways are great circular halls of a bottle shape, like a glass-house furnace, lighted by air shafts. The galleries are generally very narrow, furnished on each side with arched tombs, and communicating with family sepulchral-chambers closed originally by doors, the marks of the hinges and staples being still visible. The walls are in many places coated with stucco adorned with frescoes including palms, doves, *labara* and other Christian symbols. This cemetery differs widely in arrangement from the Roman catacombs.

The catacombs at Malta are near the ancient capital of the island. The passages were all cut in a close-grained stone, and are very narrow, with arched ceilings, running very irregularly, and ramifying in all directions. The greater part of the tombs stand on either side of the galleries in square recesses (like the table-tombs of the Roman catacombs) and are rudely fashioned to imitate sarcophagi. The interments are not nearly so numerous as in other catacombs, nor are there any vestiges of painting, sculpture or inscriptions. At Taormina in Sicily is a Saracenic catacomb, also figured by Agincourt. The main corridor is 12 ft. wide, having three or more ranges of *loculi* on either side, running longitudinally into the rock, each originally closed by a stone bearing an inscription.

ROM DE ROSSI

FIG. 5.—LOCULI IN CATACOMBS OF ROME. GRAVES OF URBICA AND RUFINA

In Egypt we find a small Christian catacomb at Alexandria. The *loculi* here also are set endways to the passage. The walls are abundantly decorated with paintings, one of a liturgical character. But the most extensive catacombs at Alexandria are those of Egypto-Greek origin, from the largest of which, according to Strabo (lib. xvii. p. 795), the quarter where it is placed had the name of the Necropolis. The plan is remarkable for its regularity (fig. 8). Here, too, the graves run endways into the rock. There are other catacombs in the vicinity of the same city.

Subterranean cemeteries of the general character of those described are very frequent in all southern and eastern countries. A vast necropolis in the environs of Saida, the ancient Sidon, consists of a series of apartments approached by staircases.

Recent Discoveries.—At Rome, after the death of de Rossi (1894) a small subterranean basilica in the catacomb of SS. Peter

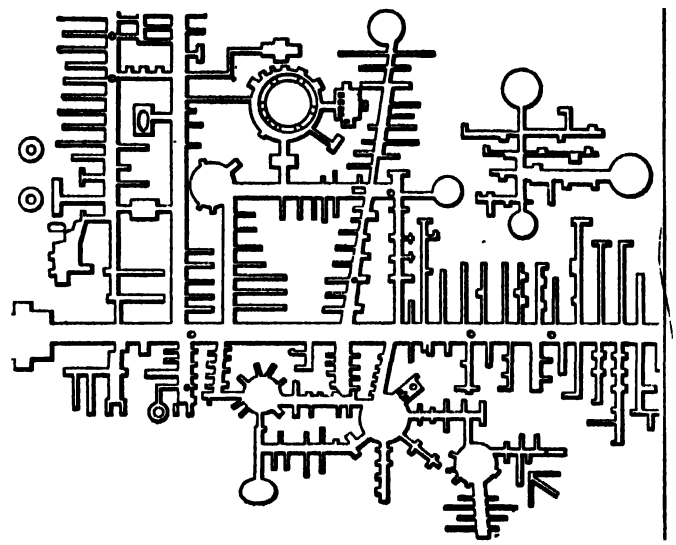

FIG. 6.—THE PLAN OF THE CATACOMB OF S. JOHN, SYRACUSE

and Marcellinus on the Via Labicana, with pious acclamations on the plaster similar to those in the Papal crypt in St. Calixtus was discovered in 1896. In the cemetery of Domitilla in 1897–1898 a fine double crypt with frescoes representing Christ seated between six male and female saints and an inscription relating to a new saint (Eulalius) in a cubiculum of the 3rd century was brought to light. In 1899–1900 were discovered two opposite cubicula in the catacomb of SS. Peter and Marcellinus, both covered with frescoes, the vault being in one case decorated with the scene which represents Christ seated among the apostles and pronouncing sentence upon the defunct. An inscription discovered in 1960 on the site of the ancient cemetery of St. Ciriaca, and dating from A.D. 405, states that one Euryalus bought a site *ad mensam beati martyris Laurentii* from a certain *fossor* whose name has been erased, an example of what was known as *memoriae damnatio*, or the blotting out of a name on account of some dishonourable action. In 1901–1902 excavations in the cemetery of Santa Priscilla, near the Cappella Greca, revealed a polygonal chamber which may have originally been the *nymphaeum* of the great villa of the Acilii Glabriones. It may have been used as a burial-place for martyrs, and as the sepulchral chapel of Pope Marcellinus, who died in A.D. 304 during the persecutions of Diocletian. In 1902, in that part of the Via Ardeatina which passes between the cemeteries of Calixtus and Domitilla, was discovered a crypt with frescoes and the sanctuary of a martyr; this, rather than a neighbouring crypt brought to light in 1897, may prove to be the sepulchral crypt of SS. Marcus and Marcellianus. In a cubiculum leading out of a gallery

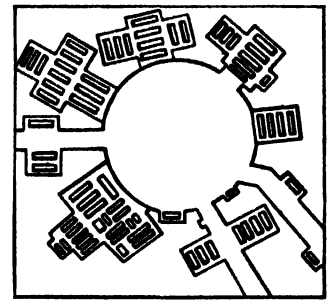

FIG. 7.—PLAN OF CIRCULAR HALL IN CATACOMBS OF S. JOHN, SYRACUSE

in the vicinity there was also discovered an interesting impression in plaster of an inscription of the mother of Pope Damasus, beginning:

Hic Damasi Mater Posvit Lavren (tia Membra).

In the same year building operations in the Via di Sant' Onofrio revealed the presence of catacombs beneath the foundations: examination of the *loculi* showed that no martyrs or illustrious

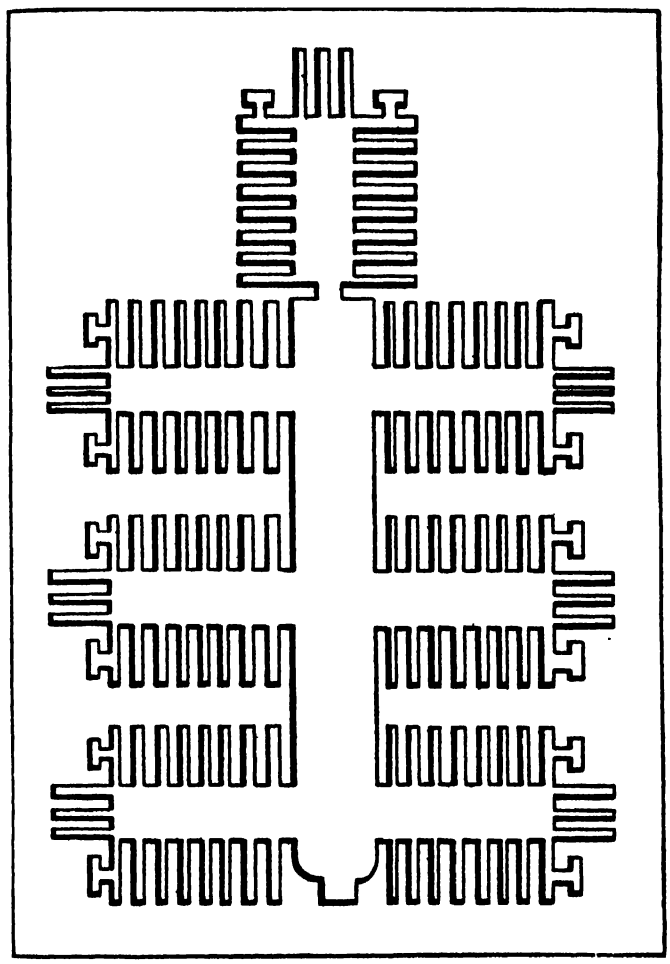

FIG. 8.—PLAN OF CATACOMB AT ALEXANDRIA

persons were buried there. Work was also carried out at the catacomb of Albano (Marucchi *Nuovo Bull.*, 1902, pp. 89 ff.).

In 1903 a new cemetery with frescoes came to light on the Via Latina, considered by Marucchi to have belonged to a heretical sect In the same year the Jewish cemetery on the Via Portuense, was rediscovered. The subterranean basilica of SS. Felix and Adauctus, discovered by Boldetti and afterwards choked up with ruins, was cleared again: the crypt, begun by Damasus and enlarged by Siricius, contains frescoes of the 6th–7th centuries. In the same year extensive catacombs were revealed on the site of Hadrumetum near Sousse in Tunisia.

In 1907–08 interesting discoveries were made in the South East of Sicily (P. Orsi, *Notizie degli Scavi*, 1908). The year 1911 witnessed the discovery of the remarkable *hypogeum* of Trebius Justus on the Via Latina, with frescoes showing gnostic influence (*Nuovo Bull.* 1911 and 1912). In 1912 a catacomb was found at Grottaferrata which has since been excavated by the Basilian monks. In 1915–1916 a *memoria* of SS. Peter and Paul was explored beneath the basilica of S. Sebastiano, *Ad catacumbas*, on the Appian way. *Graffiti* with invocations to these apostles, dating from the fourth century were discovered (Marucchi, *Nuovo Bullettino*, for 1916, 1917, 1919, 1920). In 1917 was found subterranean basilica of the first century, perhaps the work of a pagan *sodalitas* (g. Bagnani, *Journ. of Roman Studies*, 1919, p. 78). In 1919, not far from the Porta Maggiore and the ancient Via Labicana, a *hypogeum* with two frescoed chambers was discovered. The subjects were unusual; one, Christ instructing his sheep from a book recalled a passage in the inscriptions of Abercius in the Lateran; others were scenes from the story of Job diverging from those usual in the Catacombs; a group of 12 figures, perhaps apostles, including two recalling the traditional types of SS. Peter and Paul (Marucchi, *Nuovo Bull.* 1921). The year 1921 witnessed the rediscovery near the catacomb of Priscilla on the Via Salaria Nuova, of the *Coemeterium Jordanorum*, first found in 1578 but soon afterwards choked up and lost (Marucchi and Josi, *Nuovo Bull.* 1922).

BIBLIOGRAPHY.—The classical work on the catacombs of Rome is G. B. De Rossi's *Roma sotterranea*. The volume by Mgr. Wilpert, *Le Pitture delle catacombe romane* (Rome, 1903), in which all the important frescoes are reproduced in colours, is complementary to the *Roma sotterranea*. All new discoveries made by the *Commissione di archeologia sacra* are chronicled in the *Nuovo Bullettino de archeologia* the *Notizie degli scavi*.

For accounts of the catacombs *see*:—Armellini, *Gli Antichi Cimiteri cristiani di Roma e d'Italia* (Rome, 1893); O. Marucchi, *Le Catacombe romane* (Rome, 1903; also translated into French), *Manuale di epigrafia cristiana* (Milan, 1904); M. Besnier, *Les Catacombes de Rome* (Paris, 1909); F. X. Kraus (*Realencyklopädie* and *Geschichte der christlichen Kunst*) and Dom F. Cabrol's *Dictionnaire d'archéologie chrétienne et liturgie*, articles with bibliography, by H. Leclercq.

Among the older works are: Bosio, *Roma sotterranea*, Severano's edition (1632), and Aringhi's edition (1651); Boldetti, *Osservazioni sopra i cimiteri dei santi martiri* (Rome, 1720); Bottari, *Sculture e pitture sagre*, etc. (Rome, 1737–1754); Seroux d'Agincourt, *Histoire de l'art par les monuments* (Paris, 1823; German ed., 1840); G. Marchi, *Monumenti delle arti cristiane primitive* (Rome, 1844); Raoul Rochette, *Tableau des catacombes de Rome* (2nd ed., Paris, 1853); Perret, *Les Catacombes de Rome* (Paris, 1855)—a sumptuous folio work, but not always accurate; Roller, *Les Catacombes de Rome* (Paris, 1881); V. Schultze, *Die Katakomben* (Leipzig, 1882).

Works written in English are: Northcote and Brownlow, *Roma sotterranea* (London, 1869; based upon De Rossi); Wharton Marriott, *The Testimony of the Catacombs* (1870); J. H. Parker, *The Archaeology of Rome: the Catacombs;* Smith and Cheetham, *Dictionary of Christian Antiquities, s.v.* "Catacombs"; R. Lanciani, *Pagan and Christian Rome* (1892); W. Lowry, *Christian Art and Archaeology*, ch. ii. (1901; a useful introduction to the subject); H. Gee, "The Church in the Catacombs," in W. Lefroy's *Lectures in Ecclesiastical History* (1896); Th. Mommsen, in the *Contemporary Review* (May 1871).

The catacombs at Naples are described in C. F. Bellermann, *Über die ältesten christlichen Begräbnisstätten und besonders die Katakomben zu Neapel* (Hamburg, 1839); Armellini, as above and V. Schultze, *Die Katakomben von San Gennaro dei Poveri in Neapel* (Jena, 1877).

For the catacombs in Malta, A. A. Caruana, *Ancient Pagan Tombs and Christian Cemeteries in the Islands of Malta* (Malta, 1898). and A. Mayr, "Die altchristlichen Begräbnisstätten auf Malta," in *Römische Quartalschrift*, vol. xv. pp. 216 and 352 (Rome, 1901), and E. Becker, *Malta Sotterranea* (Strasbourg, 1913), may be consulted.

The fullest accounts of the Sicilian catacombs are given by J. Fuhrer, *Forschungen zur Sicilia sotterranea* (Munich, 1897); C. Barreca, *Le Catacombe di San Giovanni in Siracusa* (Syracuse, 1906); J. Fuhrer and V. Schultze, *Die altchristlichen Grabstätten Siziliens* (Berlin, 1907); and P. Orsi, *Per la Siracusa Sotterranea* (Catania, 1906).

A catacomb of the 5th century, discovered at Kertch in South Russia, is described by J. Kulakovsky in *Materials for Russian Archaeology* (St. Petersburg, 1896; a publication of the Russian Imperial Archaeological Commission), but it is written in Russian, as also is the account by V. Latyshev, in *Vizantieski Vremennik*, vol. vi. pp. 337 ff. (St. Petersburg, 1899).

The catacombs at Hadrumetum (Sousse) are described by A. F. Leynaud, *Les Catacombes d'Hadrumète, deuxième campagne de fouilles* (1904–1905). *See* also *Revue Tunisienne* (1905), p. 250.

For the catacombs of Alexandria, de Rossi in *Bull. di archeologia Cristiana* (Nov. 1864, Dec. 1865); Neroutsos Bey, *L'Ancienne Alexandrie.*

(W. R. B.; O. M. D.)

CATAFALQUE, a word of unknown origin, occurring in various forms in many European languages, meaning a funeral scaffold or temporary stage; a movable structure of wood, sometimes richly decorated, erected temporarily at funeral ceremonies in a church to receive the coffin or effigy of the deceased; also an open hearse or funeral car.

CATALAN. It is generally assumed that Catalan was imported from Roussillon into Spain during Carolingian times; the contrary view has, however, been put forward, namely that Catalan originally developed in Spain and was introduced into Cerdagne and Roussillon by Catalan immigration. Whatever the truth may be, philologically Catalan is to be regarded as pertain-

ing to the Provençal rather than to the Hispanic branch. Like Hispanic it changes L. *ū* into *u* and L. *au* into *o*, *cf.*, L. *mūrum*, Cat. *mur*, Hisp. *muro* (Prov. Fr. *mur*); L. *aurum*, Cat. and Hisp. *oro* (Prov. *aur*, Fr. *or*).

Unknown to Catalan, however, are the characteristically Hispanic diphthongizations of open *e* and open *o* in position; *cf.*, L. *terra*, Hisp. *tierra*, but Cat. *terra*; L. *fortem*, Hisp. *fuerte*, but Cat. *fort* (as in Prov. and Fr.). Moreover Catalan and Provençal both change proparoxytones into paroxytones, whereas in Hispanic the proparoxytones are preserved (*e.g.*, L. *anima*, Cat. and Prov. *alma*, *arma*).

Catalan survived in modern times in the major part of the department of the Pyrénées Orientales, in Andorra, at Alghero (Sardinia) whither it was brought by the Aragonese in the second quarter of the 14th century but where it steadily succumbed to the disruptive influence of Italian and Sardinian; in the provinces of Huesca, Saragossa, Ternel; in the greater part of the provinces of Castellon de la Plana and Alicante; in much of the province of Valencia; and in the Balearic Islands and Pithyusae, conquered by Jaime I of Aragon (1229–34).

Catalan embraces two groups, viz., (1) continental, subdivided into (*a*) oriental, (*b*) occidental, (*c*) Valencian, (*d*) Roussillonnais; (2) insular, subdivided into (*a*) dialects of the Balearic Islands and Pithyusae, (*b*) dialect of Alghero.

All these idioms present only minor phonetic differences. In the Balearic Islands *es*, *sa* constitute the definite article (as also in the subdialect of oriental Catalan termed for this reason, *salat*) instead of *el*, *la*.

The outstanding difference between the Catalan of Spain and that of Roussillon is that whereas the former is a real language with a flourishing literature the latter is a mere patois.

BIBLIOGRAPHY.—P. Fouché, *Chronique philologique des parlers provençaux anciens et modernes* (Bibl.) in *Revue de linguistique romane* T. II. (Janvier-Juin, 1926) p. 113–136; A. Griera, *Le domaine catalan (compte rendu rétrospectif jusqu'à 1924)* in *Revue de linguistique romane* T. I. (Janvier-Juin, 1925) p. 35–113. (L. B.)

CATALANI, ALFREDO (1854–1893), Italian composer, was born at Lucca, on June 19, 1854, and studied under the French composer, Emmanuel Bazin, at the Paris conservatoire and at the Milan conservatoire.

His well-known opera *La Wally*, first performed in 1892, was favourably received in Italy, and it was produced at the Metropolitan Opera house, New York city, in 1908–09. *Loreley* (Turin, 1890) was performed in Chicago, Ill., in 1918 and in New York city in 1921–22.

Catalani's other works include *La Falce*, his first dramatic work, produced in 1875; *Elda* (Turin, 1880), a four-act opera; *Dejanice* (Milan, 1883), also in four acts; *Ero e Leandro* (1885), a symphonic poem for orchestra; and *Edmea* (Milan, 1886), a three-act opera.

Catalani died in Milan on Aug. 7, 1893.

CATALANI, ANGELICA (1780–1849), Italian opera singer, was born at Sinigaglia, on May 10, 1780, and was the lucky possessor of one of the most remarkable soprano voices, of extraordinary compass and purity, ever known.

For nearly 30 years she sang at all the great opera houses, receiving very large fees.

At an early age she entered the Santa Lucia convent at Gubbio. After leaving the convent she had very successful engagements throughout Italy, first appearing in Venice at the age of 16.

She appeared at the Italian opera in Portugal in 1804 and later sang in Madrid and Paris, her reputation continuing to increase wherever she sang.

Her first appearance in London was at the King's theatre in 1806. She remained in England, a prima donna without a serious rival, for seven years.

Then she was given the management of the opera in Paris, but this resulted in financial failure because of the incapacity and extravagance of her husband, Captain Valabrègue—author of the historic remark, "ma femme et quatre ou cinq poupées voila tout ce qu'il faut"—whom she had married in 1806.

But her continental tours continued to be enormously successful until she retired in 1828.

She died of cholera in Paris on June 12, 1849.

CATALINA ISLAND: *see* SANTA CATALINA.

CATALOGUE, a list or enumeration, generally in alphabetical order, of persons, things, etc., and particularly of the contents of a museum or library.

A *catalogue raisonnée* is such a list classified according to subjects or on some other basis, usually with short explanations and notes.

(*See* also BIBLIOGRAPHY; LIBRARIES.)

CATALOGUES AND PRICE LISTS. The preparation and distribution of catalogues and price lists has become an industry of enormous dimensions, the cost of printing and publishing amounting to millions of pounds a year in Great Britain alone, while the expenditure of this sort in the United States also amounts to many millions of dollars each year.

It was increasingly recognized that an attractive catalogue, distributed in the right way, is one of the best aids to salesmanship. The cost of production of fifty or a hundred thousand catalogues of moderate size amounts to an extremely serious item in business expenditure.

In not a few instances this leads to the cutting down of expense upon the preparation of the catalogue, and this is undoubtedly the chief weakness in the preparation of commercial price lists. Another reason for the failure of many expensive catalogues is that the publisher may forget that, although he may be successful in manufacturing a certain article, it does not necessarily follow that he is successful in describing his product for catalogue purposes.

It is very important, therefore, that efficient literary aid should be called in by the business man to make his catalogues lucid. Thus, also, with any necessary pictures.

Often the printing blocks in an expensive production have little artistic merit, and do not do full justice to the products. If we suppose ten thousand pounds to be spent upon a catalogue issue, the value of the expenditure may easily be doubled or trebled by spending an additional two hundred pounds upon the editorial work.

It is not difficult for the business man to forget in preparing a catalogue that those he wishes to read it are not as familiar with his productions as he is himself. Simplicity and lucidity of description are essential, and in this connection care should be taken to avoid the listing of a complexity of types. The excellent work done by the Washington Department of Commerce in reducing the number of types of products in various trades is directed to what is really the same point. Variety, of course, there should be, but the types chosen for listing should be distinctly different, and the reasons for the differences very clearly stated.

If, for example, the catalogue offers a series of gas heaters and cookers, the types chosen should not only be essentially different, but the essential differences should be made quite clear to the reader. If the stove is a heating appliance, the kind of room for which it is suited, the kind of flue needed, the method of installation, and the cost of maintenance should all be demonstrated. When prices vary in a series, the reason for the differences should appear. Nothing is more confusing or stultifying in a catalogue than to be told on one page that Type A of a certain manufacture is the "best," or the "finest," when the very next page refers to another thing of the same sort priced at a much higher figure. What should be done is to show clearly that the article priced is good value at its price; good value for its particular purpose; good value to meet a particular need.

The Listing of "Extras."—Every endeavour should be made in drawing up a catalogue to offer each article ready for use, at a price covering the entire equipment necessary to put it into use. Thus, at one time it was the unfortunate practice of motor-car manufacturers to offer their machines at a certain price, and then to add a long list of extras necessary to fit out the machine ready for the road. This practice has, happily, been abandoned in the automobile industry, but it still obtains in many other trades. First, the buyer is offered the article at a certain price, but this price does not represent the thing ready for use or consumption; a number of extras are listed in a confusing way so that the real

price of the article fit for use has to be worked out with more or less difficulty. The manufacturer of a machine-tool gains when he offers his product completely fitted with necessary safety-appliances; equally the manufacturer of a roofing felt is likely to increase his sales if his price list shows the material put into convenient rolls well packed, accompanied with the necessary amount of cement for the lapping of edges, and with purpose-made nails to fix it. The aim of every catalogue should be to offer the articles it lists ready for use.

The format of a catalogue is of great importance. The catalogue of a store should be divided into sections and well indexed. In the case of the small catalogue, or "folder," it is far better to concentrate upon one really good production at a time than to issue a sheaf of documents of different sizes which are only too likely to bewilder and irritate the would-be buyer. It is quite usual at trade exhibitions to be handed half a dozen differently shaped folders referring to a single object, instead of being given one handy, pocket-sized, beautifully printed, well-considered piece of printing.

An excellent aid to business in a catalogue, and one that is much appreciated by buyers, is the insertion of intelligent matter directly or indirectly relating to the articles offered. This may be illustrated by the case of a sports catalogue. The manufacturer of cricket-bats or tennis-rackets does well to include in his catalogue expert directions for the preservation of the articles sold, or hints on the laws of the game, or other interesting cognate matter. Again, the catalogue of a piano-player may well be accompanied by a lucid account of the invention, instructions for the care of the instrument, hints as to getting the best results from it, and so forth.

As to catalogues for the export market, it is an old complaint, and a just one, that their publishers too often fail to adapt them to the needs of the country to which they are supposed to appeal. If a catalogue is prepared for South America, for example, it is quite useless to prepare it in English; it should be translated into Spanish (or into Portuguese, if for Brazil) and weights and measures and prices expressed in their proper equivalents. Consular reports from foreign countries again and again dwell upon the neglect of these elementary measures for making an export catalogue useful.

CATALONIA (*Cataluña*), an autonomous region, and formerly a province of Spain, formerly also a principality of Aragon; bounded on the north by the Pyrenees, west by Aragon, south by Valencia, and east by the Mediterranean Sea. Population (1950) 3,240,313; area, 12,414 sq. miles. The triangular territory of Catalonia forms the north-east corner of the Iberian Peninsula. It was divided in 1833 into four provinces, Barcelona, Gerona, Lérida and Tarragona (*see* separate articles). The surface is much broken by southern spurs of the Pyrenees. Running south-west to north-east, and united on the north with one of the offsets of the Pyrenees, is the range of the Sierra Llena, which bisects Catalonia, and forms its central watershed. The principal rivers are the Ter, the Llobrégat and the Ebro (*q.v.*), which all run into the Mediterranean. The coast is in places difficult but has important harbours, *e.g.*, Barcelona and Tarragona. Cut off orographically on the south and west Catalonia has had more associations with south France than with the Douro or Guadalquivir basins, and the Catalan language differs considerably from Castilian Spanish and has affinities with Provençal. Catalonia was one of the first of the Roman possessions in Spain, forming the north-eastern portion of Hispania Tarraconensis. About 470 it was occupied by Alans and Goths. It was conquered by the Moors in 712, but these invaders were in turn dispossessed by the Spaniards and the troops of Charlemagne in 788. Catalonia was subsequently ruled by French counts, who soon made themselves independent of France. By the marriage of Count Raymond Berenger IV. of Barcelona with Petronilla of Aragon, Catalonia became annexed to Aragon but this union was frequently severed. In 1640, when Philip IV. attempted to deprive Catalonia of its rights and privileges, it gave itself up to Louis XIII. of France. It was restored to Spain in 1659, and was once more occupied by the French from 1694 to 1697. Under Philip V. Catalonia, in 1714, was deprived of its cortes and liberties. From 1808 to 1813 it was held by France. It was the scene of civil war in 1823, and of revolutionary operations in the Carlist wars. It supported the Loyalist cause in 1936–39. *See* also SPAIN and BARCELONA.

The average yearly temperature varies from 48° to 75°; the rainfall is about 21 in. with a maximum in the early fall months and a lower maximum in the spring. The dwarf-palm, orange, lime and olive grow in the warmer tracts; and on the higher grounds the thorn-apple, pomegranate, myrtle, esparto and heaths flourish. There is much woodland, but meadows and pastures are rare. Wheat, maize, millet, rye, flax, liquorice, vines and fruits of all sorts—especially nuts, almonds, oranges, figs and walnuts and chestnuts—are produced. Few cattle, but numbers of sheep, goats and swine are reared. Coastal fisheries are excellent. The wines are for the most part rough and strong, though good when matured. Catalonia was prominent in the wool industry early in the Middle Ages, and in modern times the extended use of water-power for textile manufacture made Barcelona an important industrial and commercial city. With the increase of irrigation the country around the city was developed as a wheat growing area.

CATALPA, a genus of trees belonging to the family Bignoniaceae and containing about 10 species in North America, the West Indies and China. The best known is the common catalpa (*C. bignonioides*), native to the southeastern United States, but often cultivated in parks and gardens, both in Europe and America. It is a stately tree with large, heart-shaped, pointed leaves and panicles of white, bell-shaped flowers streaked with yellow and brown-purple. The hardy catalpa (*C. speciosa*), with larger flowers, found in woods from Indiana to Missouri southward to Tennessee and Arkansas, has become naturalized elsewhere through cultivation, especially south of its native range.

CATALYSIS. Classically, the word catalysis means dissolution, destruction or ruin. J. J. Berzelius retained this meaning when, in 1836, he first applied the term to chemical reactions. He used it to describe the chemical decomposition of a substance hastened by a second substance (a catalyst) which did not enter into the composition of the product formed. With use, the original meaning of catalysis was lost. The term was applied to synthesis (constructive) as well as decomposition (destructive) reactions which are accelerated by a substance (the catalyst) not permanently changed in the process. Since the catalyst is not permanently changed, it may be used over and over again. A small amount of catalyst can thus effect the conversion of a large amount of the substance being changed. It is this property of catalysts which makes them so useful.

Catalysts may be gases, liquids and solids. They exert their catalytic effects on gases, liquids and solids to produce gases, liquids and solids. Although a few catalysts had been predicted for certain reactions, the science in mid-20th century had not progressed to the point where it was possible to predict generally a catalyst for a desired reaction. Catalysts for one reaction are often worthless for other reactions. Thus, catalysis bears some of the aspects of an art rather than a science in spite of the many facts known about catalysts and catalytic reactions.

PRACTICAL APPLICATIONS

Catalysis is of great social as well as technical and scientific importance. The average man rarely comes directly in contact with industrial catalysts and, therefore, does not realize what they do for him and how they affect the course of his life or even his death. The part played by catalysts in the production of fixed nitrogen (*see* NITROGEN, FIXATION OF) is a good example of such effects.

Fixed nitrogen is one of the essential ingredients of plant food and explosives. It is used in the form of ammonia (*q.v.*) or its derivatives, or as nitrates (*see* NITRIC ACID). Up until about 1915, fixed nitrogen was obtained from Chilean saltpetre, from a few saltpetre mines, from animal wastes and as a by-product of the coking of coal. At about this time, Fritz Haber and his co-workers produced synthetic ammonia by heating nitrogen and hydrogen, under high pressure, with a solid catalyst. Many different catalysts have been used. The early ones were osmium and ruthe-

nium. These were expensive, and so cheaper catalysts were sought and found. Commercial plants employing this process have been installed in every industrial nation in the world.

Another catalytic reaction serves to complement the above reaction. Fixed nitrogen is needed in the form of nitrates as well as in the form of ammonia. Platinum catalysts were developed which catalyze the reaction between ammonia and the oxygen of the air, to form nitrogen dioxide which with water produces nitric acid. The over-all result is a high yield of nitric acid from the catalytic oxidation of ammonia.

These two catalytic reactions have made every nation independent, or potentially independent, of Chilean nitrate or other natural nitrate deposits. The result has been a decline in the price of fixed nitrogen, an increase in consumption and healthier plants for the farmer with better and more economical food for the average man.

These two catalytic reactions also have their sinister aspects, for, until the advent of the atomic bomb, fixed nitrogen was the backbone of both explosives (*q.v.*) and propellents. Thus, much of the destruction of World War I and World War II can be associated with these catalytic reactions, for the wars would have been quite different if both sides had had to depend on Chilean nitrates for their explosives.

Motor Fuels.—Aside from its application in the fixation of nitrogen, catalysis has other important social implications. A large part, if not most, of the aviation gasoline used by all nations taking part in World War II was made with the aid of catalysts. In the United States, the catalysts were used primarily for the conversion of petroleum (*q.v.*) into hydrocarbons of good antiknock quality. (1) Petroleum oils were catalytically cracked by means of synthetic silica-alumina or acid-treated clay (montmorillonite) catalysts. This process produced the "base" for the aviation gasoline, and it was responsible for a major part of the aviation gasoline produced. (2) Branched-chain paraffin hydrocarbons were synthesized by the so-called alkylation process, using sulphuric or hydrofluoric acid catalysts. Usually, isobutane and mixed butylenes were the raw materials for the process. These were produced by the catalytic as well as the thermal cracking of petroleum. The branched-chain paraffinic product was blended with the "base" from catalytic cracking. (3) Catalytic isomerization of paraffins was used to convert n-butane into isobutane and n-pentane into isopentane. Anhydrous aluminum chloride provided the essential catalytic material for all the commercial paraffin-isomerization processes. (4) Isopropylbenzene was produced from benzene and propylene by means of phosphoric acid catalysts. The isopropylbenzene was added to the gasoline to give extra power under take-off or combat conditions where fuel economy was not a consideration. The British catalytically produced *tert.*-butylbenzene from benzene and isobutylene and used it for similar purposes. (5) Propylene and butylene (*see* OLEFINE) were catalytically polymerized with the use of phosphoric and sulphuric acid catalysts (*see* POLYMERIZATION). The product was a mixture of branched-chain octenes. These were catalytically hydrogenated, with nickel or molybdenum catalysts to produce branched-chain octanes (*see* PARAFFIN HYDROCARBONS, CHEMISTRY OF) which were used in the same way alkylate was used. (6) Straight-run gasoline was converted to material suitable for use as aviation "base" by the hydroforming process. The major use of this process during World War II, however, was to produce synthetic toluene for manufacture of T.N.T. During the postwar period, vastly superior processes of this general type came into wide use for manufacture of motor gasoline and of synthetic benzene, toluene and xylenes.

The Germans, the Japanese and, to a certain extent, the British used catalytic processes to produce aviation fuels from coal. Two major processes were used. (1) A part of the coal was converted by means of heat, steam and catalysts into hydrogen. The hydrogen was caused to react catalytically with more of the coal at high pressures (*see* HYDROGENATION; PRESSURE CHEMISTRY) to produce liquid hydrocarbons which were used directly or further processed. (2) By means of heat, steam and catalysts, the coal was converted into a mixture of carbon monoxide and hydrogen. These were used in the Fischer-Tropsch process, with catalysts containing nickel or cobalt, to produce synthetic hydrocarbons. Since these hydrocarbons were mostly of the straight-chain variety, they had poor antiknock properties and required further treatment to make good aviation fuel. These Fischer-Tropsch processes also produced diesel fuels of excellent quality, waxes and raw materials for synthetic fats and soaps.

Other Applications.—Catalysts also play their subtle but essential role in the production of synthetic rubber. Most of the synthetic rubber produced in the United States has been made from butadiene (*q.v.*) and styrene which are produced with the use of the proper catalysts.

Sulphuric acid (*q.v.*), itself a catalyst for many reactions, is produced in huge quantities with the aid of vanadium oxide catalysts which serve in the oxidation of sulphur dioxide to sulphur trioxide.

Vanadium oxides, usually in combination with silver, are also used in the oxidation of naphthalene by air to phthalic anhydride (*q.v.*). The public sees phthalic anhydride only after it has been transformed by the chemist into synthetic resins (*q.v.*) or into synthetic dyestuffs (*see* DYES, SYNTHETIC).

Methyl alcohol is produced from carbon monoxide and hydrogen. Zinc oxide-chromium oxide combinations are catalysts for this process. By the addition of potassium carbonate to the catalyst, n-propyl, isobutyl and higher alcohols are also produced. By means of a copper catalyst, methyl alcohol is converted into formaldehyde. Formaldehyde reaches the public as such or after it has been converted into synthetic resins, such as the phenol-formaldehyde and urea-formaldehyde plastics.

Even our food has felt the influence of catalysts. A considerable portion of the solid fats used for shortening or for making margarine have been produced by the catalytic hydrogenation of oils with nickel as the catalyst. The catalyst is removed completely before the product is marketed. (*See* OILS, FATS AND WAXES.)

BIOCATALYSIS

Some of the most selective catalysts known, namely the enzymes (*q.v.*) occur in nature. Each enzyme usually has a single function and will not act as a catalyst in any other way. In digestive processes, for example, a number of catalytic reactions utilize this selective action of enzymes to convert food into the forms needed for use by the body.

It is entirely possible that some if not all of the vitamins (*q.v.*) and hormones (*q.v.*) are catalysts. They have the selective action that characterizes catalysts and, in most cases, a very small amount of substance can produce large effects.

FUNCTIONS OF CATALYSTS

A catalyst can increase the rate of a reaction but it cannot change the position of the final equilibrium reached in a true equilibrium reaction. In a simple reaction such as

$$SO_2 + \tfrac{1}{2}O_2 \longrightarrow SO_3$$

the catalyst merely hastens the reaction toward equilibrium. Reactions involving organic compounds may be more complicated in that several reactions are possible. Some catalysts are selective in that they can hasten one of the possible reactions toward equilibrium leaving the other possible reactions practically unaffected. For example, two common reactions of ethyl alcohol are:

$$C_2H_5OH \cdot \rightarrow C_2H_4 + H_2O$$
$$C_2H_5OH \cdot \rightarrow CH_3CHO + H_2.$$

The first one is catalyzed by gamma alumina, the second by copper, each to the practical exclusion of the other. In the absence of catalysts both reactions occur simultaneously but at a higher temperature than the catalytic reactions. It is the ability of catalysts to accelerate selectively one of several possible reactions which made catalysis so important in industrial organic chemistry.

THEORY

Catalysis may be divided into two broad branches depending on relations between the catalyst and the materials involved in the catalytic reaction. The branches are homogeneous catalysis and

heterogeneous catalysis. In homogeneous catalysis there are no phase boundaries between the substances taking part in the reaction and the catalyst. Thus all reactions which involve only gases and which are catalyzed by a gaseous catalyst are homogeneous. The same is true for reactions involving mutually soluble liquids or dissolved solids when the catalyst is soluble in the mixture.

In heterogeneous catalysis there is a phase boundary between the catalyst and the substances reacting. The most common heterogeneous reactions are those involving solid catalysts with liquid or gaseous reactants.

Homogeneous Catalysis.—Suppose that a chemical reaction is occurring in the gaseous state, uninfluenced by the walls of the vessel. Suppose that an observer could follow the movement of all the individual atoms. He would notice persistent groupings of atoms (molecules) which move at velocities of the order of 1,000 m.p.h., colliding frequently with other molecules and emerging from the collision substantially unchanged. He would also notice that there are occasional collisions from which new molecules emerge, and perhaps that molecules occasionally fall apart in the absence of collisions. These events are called elementary reactions. (*See* REACTION KINETICS.) Types of elementary reactions include

$$\begin{aligned} A + B &\longrightarrow C + D && \text{(I)} \\ A + B &\longrightarrow A + C && \text{(II)} \\ A + B &\longrightarrow C && \text{(III)} \\ A &\longrightarrow B + C && \text{(IV)} \\ A + B + C &\longrightarrow A + D && \text{(V)} \end{aligned}$$

It seemed reasonably certain in the 1950s that reactions of all these types actually occurred. Depending upon the reaction under study, the observer might note that only a single elementary reaction was occurring, or a number of different elementary reactions.

Such direct and detailed observations, of course, cannot be made. The objectives of reaction-rate theory, however, are to determine from the observable data what elementary reactions actually occur and what their rates are, and to interpret these rates in terms of interatomic forces and atomic dynamics.

Of the above elementary reactions, Types II and V are inherently catalytic reactions, since A emerges unchanged. Type V corresponds to the combination of free atoms, or simple radicals such as OH. In such cases, conservation of energy and momentum make it impossible for combination to occur without a third body to remove some of the energy. There is little specificity in the effectiveness of various third bodies, and Type V is a trivial and uninteresting example of catalysis. Likewise in the case of Type II, the examples known at mid-century were few and unimportant.

The noncatalytic reactions of Types I, III and IV may combine in many ways to produce a total reaction that represents catalysis. A simple illustration utilizing Type I reactions is

$$\begin{aligned} A + B &\longrightarrow C + D \\ C + E &\longrightarrow B + F \end{aligned}$$

giving as the ultimate result

$$A + E \longrightarrow D + F$$

catalyzed by B (or C). A specific example is

$$\begin{aligned} O_3 + ClO_2 &\longrightarrow ClO_3 + O_2 \\ ClO_3 + O_3 &\longrightarrow ClO_2 + 2O_2 \\ \hline 2O_3 &\longrightarrow 3O_2 \end{aligned}$$

where the chlorine oxides are catalysts. In any complex mechanism of this character, it is more or less a matter of accident that the catalyst is regenerated. For this reason, there is little basis for distinguishing the theory of homogeneous gas phase catalysis from that of homogeneous gaseous reactions generally.

In solution, acids and bases are powerful catalysts for a wide variety of organic reactions. This special branch of the subject, in fact, has absorbed a predominant part of all the modern scientific work on homogeneous catalysis. The original concept of acid and base catalysis was that the effective catalysts were the hydrogen and hydroxyl ions. There are a number of important reactions, such as the hydrolysis of esters and the inversion of sucrose where the data available at mid-century were explicable on this basis. In general, however, it is necessary to invoke the modern definition of an acid (*see* ACIDS AND BASES) as a substance tending to lose a proton, and a base as one tending to gain a proton, and to recognize that all acids and bases may have catalytic activity.

The velocities of acid-base catalyzed reactions are strongly affected by the presence of neutral salts. It is customary to distinguish primary and secondary salt effects. The secondary salt effect occurs only in catalysis by weak electrolytes, and is caused by increased dissociation of the weak electrolyte caused by the presence of the neutral salt. This effect is purely thermodynamic in origin, and for sufficiently dilute solutions may be quantitatively predicted by the Debye-Hückel theory.

The primary salt effect, on the other hand, occurs with all acid-base catalysts of whatever strength. It is specific to the reaction, the catalyst and the added salt. The primary salt effect is usually positive (increase in reaction rate due to salt) but for basic catalysts is sometimes negative. The explanation current at mid-20th century for the primary salt effect is based on J. N. Bronsted's equation

$$k = k_0 \frac{f_A f_B}{f_X}$$

for the reaction rate constant k for the reaction

$$A + B \longrightarrow C + D$$

where f_A, f_B and f_X are the activity coefficients for A, B, and X, the assumed "critical complex" or intermediate compound, and k_0 is a constant. If this equation be granted, the calculation of primary salt effects then becomes a thermodynamic problem. Since definite information as to the critical complex, X, is limited to knowledge of its charge, this thermodynamic problem can be treated only approximately. The results, however, are consistent with experimental data on the primary salt effect.

The general picture of acid-base catalysis, from the standpoint of physical chemistry, is that the catalyst converts the reactant molecule to an ion by proton exchange, and that the ion then reacts. The interest of the organic chemist in the same phenomenon is largely that of interpreting the nature of the subsequent reactions. It is impossible to discuss the details here but it may be mentioned that reactions subject to acid-base catalysis include esterification, bromination, isomerization, molecular rearrangements, dehydration, alkylation and polymerization.

Heterogeneous Catalysis.—The best established examples of heterogeneous catalysis involve solid catalysts and liquid or gaseous reactants. It is almost universally true that massive materials have little or no catalytic activity, and that active catalysts are highly porous, and have total surface areas of 50-500 sq.mi./g. (5-50 ac./lb.).

There have been various theories with regard to the general nature of heterogeneous catalysis. In mid-20th century, however, there were few dissenters from the view that it involves a sequence of reactions in which the catalyst surface participates as an actual chemical reactant. The question whether the entire surface participates, or only a relatively few "active centres" such as edge or corner atoms in crystals, was in dispute.

Study of the adsorption of gases on catalyst surfaces reveals two types of adsorption (*q.v.*). The first type of adsorption is called physical or van der Waals' adsorption, since it is believed to be caused by intermolecular forces which do not disturb the existing valence bonds. The second type is called activated adsorption or chemisorption, since it is believed to represent the creation of new valence bonds. With few exceptions, heterogeneous catalysis depends on activated adsorption.

The rate of every heterogeneous reaction, therefore, depends in principle upon rates of adsorption, reaction and desorption. By reaction kinetic treatment of particular mechanisms it is possible to reproduce the major features of experimental rate data, namely that the reaction order is usually low and that retardation not only by the products but by some of the reactants is frequent. The quantitative value of such kinetic treatments is impaired by the practical necessity of using oversimplified models.

Negative Catalysis.—This term has been frequently, and rather loosely, applied to factors which decrease the rate of a reaction. On thermodynamic grounds a negative catalyst cannot produce an independently occurring reverse reaction. By definition, a negative catalyst cannot affect the reaction rate constant of any true elementary reaction. The only thing a negative catalyst can do, therefore, is to introduce additional elementary reactions, which may result in a lowered over-all reaction rate. This may be done either by stopping a reaction chain, or by destroying a catalyst. The latter effect is usually referred to as poisoning. Poisoning may be either permanent or temporary. From the practical standpoint, poisoning is usually objectionable, although there are a few cases in which selective poisoning is put to practical use. Substances which retard reactions by breaking chains are frequently called inhibitors. They are of major importance in preventing deterioration of gasoline, lubricants, rubber, fats, oils and other important commercial products. (*See* ANTIOXIDANTS.)

TECHNIQUE OF CATALYSIS

An outstanding feature of catalysis is the fact that chemical composition alone does not provide an adequate description of a catalyst. It has been seen that a large surface area is generally essential. It is common practice to use an inert material of large surface area as a "support" or "carrier." The active catalyst may be deposited on the support by chemical means. Commonly used supports include activated carbon, diatomaceous earth, pumice, silica gel and alumina. The use of supports is advantageous in some cases because a costly catalyst material such as platinum or silver is used more economically, and in other cases because greater stability is conferred on the catalyst.

Whether supports are used or not, the details of catalyst preparation exert major effects on the properties of the finished catalyst. Some of these effects may be correlated with such properties as crystal structure, crystal size, surface area and residual impurities, but many of them are as yet unexplained.

In many cases a catalyst can be improved by the addition of minor amounts of an additional component, which is not a catalyst by itself. Such a substance is called a "promoter." Sometimes a second promoter will still further enhance catalytic activity. In other cases a mixture of two catalytic materials will be more active than either alone; this effect is called "synergism." In still other cases a catalyst may be composed of two materials neither of which is active alone. Thus a catalyst composed of two materials may be a true two-component catalyst or a supported catalyst, or it may involve promotion or synergism.

It is possible to summarize only a few of the heterogeneous catalysts which have proved useful. For hydrogenations catalysts involving metallic nickel, iron, cobalt, platinum, palladium or copper, the oxides of copper, zinc or chromium, and the sulphides of molybdenum are common. For dehydrogenations the catalysts may involve: copper, platinum or palladium as metals, aluminum, magnesium, zinc, chromium and molybdenum as oxygen compounds, and nickel, molybdenum and tungsten as sulphur compounds. For oxidations the catalysts may involve: platinum and silver as metals, and vanadium, silver, copper and chromium as oxygen compounds. For dehydrations gamma alumina is by far the most largely used catalyst. Finally there is a group of apparently dissimilar "acid-acting" catalysts for Friedel-Crafts reactions and other reactions which involve carbonium ions. This group includes anhydrous aluminum chloride and bromide, boron fluoride, concentrated sulphuric and phosphoric acids, anhydrous hydrogen fluoride, and the silica-alumina type of catalyst used for catalytic cracking.

All known heterogeneous catalysts deteriorate with use. A common and perhaps universal cause of deterioration is loss of surface area by recrystallization. In some cases there is also an actual change in crystal type, such as from gamma alumina to alpha alumina. In addition, most catalysts are subject to "poisoning." Poisons are classed as temporary and permanent. Temporary poisons are adsorbed relatively weakly at reaction conditions, and these effects disappear more or less rapidly when the poisons are no longer present in the stream flowing to the catalyst. Permanent poisons are more strongly adsorbed, and their effects are not merely transient. Sulphur is a particularly common permanent poison for many metallic catalysts. An important "permanent" poison in some hydrocarbon reactions is a carbonaceous material of high molecular weight and of relatively low hydrogen content, which is formed as a minor reaction product. This material is produced in many high-temperature reactions, such as catalytic cracking and dehydrogenation. It is common industrial practice to "regenerate" the catalyst periodically by burning this "coke" under suitably controlled conditions. (C. L. T.; L. S. KL.)

CATAMARAN: *see* SHIP.

CATAMARCA, an Andean province of the Argentine republic, lying between 26° and 30° S. latitude and 65° and 69° 30′ W. longitude. It is bounded on the north by the province of Salta, east by the provinces of Tucumán and Santiago del Estero, south by the provinces of Córdoba and La Rioja and west by Chile, from which it is separated by the cordillera of the Andes. The area of Catamarca is approximately 45,829 sq.mi. Population (1947) 147,213. The chief city of the province is Catamarca (pop. [1947] 31,067), the capital, situated on a fertile tableland in the southeastern part of the province. Other important cities are Andalgalá, Tinogasta and Belén.

The region is in general mountainous, with many high peaks perpetually covered by snow. Between the numerous longitudinal ranges of mountains are tablelands and valleys, some of the latter being exceedingly fertile while others are completely barren and covered by sand. The climate varies with altitude but is for the most part warm and dry, the rainfall ranging from 8 to 15 in. in the west to 24 in. in the east. Water is one of the major problems in the province, and its scarcity greatly retarded the development of agriculture and grazing. The principal crops sown are alfalfa, maize and wheat. The principal minerals of the province that are exploited are wolfram, copper, mica, antimony, clay, asbestos and tin. Of these, and in direct response to markets created by World War II, wolfram and mica came to rank first in economic importance. Another industry that characterizes the region, carried on largely by women, is the hand weaving of fine ponchos and cloth from wool and vicuña. Olives are grown extensively.

Two railways, the former Central Córdoba and the Central Norte Argentino, merged in the national railway system, serve the southeastern part of the province. The latter line provides direct communication between the capital of the province and the federal capital, a distance of 895 mi. Highways are mostly in the eastern half of the province. (R. W. RD.; C. E. MC.)

CATAMARCA (*San Fernando de Catamarca*), capital of province of same name on Río del Valle de Catamarca, Argentina, 230 mi. (318 mi. by rail) N.N.W. of Córdoba. Pop. (1947 census) 31,067. The city stands in a narrow, picturesque valley at the foot of the Sierra de Ambato, 1,772 ft. above sea level. The valley is highly fertile, partially wooded, and produces fruit in abundance, wine and some cereals. In the city are flour mills and tanneries, and among its exports are leather, fruit, wine, flour and a curious embroidery for which the women of Catamarca have long been famous. There are several fine churches, which have been declared national monuments. The alameda is one of the most attractive in the Argentine republic, having a reservoir of 2 ac. surrounded by shrubbery and walks. Catamarca was founded in 1683 by Fernando de Mendoza because the town of Chacra, the former provincial capital had been found unhealthful. Previous to the selection of Chacra as the provincial capital, the seat of government was at San Juan de la Rivera de Londres, founded in 1558 and named after the capital of England by order of Philip II in honour of his marriage with Queen Mary. Catamara is one of the communities of the republic which most conserves the traditional spirit of the colonial and postindependence eras. (C. E. Mc.)

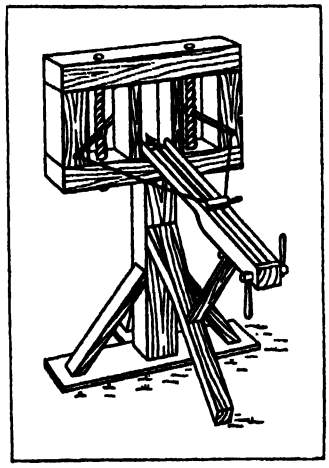
CATANIA, a city and episcopal see of Sicily, the chief town of the province of Catania, on the east coast, 59 mi. S. of Messina by rail and 151 mi. S.E. of Palermo by rail (102 mi. direct). Pop. (1951) 297,531 (commune). The cathedral of S. Agatha, with relics of the saint, retains its three original Norman apses (1091), but is otherwise baroque and there are other good baroque churches and palaces. In the west the huge Benedictine abbey of S. Nicola (now suppressed) occupies about 21 ac. and contains the museum, a library, observatory, etc. This was the highest point of the ancient city, which lay almost entirely to the west of the modern Via Stesicorea Etuca, which runs for 3,000 yd. in a straight line toward the summit of Mt. Etna. The university, founded in 1444, has regained some of its former importance. To the south near the harbour is the massive Castel

Ursino, erected in 1232 by Frederick II. The Roman theatre (no Greek theatre has been found) has been superimposed upon the Greek building, some foundations of which, in calcareous stone, of which the seats are also made, still exist. It is 106 yd. in diameter, and is estimated to have accommodated 7,000 spectators. Close to it are the remains of the so-called Odeum, of similar plan to the theatre but without a stage, and to the north is the church of S. Maria Rotonda, originally a Roman domed structure, perhaps part of a bath. To the north, in the Piazza Stesicoro, is the amphitheatre, a considerable portion of which has been uncovered, including a part of the arcades of the exterior already excavated. The external diameters of the amphitheatre are 410 and 348 ft., while the corresponding diameters of the arena are 233 and 167 ft. It is thus the third largest Roman amphitheatre known, being surpassed only by that at Verona and the Colosseum. Remains of many other Roman buildings also exist beneath the modern town, among the best preserved of which may be noted the public baths (*Thermae Achilleae*) under the cathedral, and those under the church of S. Maria dell' Indirizzo. The number of baths is remarkable, and gives some idea of the luxury of the place in Roman times. The majority were excavated by Prince Ignazio Biscari (1719–86). Some monumental Roman tombs have also been found, and it is only from their position that we can infer the boundaries of the Roman city, for no remains of its walls exist.

Catania exports sulphur, pumice stone, asphalt, oranges and lemons, almonds, filberts, cereals, wine and oil. The harbour is a good one. There is an old harbour with an area of .03 sq.mi. and a new harbour of .16 sq. mi.; the combined length of quays is 2 mi. Sulphide of carbon is produced here; and there are large dyeworks.

The ancient Catina (Gr. *Katane*, Rom. *Catina*[1]) was founded in 729 B.C. by colonists from Naxos, perhaps on the site of an earlier Sicel settlement—the name is entirely un-Greek, and may be derived from *κάτινον*, which in the Sicel language, as *catinum* in Latin, meant a basin, and would thus describe the situation. Charondas, a citizen of Catina, is famous as its lawgiver, but his date and birthplace are alike uncertain; the fragments preserved of his laws show that they belong to a somewhat primitive period. The poet Stesichorus of Himera died here. Very little is heard of Catina in history until 476 B.C., when Hiero I. removed its inhabitants to Leontini, repeopled it with 5,000 Syracusans and 5,000 Peloponnesians, and changed its name to Aetna. In 461 B.C., however, with the help of Ducetius and the Syracusans, the former inhabitants recovered possession of their city and revived the old name. Catina was, however, an ally of Athens during the Syracusan expedition (415–413 B.C.), and served as the Athenian base of operations in the early part of the war. In 403 B.C. it was taken by Dionysius of Syracuse, who plundered the city, sold the inhabitants into slavery and replaced them with Campanian mercenaries. In the First Punic War it was one of the first cities of Sicily to be taken by the Romans (263 B.C.). In 123 B.C. there was an eruption of Etna so violent that the tithe on the territory of Catina payable to Rome was remitted for ten years. It appears to have flourished in the first century B.C., but to have suffered from the ravages of Sextus Pompeius. It became a Roman colony under Augustus, and it is from this period that the fertile plain, hitherto called the plain of Leontini, begins to be called the plain of Catina. It seems to have been at this time the most important city in the island, to judge from the language of Strabo and the number of inscriptions found there. In A.D. 251 a lava stream threatened the town and entered the amphitheatre, which in the time of Theodoric had fallen into ruins, as is clear from the fact that he permitted the use of its fallen stones for new buildings. It was occupied by Belisarius in 546, sacked by the Saracens in 902 and taken by the Normans. The latter founded the cathedral; but the town was almost entirely destroyed by earthquake in 1170, and devastated by Henry VI. in 1197. It became the usual residence of the Aragonese viceroys of the 13th and 14th centuries, and one of them, De Vego, reconstructed the fortifications in 1552. In 1669 an eruption of Etna partly filled up the harbour, but spared the town, which was, however, almost entirely destroyed by the earthquake of 1693. During World War II Catania was heavily bombed by Allied planes. Near Catania the Germans put up a stiff resistance against the British in the summer of 1943.

See A. Holm, *Catania Antica* (trans. G Libertini) (Catania, 1925); F. de Roberto, *Catania* (Bergamo, Arti Grafiche, 1907).



[1]This is the form vouched for by the inscriptions.

CATANZARO, a town and episcopal see of Calabria, Italy, capital of the province of Catanzaro, 1,125 ft. above sea-level. Pop. (1936) 27,907 (town); 45,400 (commune). The station for the town (Catanzaro Sala) is on a branch connecting the two main lines along the east and west coasts of Calabria, 6 mi. N. by W. of Catanzaro Marina on the east coast, and 20 mi. E. of S. Eufemia Biforcazione, on the west coast line. The town enjoys a comparatively cool climate in summer, and commands fine views. Numerous wealthy families reside here. The town was bombed by the Allies in World War II.

CATAPHYLL, a botanical term denoting any rudimentary scalelike leaf which precedes the foliage leaves, as a bud scale, etc.

CATAPULT, a generic name for warlike engines of the crossbow type used by the ancients (Lat. *catapulta*, Gr. *καταπέλτης*). (*See* ENGINES OF WAR.) They are usually classed as (*a*) catapults and (*b*) ballistae (*λιθοβόλοι*). The former were smaller and were used with arrows for what is now called direct fire (*i.e.*, at low angles of elevation); the latter were large siege engines discharging heavy bolts or stones at a high angle of elevation, like the modern howitzer.

The essential parts of the catapult (see illustration) were the frame, the propelling gear, the trough (corresponding to the modern barrel) and the pedestal. The frame consisted of two horizontal beams forming top and bottom sills, and four strong upright bars mortised into them. The three open spaces or compartments resembling narrow windows, between these four uprights, carried the propelling and laying gear. The propelling gear occupied the two outer "windows." In each a thick skein of cord or sinews was fastened to the top and bottom sills and tightly twisted. The stiff wooden arms were inserted in the two skeins, and a specially strong bowstring joined the tips of these arms. In the middle compartment was the hinged fore-end of the trough, which was at right angles to the frame and at the back of it. The trough could be laid for elevation by a movable prop, the upper end of which was hinged to the trough, while the lower ran up and down a sort of trail fastened to the pedestal. The whole equipment was laid for "line" by turning the frame, and with it the trough, prop and trail by a pivot in the head of the pedestal. Sliding up and down in the trough was a block, fitted with a trigger mechanism, through which passed the middle of the bowstring. The pedestal was a strong and solid upright resting upon, and strutted to, a framework on the ground; its upper end, as mentioned above, took the pivot of the frame and the head of the trail.

CATAPULT USED IN ANCIENT SIEGE WARFARE
This engine, capable of discharging a 26 in. arrow weighing ½ lb., had an effective range of 400 yards

On coming into action the machine was laid for direction and elevation. The block and with it the bowstring was next forced back against the resistance of the twisted skeins to the rear end of the trough, this being effected by a windlass attachment. The trigger being then pressed or struck with a hammer, the bowstring was released from the block, the stiff arms were violently brought back to the frame by the untwisting of the skeins, and the arrow was propelled through the centre "window" with great velocity. A small machine of the type described weighed about 85 lb., and sent a "three-span" (26in.) arrow weighing ½ lb. at an effective man-killing velocity somewhat over 400yds.

The ballista was considerably larger and more expensive than this. In Scipio's siege train, at the attack of New Carthage (Livy xxvi. 47, 5), the number of the ballistae was only one-sixth that of the catapults. In the ballista the rear end of the trough (which projected in front of the frame) always rested upon the ground, or rather was fixed to the framework of the pedestal—which was a heavy trestle construction—and the trough was thus restricted to the angle of elevation, giving the maximum range (45°). Even so, the range was not appreciably greater than that of a catapult, and in the case of the largest ballistae (90-pounder) it was much less. These enormous engines, which, once in position, could not be laid on any fresh target, were used for propelling beams and stones rather than for shooting arrows, that is, more for the destruction of material than for man-killing effect. The skeins that supplied the motive force of all these engines were made of the sinews of animals, twisted raw hide, horsehair rope, and, in at least one celebrated case, of women's hair. In 146 B.C., the authorities of Carthage, having surrendered their engines to the Romans in the vain hope of staying their advance, new ones were hurriedly constructed, and the women and virgins of the city cut off their hair to supply the needed skeins.

The modern implement known as a "catapult" is formed by a forked stick, to the forks of which are attached the ends of a piece of elastic. To the middle of this elastic a pocket is fitted to contain a bullet or small stone. In use the forked stick is held in the left hand and the pocket drawn back with the right. Aim is taken and, the pocket being released, the missile flies through the fork of the stick. Though classed as a toy, this weapon can do considerable execution among birds, etc., when skilfully used. The name of "catapult" has also been given to a bowling machine which is used for cricket practice.

CATARACT, a waterfall (Gr. καταρράκτης, a floodgate, or waterfall, something which rushes down). The earliest use in English is of a floodgate or portcullis, and this survives in the name of a disease of the eye (*see* EYE, DISEASES OF; OPHTHALMOLOGY). The term is also used of a device to regulate the strokes in certain types of steam-engine.

CATARGIU (or CATARGI), **LASCAR** (1823–1899), Rumanian statesman, belonged to an ancient Walachian family, one of whose members had been banished in the 17th century by Prince Matthew Bassaraba and had settled in Moldavia. Under Prince Gregory Ghica (1849–56) Catargiu rose to be prefect of police at Jassy. In 1857 he became a member of the *Divan ad hoc* of Moldavia, a commission elected in accordance with the treaty of Paris (1856) to vote on the proposed union of Moldavia and Walachia. His strongly conservative views, especially on agrarian reform, induced the Conservatives to support him as a candidate for the throne in 1859. During the reign of Prince Cuza (1859–66) Catargiu was one of the Opposition leaders. On the accession of Prince Charles in May 1866 Lascar Catargiu became president of the council (prime minister); but finding himself unable to co-operate with his Liberal colleagues, I. C. Bratianu and C. A. Rosetti, he resigned in July. After eight more ministerial changes, culminating in the anti-dynastic agitation of 1870–71, Catargiu formed, for the first time in Rumanian history, a stable Conservative cabinet, which lasted until 1876. Impeachment of himself and his cabinet was threatened, but the proposal was withdrawn in 1878, and he remained in opposition until 1889, when he formed a short-lived cabinet, taking the portfolio of the Interior. In the Florescu ministry of March 1891 he occupied the same position, and in Dec. he again became president of the council, retaining office until 1895. He died at Bucharest on April 11, 1899.

CATARRH, a term chiefly signifying mild inflammation of the mucous membrance of the respiratory passages, in popular language a "cold." It is the result of infection by a micro-organism, especially *M. catarrhalis,* which may occasionally be a causative factor. Its pathogenic significance is slight.

The term catarrh is used in a wider sense to describe a similar pathological condition of any mucous surface in the body; *e.g.,* gastric catarrh, intestinal catarrh, etc. (*See* also ALIMENTARY SYSTEM, DISEASES OF THE; RESPIRATORY SYSTEM, DISEASES OF.)

CATARRHINE MONKEY, the term used (in contradistinction to Platyrrhine, *q.v.*) to describe those apes which have the nostrils approximated; the aperture pointing downward; and the intervening septum narrow. These are the distinguishing features of all the old world primates. (*See* PRIMATES.)

CATASTROPHE, in ancient Greek drama the change in the plot which leads up to the conclusion (Gr. καταστρέφειν, to overturn). Hence any sudden change, particularly of a disastrous nature, and, in earlier geological theories, a great convulsion of the earth's surface.

CATAWBA, the principal tribe of the eastern division of the Siouan stock of American Indians. The name is probably derived from the Choctaw *katápa,* meaning "divided" or "separated."

Formerly the dominant people of South Carolina, the Catawba also had divisions extending into North Carolina. In the 17th century the population was about 5,000, but by 1780 it had declined to about 500. By the beginning of the 20th century there were only about 60 members of the tribe.

The Catawba, who were at war with the Iroquois for a long time, furnished a valuable contingent to the South Carolina troops during the American Revolution. They retreated to Virginia upon the advance of British troops in 1870, but they later returned and occupied small towns on the Catawba river. They afterward leased their land and about 1841 sold all of it except one square mile to the state. At that time a number of them went to the territory of the Cherokee in western North Carolina, but they did not remain long with their former enemies and soon returned to South Carolina. A vocabulary of about 300 words, collected by Oscar M. Lieber, the geologist, in 1856, was published in *Collections of the South Carolina Historical Society,* vol. ii (1858).

See F. W. Hodge (ed.), *Handbook of the American Indians* (1912).

CATAWBA, an amber coloured, richly flavoured wine made from the light-red grape of the same name. The grape is a variety of the *Vitis labrusca,* a North American and Asiatic species, and takes its name from the Catawba river in North and South Carolina. In 1807 the grape was grown in Washington, D.C., but it was not until about 1823 that the name Catawba was given to it. It spread rapidly in New York, Ohio and Ontario and was extensively grown in the Finger lake section of New York. The vine is extremely prolific, the fruit being large and very sweet. The grapes are readily preserved, and their great use is partly accounted for by that fact. The wine is largely used as a base for champagne.

CATBALOGAN, a municipality (with administrative centre and 16 *barrios* or districts) and capital of the province and island of Samar, Philippine Islands. Pop. (1948) 26,839. It lies midway between the ports of Manila and Zamboanga and is a port of call for coastwise and other craft. Abacá (Manila hemp) is produced in the country tributary to the town and there are manufactures of woven fibres and mats which are also made from *tiking* (sedge). Most of these are exported. The fisheries are important. The vernacular is Samarino, a dialect of Bisayan. Of those inhabitants 6 to 19 inclusive, 21.6% attended school in 1939, and of those ten years old and over 37% were literate.

CATBIRD (*Dumetella carolinensis*), a North American bird of the thrasher family Mimidae, about 9 in. long, a summer visitor from the Gulf of Mexico, north to New Brunswick and Hudson Bay. Its plumage is slate-gray, with a black cap and tail and chestnut under tail coverts. It is noted for its beautiful song, with much of the charm of its close relative, the mocking-bird. The name expresses the mewing protest of the bird when angry. The catbird winters in the southern states, in Cuba and from Mexico to Panama. It is resident in Bermuda. In Australia, a name given to any one of several bowerbirds (*q.v.*), especially to *Ailuroedus crassirostris,* which builds no bower. The name comes from a catlike mewing.

CATBOAT, a small sailing-boat of the pleasure variety, having the mast stepped forward and carrying a single fore-and-aft mainsail set on a boom and gaff, known as a *cat rig.* They are also known as Una boats, and frequently carry a centre-board (*q.v.*).

CATCH, a form of concerted vocal music virtually indistinguishable from the round, save for the fact that it is always

humorous in character. The catch had its greatest vogue in earlier centuries, when also the words to which it was sung were too often more jocose than refined. Particulars of various collections available occupy a column of small print in Grove. Of the innumerable catch and glee clubs which existed in England in former days one, known simply as the Catch Club, founded as long ago as 1761, still exists. (*See* also under CANON; CONTRAPUNTAL FORMS; GLEE; RONDEL.)

CATCH-CROPS are rapidly growing crops that occupy the soil for short periods of time to absorb or "catch" nitrates that might otherwise be carried away in drainage waters. They are usually grown between the times of two principal crops or between the rows of another crop. Rye, oats and vetch are frequently used, but other crops and plants, including weeds, may serve as well. When the immature plants are plowed under, the nitrogen absorbed is returned to the soil where it can again be used to nourish other plants. Many gardeners and farmers have found that they can improve their production efficiency by giving attention to the use of catch-crops in their cropping systems.

In practice, however, the term catch-crops is often used with other meanings. Some regard them as quickly maturing crops grown between two principal crops for the purpose of keeping the land completely utilized. Defined in this way, catch-crops may occupy idle land for longer periods of time and include more species of plants than under the more restricted definition given above. The crops serving as catch-crops will be useful, not only for conserving nitrates, but also for soil protection, soil enrichment and as additional sources of feed for livestock.

Special crops planted between two principal crops for the purpose of protecting the soil against water and wind erosion are frequently called cover-crops. They may also function as catch-crops and as sources of organic matter for soil enrichment.

Crops planted between two principal crops, chiefly for the purpose of soil enrichment, are more accurately described as green manure crops. Legumes, because of their ability to obtain nitrogen from the atmosphere, are used more frequently for this purpose than non-legume crops. In the North American corn-belt, for instance, biennial sweet clover, a deep rooted legume, is widely used as a green manure crop. It is seeded in early spring in either fall- or spring-seeded grains and plowed under the following spring for corn. If conditions are favourable, as much as 100 lb. or more of atmospheric nitrogen and several tons of organic matter rich in nutrient minerals may be added to an acre of land. In addition to these benefits, the sweet clover or other green manure crops may also serve as catch and cover crops.

In view of the overlapping functions of catch, cover and green manure crops, it is difficult to use these classifications accurately. Some call all special crops planted between two principal crops catch-crops, while others use the designations that best express the major purposes for which the crops are grown. (F. C. BR.)

CATCHMENT AREAS. The term "catchment area" is used to describe the collecting area from which water would flow to a stream or river, the boundary of the area being determined by the ridge separating water flowing in opposite directions. The amount of water collected within the catchment area would depend on the extent of that area, the amount of rain which has fallen on the surface, and the proportion of that rainfall which has been lost by evaporation or absorption. The term "run-off" has been adopted to describe that portion of the rainfall which ultimately finds its way to the stream, and the ratio between the rainfall and the "run-off" varies widely, according to the climatic conditions. In England and Scotland the average annual rainfall varies from a little over 20 in. to 175 in., and the annual loss by evaporation from a land surface varies from about 10 to 18 in., being less in the north, increasing towards the south.

Evaporation.—The loss by evaporation depends on the hours of sunshine, the temperature, and the humidity of the atmosphere, and varies greatly during the different periods of the year as might naturally be expected. The following average figures for the period 1883–1900 illustrate the effect of these various factors on the proportion of the rainfall which flowed over Teddington weir from the Thames catchment area above that point.

	Average hours of sunshine.	Average temperature.	Average humidity.	Proportion of rainfall flowing over Teddington weir.
		Degrees.	Degrees.	Per cent.
Jan.–March .	57·5	39·6	84·5	60·9
April–June .	163·2	53	74·3	30
July–Sept. .	159·8	60·2	75·7	12
Oct.–Dec. .	46·1	41	86·5	28

The total annual loss by evaporation in Britain is less in regions of high rainfall than in areas of low rainfall, and the seasonal loss varies in a similar manner. The influence of climatic conditions on the evaporation is so marked, that in tropical countries the proportion of the rain which flows off the ground is small.

It has been held that forests tend to increase the discharge of a river by reducing evaporation, but such evidence as has been obtainable fails to support this view. Shade cast by the trees would reduce evaporation, but rain which would otherwise flow from the ground, is absorbed by the trees. Although forests have but little effect on the annual loss by evaporation, their presence has an influence in delaying the flow of water from the hillsides, and when a catchment area has been cleared of timber, floods tend to become more intense.

Evaporation from a water surface is greater than from a land surface, especially in tropical countries, and is a matter of importance when lakes occupy a considerable proportion of the catchment area.

Absorption.—The amount of rain falling on the surface which percolates downwards depends on the porosity of the surface soil and the nature of the underlying rock, whether impermeable, porous, or fissured.

When the surface is impermeable, there would be no loss by percolation.

When the surface is permeable but is underlain by impermeable rock, water percolates downwards till that rock is reached and then travels underground in the direction of the steepest inclination of the rock surface, which is generally towards the stream, water lost by percolation reappearing as springs. Such percolation has little influence on the annual run-off, but may have a marked effect on its variations throughout the year. Thick beds of permeable material, such as sand or gravel, absorb large volumes of water, acting as natural storage reservoirs. During periods of abundant rainfall the beds would become saturated, and during periods of dry weather water so absorbed would be gradually discharged, thus maintaining a considerable flow in the stream.

This point is of great importance when it is desired to utilize the water of a stream without constructing a storage reservoir to balance its fluctuations, as the quantity of water which could be taken during certain periods would be limited to the dry weather flow.

When the surface is permeable and is underlain with permeable or fissured rock, such as chalk, the entire rainfall on the catchment area might percolate downwards, reappearing in the form of springs issuing either within or without the limits of the catchment area.

In the former case there would be no surface flow above the point where the springs break out, and in the latter, the whole catchment area would be void of streams. (W. J. E. B.)

CATECHISM, a compendium of instruction (particularly of religious instruction) arranged in the form of questions and answers. The custom of catechizing was followed in the schools of Judaism and in the Early Church, where it helped to preserve the Gospel narrative. (*See* CATECHUMEN.)

The catechism as we know it is intended primarily for children and uneducated persons. Its aim is to instruct, and it differs from a creed or confession in not being in the first instance an act of worship or a public profession of belief. The first regular catechisms seem to have grown out of the usual oral teaching of catechumens, and to have been compiled in the 8th and 9th cen-

turies. They continued on through the Middle Ages to the 16th century. The original of all modern catechisms, because of its question and answer form, is the *Disputatio Puerorum Per Interrogationes Et Responsiones* (*Patr. Lat.*, CI, 1097–1144), of the 9th century. In the 12th century the *Elucidarium* of Honorius of Autun (*Patr. Lat.*, CLXXII, 1110–1176) and the *De Quinque Septenariis* of Hugh of St. Victor (*Patr. Lat.*, CLXXV, 405–414) were well known and had much influence on subsequent catechisms. Jean Gerson (1363–1429), chancellor of the University of Paris, took great interest in catechizing, taught children both at Paris and Lyons, and wrote among other catechetical works his *ABC des simples gens*. The first catechism printed in Germany was the *Christenspiegel* of Coelde, which first appeared in 1470, proved very popular and was in its 5th edition by 1514. But though catechisms had already been in use, the 16th century saw a tremendous increase in their number and importance, as ever-increasing facilities for printing were available and the age of the Reformation began. Both the new Protestant Churches and the Catholic Church strove zealously to instruct their members and to win new adherents.

In 1520 Luther had brought out a primer of religion dealing briefly with the Decalogue, the Creed and the Lord's Prayer; and other leaders had done something of the same kind. In 1529 all these efforts were superseded by Luther's Smaller Catechism meant for the people themselves and especially for children, and by his Larger Catechism intended for clergy and schoolmasters. These works did much to mould the character of the German people and powerfully influenced other compilations.

In 1537 John Calvin at Geneva published his catechism for children. It was called *Instruction and Confession of Faith for the use of the Church of Geneva* and explained the Decalogue, the Apostles' Creed, the Lord's Prayer and the Sacraments. It was the work of a man who knew little of the child mind, and, though it served as an admirable and transparent epitome of his famous *Institutes*, it was too long and too minute for the instruction of children. Calvin came to see this, and in 1542 drafted a new one which was much more suitable for teaching purposes. This was used in Geneva and in Scotland. The Reformed churches of the Palatinate, on the other hand, used the Heidelberg Catechism (1562–63), mainly the work of two of Calvin's disciples, Kaspar Olevianus and Zacharias Ursinus. This work is perhaps the most widely accepted symbol of the Calvinistic faith, and is noteworthy for its emphasis on the less controversial aspects of the Genevan theology. As revised by the synod of Dort in 1619, it became the standard of most of the Reformed churches of central Europe, and in time of the Dutch and German Reformed Churches of America.

Since 1648 the standard Presbyterian catechisms have been those compiled by the Westminster assembly, presented to parliament in 1647, and then authorized by the General Assembly of the Church of Scotland (July 1648) and by the Scottish parliament (Jan. 1649). The Larger Catechism is "for such as have made some proficiency in the knowledge of the Christian religion," but is too detailed and minute for memorizing, and has never received anything like the reception accorded to the Shorter Catechism, which is "for such as are of weaker capacity." The work was done by a committee presided over first by Herbert Palmer, master of Queens', Cambridge, and then by Anthony Tuckney, master of Emmanuel. The Shorter Catechism, after a brief introduction on the end, rule and essence of religion, is divided into two parts: I. The doctrines we are to believe (1) concerning the nature of God, (2) concerning the decrees of God and their execution. II. The duties we are to perform (1) in regard to the moral law, (2) in regard to the gospel—(*a*) inward duties, *i.e.*, faith and repentance, (*b*) outward duties as to the Word, the sacraments and prayer. It has 107 questions and answers, while that of the Anglican Church has but 24, grouping as it does the ten commandments and also the petitions of the Lord's Prayer, instead of dealing with them singly.

Though the Catholic Church had long been using catechisms, they were multiplied with new emphasis as the Church swung into the Counter Reformation. The most famous was that of the Jesuit Peter Canisius, first published in 1555. It went through 400 editions within 150 years. Another catechism which had a large circulation and greatly influenced later works was that of Bellarmine (1597); in France those of Auger (1563) and Bossuet (1687) were outstanding. The *Catechism of the Council of Trent*, completed in 1566, was never intended as an ordinary catechism. It was written for and addressed to parish priests, to serve as model and guide in their instructions and sermons to the people. The Catholic Church, because its unity of doctrine is otherwise so safeguarded, has never adopted any one official catechism for all its members. Each bishop is free to adapt his method of instruction to local conditions. Many bishops themselves, however, have desired a universal catechism; at the Vatican council (1870) the project was seriously discussed, with Bellarmine's catechism proposed as model. In more recent times well known catechisms have been the *Baltimore Catechism* (1885) in the United States, the *Penny Catechism* in England, and that of Deharbe (1847) in Germany. In the present century, pedagogical-catechetical congresses and periodicals (e.g., *Journal of Religious Instruction*, Joseph F. Wagner, N.Y.) have stimulated new methods, which methods in turn have produced new catechisms and aids. The classic survey of this period is *Où En Est L'Enseignement Religieux?* (Louvain, 1937), which lists and appraises the books and methods of the different countries.

Peter Mogilas, in 1643, composed the *Orthodox Confession of the Catholic and Apostolic Eastern Church*. This counteraction to the activities of the Jesuits and the Reformed Church was standardized by the synod of Jerusalem in 1672. A smaller catechism was drawn up by order of Peter the Great in 1723. The catechisms of Levshin Platon (1762) and V. D. Philaret (1839), each in his day metropolitan of Moscow, are bulky compilations which cannot be memorized, though there is a short introductory catechism, prefaced to Philaret's volume (Eng. trans. in Blackmore's *Doctrine of the Russian Church, 1845*).

The catechism of the Church of England is included in the Book of Common Prayer. It has two parts: (i) the baptismal covenant, the Creed, the Decalogue and the Lord's Prayer drawn up probably by Cranmer and Ridley in the time of Edward VI, and variously modified between then (1549) and 1661; (ii) the meaning of the two sacraments, written on the suggestion of James I at the Hampton Court conference in 1604 by John Overall, then dean of St. Paul's. This supplement to what had become known as the Shorter Catechism established its use as against the longer one, *King Edward VIth's Catechisme* which had been drawn up in 1553 by John Ponet, bishop of Winchester, and enlarged in 1570 by Alexander Nowell, Overall's predecessor as dean of St. Paul's. By the rubric of the Prayer Book and by the 59th canon of 1603, the clergy are enjoined to teach the catechism in church on Sundays and holidays after the second lesson at Evening Prayer. This custom, long fallen into disuse, has largely been revived during recent years, the children going to church for a special afternoon service of which catechizing is the chief feature. Compared with the thoroughness of most other catechisms this one seems scanty, but it has a better chance of being memorized, and its very simplicity has given it a firm hold on the inner life and conscience of devout members of the Anglican communion throughout the world.

Almost every Christian denomination has its catechism or catechisms. Besides those already enumerated there are two interesting joint productions. In 1898 the National Council of the Evangelical Free Churches in England and Wales published an *Evangelical Free Church Catechism*, representing directly or indirectly the beliefs of 60 or 70 millions of avowed Christians in all parts of the world, a striking example of inter-denominational unity. *The School Catechism* was issued in 1907 by a conference of members of the Reformed churches in Scotland, which met on the invitation of the Church of Scotland. In its compilation representatives of the Episcopal Church in Scotland co-operated, and the book, though "not designed to supersede the distinctive catechisms officially recognized by the several churches for the instruction of their own children," certainly "commends itself as

suitable for use in schools where children of various churches are taught together."

During the 19th century in the United States the Sunday school was recognized by various Protestant denominations as the primary instrument for religious instruction. By the middle of the century the Bible was regarded as primary curriculum material, the catechism secondary, though still important.

See the *Encyclopaedia of Religion and Ethics, s.v.* (A. J. G.; X.)

CATECHU or CUTCH, an extract obtained from several plants (the derivation is from the Malay *Kachu*), its chief sources being the wood of two species of acacia (*A. catechu* and *A. suma*), both natives of India. This extract is known as black catechu. A similar extract, known in pharmacy as pale catechu (*Catechu pallidum*), and in general commerce as gambir, or *terra japonica*, is produced from the leaves of *Uncaria gambir* and *U. acida*, cinchonaceous plants growing in the East Indian archipelago. A third product to which the name catechu is also applied is obtained from the fruits of the areca or betel palm, *Areca catechu*. Ordinary black catechu is usually imported in three different forms. The first and best quality, known as Pegu catechu, is obtained in blocks externally covered with large leaves; the second and less pure variety is in masses, which have been moulded in sand; and the third consists of large cubes packed in coarse bags. The wood of the two species of *Acacia* yielding catechu is taken for the manufacture when the trees have attained a diameter of about one foot. The bark is stripped off and used for tanning and the trunk is split up into small fragments which are covered with water and boiled. When the extract has become sufficiently thick it is cast into the forms in which the catechu is found in commerce.

Catechu so prepared is a dark brown or, in mass, almost black substance, brittle, and having generally a shining lustre. It is astringent, with a sweetish taste. In cold water it disintegrates, and in boiling water, alcohol, acetic acid and strong caustic alkali it is completely dissolved. Chemically it consists of a mixture of a peculiar variety of tannin termed catechutannic acid with catechin or catechuic acid, and a brown substance due to the alteration of both these principles. Catechutannic acid is an amorphous body soluble in cold water, while catechin occurs in minute, white, silky, needle-shaped crystals which do not dissolve in cold water. A minute proportion of quercetin, a principle yielded by quercitron bark, has been obtained from catechu.

Gambir.—Gambir, which is similar in chemical composition to ordinary catechu, occurs in commerce in the form of cubes of about an inch in size with a pale brown or yellow colour and an even earthy fracture. For the preparation of this extract the plants above mentioned are stripped of their leaves and young twigs and these are boiled down in shallow pans. The juice is strained off, evaporated, and when sufficiently concentrated is cast into shallow boxes, where, as it hardens and dries, it is cut into small cubes. Gambir and catechu are extensively employed in dyeing and tanning. For dyeing they have been in use in India from the most remote period, but it was only during the 19th century that they were placed on the list of European dyeing substances. Catechu is fixed by oxidation of the colouring principle, catechin, on the cloth after dyeing or printing; and treated thus it yields a variety of durable tints of drabs, browns and olives with different mordants (*see* DYEING). The principal consumption of catechu occurs in the preparation of fibrous substances exposed to water, such as fishing lines and nets, and for colouring stout canvas used for covering boxes and portmanteaus under the name of tanned canvas. Gambir is used medicinally as an astringent, especially in the treatment of diarrhoea. It is no longer included in the United States *Pharmacopoeia*. In Great Britain, pale catechu is the official term.

CATECHUMEN, a technical term applied to a person receiving instruction in the Christian religion with a view to baptism (Gr. *κατηχούμενος*, one receiving instruction, from *τηχεῖν*, to teach orally). The catechumenate grew naturally out of Judaism, which as a missionary religion had to instruct recruits. These were admitted by circumcision and baptism, women by baptism only. Second-century practice in Palestine is described in *Yebamot* 47 a.b., "They acquaint him with some of the lighter and some of the weightier commandments. . . . As they show him the penalty of breaking commandments, so they show him the reward of keeping them. . . . If he accepts, they circumcise him forthwith . . . when he is healed they at once baptize him." The ordeal was clearly much lighter for women. For this and other reasons there was a considerable body of potential proselytes on for fringe of Judaism. They were known as "God-fearers"; if they shrank from circumcision themselves, they generally had the rite performed on their sons (G. F. Moore, *Judaism*, i, 323 ff.).

The Apostles are said to have instructed converts after baptism (Acts ii, 41–42); the earliest teaching was presumably an explanation of the Messianic prophecies in the Old Testament. On the gentile mission Paul's strongest appeal was made to the "God-fearers," who had been already won for monotheism and Jewish standards of morality, and for whom circumcision was no longer necessary. The word *κατηχεῖν* applied to Christian instruction, presumably both before and after baptism, occurs in the New Testament in Luke i, 4 (of Theophilus), Acts xviii, 25 (of Apollos—the exact meaning is disputed; *see* APOLLOS) and Gal. vi, 6 ("let him that is *taught* communicate with him that *teacheth* in all good things"). As the gentile element in the church preponderated, instruction became more definite. It was probably undertaken by the "teachers" (1 Cor. xii, 28). *The Teaching of the Twelve Apostles*, i–vi, is a manual of ethical teaching. The *Shepherd* of Hermas was widely used (Eus. *H. E.* III, iii, 6). Justin Martyr (*Apol.* i, 61) says converts are taught to pray for forgiveness before baptism.

In the 4th century, with the rise of heresy, detailed doctrinal teaching was given. Of those treatises which have survived, the most important are Cyril of Jerusalem's *Catechetical Lectures*, Gregory of Nyssa's *Catechetical Oration*, and Augustine's *De Rudibus Catechizandis*. By this time the postponement of baptism had become general; thus Constantine was not baptized till he was at the point of death. Accordingly a large proportion of Christians belonged to the catechumenate. Most of them were merely "adherents" of the church; others were under definite instruction for baptism. The preparation, preceded probably by a period of probation, generally coincided with the 40 days of Lent, the baptism taking place on Easter eve. The preparation consisted of (1) instruction in what must be renounced, (2) instruction in the faith, (3) exorcisms of evil spirits (*see* BAPTISM). All catechumens attended the first part of the Eucharistic service, known in the west as *Missa Catechumenorum*, after which they were "dismissed." As infant baptism became general, the catechumenate decayed. The baptismal rites now used are clearly adaptations of rites intended for the reception of adult catechumens. In the mission field the catechumenate has been revived and primitive conditions are repeated. Thus a polygamist will often be a lifelong "adherent" debarred from baptism by marriage difficulties of his own making. (W. K. L. C.)

CATEGORICAL, in common usage, means "unconditional" or "direct and explicit in statement"; also, "pertaining to a category."

1. *In Traditional Logic.*—The word is derived, as Petrus Hispanus tells us (in *Summulae Logicales, c.* 1245), from the Aristotelian *κατηγορούμενον* ("predicate") and thus means "predicative." (*See* LOGIC for an account of the traditional categorical propositions and categorical syllogism.)

2. *In Mathematics.*—A set of postulates is said to be categorical if every two models of the postulates are isomorphic. For example, in the case of Peano's postulates for arithmetic (*see* POSTULATE), a model is a system of meanings for the three primitive terms, "0", "number," "successor," which renders all the postulates true. That the postulates are categorical means that any two such models are isomorphic. *I.e.*, given two models, it is always possible to find a correspondence between the numbers of one model and the numbers of the other model, such that every number of either one of the models corresponds to a unique number in the other model, such that the 0 of one model corresponds to the 0 of the other model, and such that, if the numbers x, y of one model correspond to the numbers x', y' of the other model respectively, then y' is the successor of x' in the second model if and only if y is the successor of x in the first model. A categorical set of postulates thus determines uniquely the mathematical structure of a model, and in this sense no additional postulates are required (as distinguished from possible additional logical axioms [*see* AXIOM]). (A0. C.)

3. *In Ethics.*—Kant introduced the term "categorical imperative" for a moral law that is unconditional or absolute, or whose validity or claim does not depend on any ulterior motive or end. According to Kant there is only one such categorical

imperative, which he formulates variously. One formula is: "Act only on such a maxim as you can will that it should become a universal law." This is purely formal, and expresses the condition of the rationality of conduct, rather than the condition of its morality. Another formula given by Kant is: "So act as to treat humanity, whether in your own person or in another, always as an end, and never as only a means." (*See* KANT, IMMANUEL and ETHICS, HISTORY OF.)

CATEGORICAL IMPERATIVE: *see* CATEGORICAL.

CATEGORY. The word "category" has come in unphilosophical contexts to mean much the same as "class," "type" or "kind." Recruits to the armed forces may be put into different categories, according to their physical qualities or according to their technical qualifications.

Originally the word belonged to Greek legal parlance, in which it meant "that of which a person is accused." Aristotle borrowed it for the special purposes of logical theory. In his use the Greek verb from which "category" derives meant "to predicate something of something"; *e.g.*, to assert of Socrates that he is a man, or is mortal, or is married to Xanthippe. Concentrating his attention upon simple assertions of the pattern "Socrates is such and such," Artistotle noticed that there are many important differences between the sorts of predicates that can be asserted of Socrates. To assert that Socrates is a man is to give a piece of information about Socrates of a radically different kind from that given by the assertion that Socrates is pale or that Socrates is older than Alcibiades. The first assertion tells us what Socrates is; the second tells us only what, at a particular moment, he is like in a particular respect; the third tells us only the result of a particular comparison between Socrates and Alcibiades. To put this point in another way, predicates like ". . . is a man" yield answers to the question "What is Socrates?"; predicates like ". . . is pale" yield answers to the question "What-like (*qualis*) is Socrates?"; predicates like ". . . in the market place" yield answers to the question "Where is Socrates?"; and so on. No answer to the question "Where is Socrates?" or "How big is Socrates?" is any answer to the question "What is Socrates?"; and no answer to the question "What is Socrates?" is any answer to the question "Where is Socrates?" or "What is Socrates now doing?" Predicates belong to different kinds or types; they yield answers to different questions.

Aristotle came to use the Greek word from which our noun "category" derives to signify not just predicate, but predicate *type*. "Man" and "monkey" are different predicates, but they are predicates of the same type or category. "Socrates is a man" is one answer, "Socrates is a monkey" is another, though false, answer to the question "What is Socrates?" Aristotle listed sometimes ten, sometimes fewer categories or predicate types and coined technical titles for them, some of which came direct from common Greek interrogative words like our "What?" and "How big?" The later latinization of Aristotelian logic originated our category titles like "quality," "quantity," "relation," "substance," "state" (or "condition") and others.

This distinction between kinds of predicate was required by Aristotle in order to resolve a number of logical paradoxes. For example, Socrates could, in the course of a short time, cease to be taller and come to be shorter than Alcibiades; so he is not at the later date what he was at the earlier date. Yet he does not cease to be a human being. How can he not be what he used to be (namely taller than Alcibiades) and still be what he used to be (namely a human being)? The answer is that a change of relation is not a change of sort. Similarly, Socrates who was pale yesterday may be flushed today, without his ceasing to be what he was yesterday, namely older than Alcibiades. A change of (colour) quality (of face) is not a change of (temporal) relation (between dates of birth). Aristotle also noticed the important point that the same word may be employed sometimes in one category and sometimes in another. We may describe a person, a regimen and a place as healthy, yet a place or a course of exercise cannot be well or unwell. To call a place or a regimen "healthy" is to say that it makes or causes people to be in good health. "Healthy" can mean "health-causing," or it can mean "health-enjoying," and the things that can be asserted or denied to be health-causing will or may be entirely different from the things, namely human beings and other living organisms, which can be asserted or denied to be in good health. A few words are category-pervasive. The notions of *being*, *one* and *good* appear, in different modifications, in every category. Such terms came later to be called "transcendentals."

Aristotle himself showed no particular veneration for his lists of sometimes ten, sometimes fewer predicate types. He did not attempt to prove that his lists were exhaustive or that they did not contain some redundancies. Piety induced some of his followers to assume that all conceivable predicates must be lodged in one or other of Aristotle's ten niches; considerations of economy have induced other thinkers to compress the list of irreducible predicate types to two or three. The categories of quality and relation have been held to exhaust the radical predicate types. More harm than good has been done by such economies.

There is however one traditional amplification of Aristotle's basic scheme which, whether or not it was intended by Aristotle himself, has proved important in philosophy and logical theory. The subject term of a proposition of the pattern "Socrates is a man" or "Socrates is elderly" cannot be classified with any of the possible predicates in such propositions. The name of a particular person or thing or event is not the name of a sort or a quality or a relation or a magnitude, etc. Socrates is of a sort, for he is a man; he has qualities, for he is white and wise; he is in relations, for he is married to Xanthippe; and so on. But he is not himself a sort, a quality, a relation or a magnitude, etc. The word "Socrates" could not yield the answer to any question of the form "Of what sort is this?", "Where is it?", "How big is it?" Instead, it has been held that a word like "Socrates" stands for a particular "substance," and "substance" has consequently been used as the title of a type of term which is not a predicate term, but a subject term. Various things can be asserted and denied of Socrates, but "Socrates" cannot be predicated, truly or falsely, of anything. It is not a possible predicate word. The idea that there may be various types of subject terms, as there are various types of predicates, has not been systematically developed—partly because the whole program of breaking all propositions alike down into subjects and predicates has come under effective criticism.

Kant converted the word "category" to a special use of his own, though he clearly believed that his scheme of ideas was closer to Aristotle's than it actually is. Kant was not interested in the different types of predicates predicable of a particular subject or substance, like Socrates. He was interested in the different types of judgment or proposition. In the three propositions "Socrates is mortal," "all men are mortal" and "some men are mortal," the predicates are not merely of the same type. They are the same predicate. But the three propositions differ from one another in another respect, that of what is sometimes called "logical form," in that the first is singular, being about one designated individual, the second is universal, being about every member of the class of men, while the third is particular, in being about some (at least one) undesignated members of the class of men. Socrates might be mortal without all men being mortal; Socrates could not be mortal without at least one member of the class of men being mortal, given that Socrates is a man. But some men might be mortal without Socrates being mortal; and we might know that all men are mortal without knowing that Socrates is mortal; since we might not know that Socrates was a man or even that there was anyone called "Socrates."

These differences of logical form are bound up with the implicational differences between the forces of "all . . . ," "some . . ." and "this . . ." (or "he" or "Socrates"). Other such differences are those hinging on the presence or absence of "not" (or some equivalent), the presence or absence of "if" or "or" (or their equivalents) and the presence or absence of "must" or "may" (or their equivalents). So, while Aristotle's list of categories derived from the study of the different types of predicates in simple, singular, affirmative propositions, Kant's doctrine starts from the consideration of the logically cardinal differences between simple and compound propositions, between affirmative and negative propositions, between universal, particular and singular propositions and between assertoric, apodictic and problematic propositions. Kant

was not interested in the differences that had interested Aristotle.

For Aristotle, the notions of quality and quantity (or magnitude) were the types of such predicates as "white" or "sweet" and "six feet tall" or "three hundredweight" respectively. For Kant, differences of "quality" are, in the first instance, the differences between affirmative and negative propositions, and differences of "quantity" are the differences between universal, particular and singular propositions. For Aristotle, "being taller than" signifies a different relation from "being older than." For Kant, "if a metal is heated, it expands" expresses a different relation from that expressed by "this metal is expanding" or that expressed by "either today is Monday or today is Tuesday."

Kant, then, borrowed and transformed the Aristotelian title of "category" and some of the Aristotelian subtitles, like "quality," "quantity" and "relation." But he employed them to mark not just the differences between the logical structures of propositions, but something closely co-ordinated with them. Scientific knowledge, the sort of knowledge to which Isaac Newton had contributed so much, is expressed in systems of propositions or judgments. So too are metaphysical speculations. Propositions of both sorts would have to be of some logical form or other, either negative or affirmative; either universal or particular or singular; either categorical or hypothetical or disjunctive; either assertoric, apodictic or problematic.

But the propositions expressing knowledge of things in space and time embody these logical forms only in a specially restricted way, namely so as to be applicable to what human minds can perceive. The purely logical structure of subject-predicate belongs to any simple, singular, assertoric, affirmative proposition; but for a proposition of this structure to express empirical knowledge, it must assert that a spatiotemporal thing has at a given time a certain quality or is for a certain time in a certain state. The subject-predicate structure has, so to speak, to be geared down to the domain of perceivable things and happenings. Similarly, a proposition of natural science may be of the logical structure "if X, then Y"; but it cannot be merely of this structure. For it to apply to the actual world, it must assert a dependence of one temporal state of affairs from another; *i.e.*, a causal connection between events. Kant's categories are the ways in which the propositional structures extracted in logical theory function as the controlling principles of natural knowledge. The world disclosed by a Galileo or a Newton is a world of substances existing in space and time, changing and interacting according to causal laws. The questions that we put to nature are not whether there are substances existing, changing and interacting, but what substances there are and in what ways they change and interact.

At least a part of Kant's purpose was to explain the insolubility of certain speculative or metaphysical problems by showing that the very posing of these problems presupposed that the categories of, say, substance and causality apply as well to what is not as to what is empirical or phenomenal. He claimed to have proved, on the contrary, that the field of application of these and the other categories was as wide and only as wide as the field of what we human beings do or might perceive. There are and must be answers to our causal questions about empirically ascertainable events; there can be no answers to parallel questions about supposed states of affairs transcending human experiment and observation. Since Kant, the term "category" has tended to disappear from the technical parlance of philosophers and logicians. It has, perhaps, been so heavily loaded with disparate Aristotelian and Kantian connotations that philosophers and logicians have tried to find more noncommittal titles for their basic distinctions. The word "type" and the phrase "logical type," introduced by Bertrand Russell, have tended to displace the word "category," though it must not be supposed that either Aristotle's "category" or Kant's "category" is equivalent to Russell's "logical type."

One point needs further discussion. If we ask what Aristotle thought that his category-titles were titles of, no certain or unambiguous answer can be given. They were indeed titles for types of predicate, or, more broadly, types of "terms" (predicates *or* subjects) of simple, singular propositions. But to say this leaves open the question whether by "predicates" or, more broadly, "terms" we are referring (1) to the grammatical elements into which certain sorts of sentences are analyzed or (2) to things or entities for which such grammatical elements stand. Was Aristotle intending to classify certain classes of parts of speech, or was he intending to classify real things? Was he contributing to a branch of philology, or to the higher reaches of general taxonomy? Neither answer would be satisfactory; nor can either answer be safely fathered on to Aristotle.

Distinctions more or less akin to those which Aristotle drew are nowadays apt to be described not indeed as grammatical but as "semantic" distinctions—distinctions, that is, between kinds or modes of significance. We can and for certain purposes we need to exhibit the general way or ways in which, for example, what is meant by "or" (or "*ou*" or "*oder*") differs from what is meant by "green" (or "*vert*" or "*grün*"). What is meant by the word "or" (or any equivalent expression) is clearly not a thing or a happening. So to specify its semantic function is not to put a thing or a happening into a species or a genus. On the other hand, to specify its semantic function is not just to say that "or" is an English conjunction, since what is being specified is not English as opposed to German or vice versa. On this view a category is a type of semantic function, neither a kind of linguistic expression nor yet a kind of thing or happening.

A child might be puzzled by the fact that while travellers can touch and photograph the North sea, travellers to the north pole can neither touch nor photograph it. It has to be explained to him not that the north pole differs from the North sea as an object, such as glass or air, differs from another object, such as wood or smoke, but rather that the expression "the north pole" and its equivalents do not have the same sort of meaning as the expression "the North sea" and its equivalents. "The North sea" is used to refer to a body of water in a certain place, whereas "the north pole" is used to refer to a certain place—*at* which there may indeed be now one ice hummock and now another. It is not itself an object. In short the expressions have different kinds of semantic function. Their meanings are of different logical types or of different categories. (G. R.)

CATENA, VINCENZO DI BIAGIO (*c.* 1480–1531), Venetian painter, formerly wrongly identified with Vincenzo dalle Destre of Treviso. In 1506 he and Giorgione were in partnership, as we learn from the inscription on the back of Giorgione's "Portrait of a Young Woman" in Vienna. He developed under the influence of Giovanni Bellini but there is no evidence that he ever worked in the Bellini studio. Characteristic early signed works are the "Virgin and Child with Saints and Donors" formerly in the Mond collection, the "Holy Family With a Saint" in Budapest, Hung., and the "Doge Leonardo Loredan Before the Virgin" in the Correr museum, Venice, It. The last two works are of about 1506, the time of Catena's documented association with Giorgione, and it is surprising to find that they are still entirely Bellinesque in character. A "Portrait of a Young Man" of this period is in the National gallery, London, Eng. The development of more advanced elements in his style may be traced in the "Virgin and Child with Saints and a Donor" at Liverpool, the "Holy Family with Saints and a Donor" in Berlin, Ger., and the "St. Jerome in His Study" (*c.* 1513) in London. The "Delivery of the Keys" in the Prado shows him under the influence of Palma Vecchio. A group of works showing Raphaelesque influence is often dated to his last years but may perhaps find better place in the period 1515–20. This influence first appears in the signed "Portrait of a Man" in Vienna and reaches its climax in the "Holy Family with St. Anne" at Dresden, Ger., which is based directly on a design from Raphael's studio. Giorgionesque and Titianesque influence flowers belatedly in the "Martyrdom of St. Christina" in the church of Sta. Maria Materdomini, Venice (1520). The successful fusion of the old and new in Venetian painting which this picture displays is Catena's particular achievement and characterizes the work of the last decade of his activity, culminating in the "Judith" of the Querini-Stampalia gallery, Venice, and the "Warrior Adoring the Infant Christ" in London. Characteristic late portraits are the "Giangiorgio Trissino" in the Louvre, Paris, "Venetian Senator" in New York city and the "Doge Andrea Gritti" (ascribed to Titian) in London.

CATENARY: *see* CURVES, SPECIAL.

CATERAN, the band of fighting men of a Highland clan (Gaelic *ceathairine*, a collective word meaning peasantry); hence the term is applied to the Highland, and later to any, marauders or cattle lifters.

CATERHAM AND WARLINGHAM, an urban district (with Whyteleafe, Woldingham and Chaldon) in the E. Surrey parliamentary division, England, 18 mi. S. of London. Pop. (1951) 31,293. Area 12.9 sq.mi. In the North Downs, Caterham has grown since the opening of the railway in 1856 (electrified 1928) into a residential town with engineering, perfumery and other light industries. The depot of the brigade of guards is in the district.

CATESBY, ROBERT (1573–1605), English conspirator, son of Sir William Catesby of Lapworth, Warwick, prominent recusant, was born in 1573, and entered Gloucester hall (now Worcester college), Oxford, in 1586. In 1596 he was one of those arrested on suspicion during an illness of Queen Elizabeth I. In 1601 he took part in the rebellion of Essex, was wounded in the fight and imprisoned, but finally pardoned on the payment of an

enormous fine. In 1602 he dispatched Thomas Winter and the Jesuit Tesimond *alias* Greenway to Spain to induce Philip III to organize an invasion of England, and in 1603, after James's accession, he was named as an accomplice in the "Bye plot." Exasperated by his personal misfortunes and by the repressive measures under which his co-religionists were suffering, he was now to be the chief instigator of the Gunpowder plot. The idea seems first to have entered his mind in May, 1603. About the middle of Jan. 1604 he imparted his scheme of blowing up the Parliament house to his cousin Thomas Winter, subsequently taking in Guy Fawkes and several other conspirators. But his determination not to allow warning to be given to the Roman Catholic peers was the actual cause of the failure of the plot. A fatal mistake had been made in imparting the secret to Francis Tresham, in order to secure his financial assistance; and there is little doubt that he was the author of the celebrated letter to his brother-in-law, Lord Monteagle, which betrayed the conspiracy to the government on Oct. 26. On receiving the news, Catesby exhibited extraordinary coolness; he refused to abandon the attempt, and his confidence was strengthened by Fawkes's report that nothing in the cellar had been touched or tampered with. After the discovery of the conspiracy Catesby fled with his fellow-plotters, taking refuge ultimately at Holbeche, Staffs., where on the night of Nov. 8 he was overtaken and killed. He had married Catherine, daughter of Thomas Leigh of Stoneleigh, Warwick, and left a son, Robert, who inherited that part of the family estate which had been settled on Catesby's mother and was untouched by the attainder. Robert is said to have married a daughter of Thomas Percy. (*See* also GUNPOWDER PLOT.)

CAT-FISH, the name generally given to the fishes of the suborder Siluroidea of the order Ostariophysi, in which the air-bladder is connected with the internal ear by a chain of ossicles, probably enabling the fishes to hear well. From the Cyprinoids (characins, carps and electric eels) the Siluroids are distinguished by having the body naked or armoured with bony plates, never normally scaled, and by a number of osteological characters: the air-bladder generally extends laterally so that on each side it is in contact with the skin above the pectoral fin. The name "cat-fish" has reference to the long barbels or feelers about the mouth, of which one pair supported by the maxillaries is always present; generally there are two pairs below the chin, and frequently another developed from the valves between the nostrils. Nearly all the Siluroids are fresh water fishes, but two families are secondarily marine, the Ariidae, found on the coasts and in estuaries of all tropical countries, and the Plotosidae of the Indo-Pacific. The group is a large and varied one, containing probably about 2,000 species belonging to 23 different families; most are omnivorous, feeding on almost any kind of animal or vegetable food, and acting as scavengers. The spines of the dorsal and pectoral fins, which are so generally present, are powerful weapons, capable of inflicting severe and sometimes poisonous wounds.

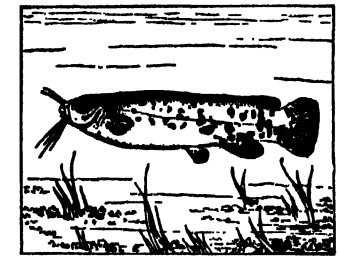
FIG. 1.—CAT-FISH OF NORTH AMERICA, OF THE FAMILY AMIURIDAE

The cat-fishes of North America belong to the family Amiuridae, which is peculiar to that continent, and is known from fresh-water deposits in Wyoming dating from the middle Eocene age. The Amiuridae are closely related to the Bagridae of Africa and Asia, and like them and most Siluroids have a short dorsal fin, with a spine, followed by an adipose fin on the tail. The anterior rays of the pectoral fins are spinous. The head is rather flat, with the mouth terminal and moderately wide, and the jaws with bands of small teeth; there are eight barbels. There are about 25 species, some of which are small; *Amiurus lacustris* of the Great Lakes attains a weight of more than 150 lb. These fishes scoop out a nest in the mud, and the male parent guards the eggs, and later swims with the brood near the shore.



The European cat-fish (*Silurus glanis*), the "Wels" of the Germans, is said to reach a length of 10 ft. and a weight of 400 lb. It has a very long tail, beneath which is the long anal fin. Another species (*Parasilurus aristotelis*) occurs in Greece; the remaining Siluridae are Asiatic. In South and Central America are no less than nine families of Siluroids, all endemic. *Diplomyste* of Chile and Argentina, with toothed maxillary, is the most primitive living Siluroid, but other South American forms are highly specialized. Of the Aspredinidae, *Aspredo batrachus* is remarkable for the way in which the female carries the eggs on the abdomen; these sink into the soft spongy skin and a cup develops round each and then becomes stalked. The Trichomycteridae include *Stegophilus* and *Vandellia*, little slender naked fishes that live parasitically in the gill chambers of other fishes, and are said to enter the urethra of persons bathing, and by distending the short spines with which the gill-covers are armed, to cause inflammation or even death.

Y COURTESY OF THE NEW YORK ZOOLOGICAL OCIETY

FIG. 2.—CAT-FISH OF THE GREAT LAKES, (AMIURUS LACUSTRIS)

The Loricariidae, with about 300 species, are mostly fishes that are covered by a long armour of five series of bony plates on each side, and have the lips expanded into a sucker by means of which they hold on to stones. They feed mainly on mud and algae and have a very long intestine that is coiled like a watch-spring. In some species there are pronounced sexual differences, the males having broader and blunter heads, margined with spines or bristles, or bearing branched tentacles on the snout. In the mountain streams of the Andes the Loricariidae are represented by small forms (*Cyclopium* or *Arges*) known as "prenadillas"; in these regions there are no carnivorous fishes to attack them and they are completely naked, having lost the bony armour that protects the lowland forms. A mining engineer who had diverted a stream in order to empty a pot-hole, observed a number of these fishes climb a precipice from the hole to the stream above it, obtaining alternate holds with the sucker and the rough surface of the pelvic fins; these were moved forward by the contraction of special muscles attached to the pelvic bones, while the sucker was holding. The Callichtyidae are another armoured family, but with only two rows of plates on each side of the body. Callichthys builds nests of grass, sometimes placed in a hole scooped out of the bank; both parents guard the nest. In the South American Doradidae, as in the similar but unrelated Mochochidae of Africa, the air-bladder is a sound-producing organ. *Doras* travels from one pond to another in the dry season, sometimes journeying all night. The Clariidae of Africa and Asia are also air-breathing fishes, provided with air-chambers above the gills; in *Clarias* special vascular tree-like organs nearly fill the chamber, but in *Saccobranchus* these are absent and the air-sac extends backwards for half the length of the fish. These are elongate, more or less eel-shaped fishes; in the dry season they burrow in the mud, but some species are said to leave their burrows at night and crawl about on land in search of food

FROM JORDAN, "FISHES" (D. APPLETON)

FIG. 3.—CAT-FISH OF AFRICA, (MALOPTERURUS ELECTRICUS)

The African Amphiliidae and the Sisoridae of India have the lower surface of the head and abdomen flat and the paired fins horizontal, an adaptation to life in mountain torrents; in some genera the lips form a sucker similar to that of the Loricariidae. The electric cat-fish (*Malopterurus electricus*) is widely distributed in Africa. The skin is soft, and immediately beneath it lies the electric organ, formed of rhomboidal cells of a fine gelatinous substance, and differing from that of other fishes in being part of the tegumentary system, not derived from the muscles. Certain species of *Synodontis*, a genus common in the Nile, are white on the back and blackish beneath, a coloration connected with their habit of swimming belly upwards. The Ariidae,

most of which live in salt water, are typical Siluroids in form and structure of the fins, whereas the other marine family, the Plotosidae, have a very long tail, with the long anal fin confluent with the caudal. In some species of *Arius* the eggs, few in number and as large as marbles, are carried about by the male in his mouth. *Bucklandium* from the lower Eocene (London clay) is an Ariid. (C. T. R.)

CATGUT, the name applied to cord of great toughness and tenacity prepared from the intestines of sheep, or occasionally from those of the horse, mule and ass. Those of the cat are not employed, and therefore it is supposed that the word is properly *kitgut, kit* meaning "fiddle," and that the present form has arisen through confusion with *kit*-cat. The substance is used for the strings of harps and violins, as well as other stringed musical instruments, for hanging the weights of clocks, for bow-strings, and for suturing wounds in surgery. To prepare it the intestines are cleaned, freed from fat, and steeped for some time in water, after which their external membrane is scraped off with a blunt knife. They are then steeped for some time in an alkaline lye, smoothed and equalized by drawing out, subjected to the antiseptic action of the fumes of burning sulphur, if necessary dyed, sorted into sizes, and twisted together into cords of various numbers of strands according to their uses. The best strings for musical instruments are imported from Italy ("Roman strings"), and it is found that lean and ill-fed animals yield the toughest gut.

CATHA, a shrub (*Catha edulis,* family Celastraceae) native to Arabia and to Africa from Abyssinia to the Cape. It is also cultivated, especially in Arabia, where it is called *khat, kat,* or *kasta.*

The Arabians make a kind of tea from the dried leaves and young shoots. These are also chewed extensively for their stimulant properties, which somewhat resemble those of coca.

CATHARS (Cathari or Catharists), a widespread heretical sect of the middle ages. This article relates to the Western Cathars, as they appear (1) in the Cathar Ritual written in Provençal and preserved in a 13th-century ms. in Lyons, published by Clédat, Paris, 1888; (2) in Bernard Gui's *Practica inquisitionis haereticae pravitatis,* edited by Canon C. Douais, Paris, 1886; and (3) in the *procès verbal* of the inquisitors' reports. Some are dualists, and believed that there are two gods or principles, one of good and the other of evil, both eternal; but as a rule they subordinated the evil to the good, and all were universalists in so far as they believed in the ultimate salvation of all men.

Their tenets were as follows:—The evil god, Satan, who inspired the malevolent parts of the Old Testament, is god and lord of this world, of the things that are seen and are temporal, and especially of the outward man which is decaying, of the earthen vessel, of the body of death, of the flesh which takes us captive under the law of sin and desire. This world is the only true purgatory and hell, being the antithesis of the world eternal, of the inward man renewed day by day, of Christ's kingdom which is not of this world. Men are the result of a primal war in heaven, when hosts of angels incited by Satan or Lucifer to revolt were driven out, and were imprisoned in terrestrial bodies created for them by the adversary.

How shall man escape from his prison-house of flesh, and undo the effects of his fall? For mere death brings no liberation, unless a man is become a new creation, a new Adam, as Christ was; unless he has received the gift of the spirit and become a vehicle of the Paraclete. If a man dies unreconciled to God through Christ, he must pass through another cycle of imprisonment in flesh; perhaps in a human, but with equal likelihood in an animal's body. For when after death the powers of the air throng around and persecute, the soul flees into the first lodging of clay that it finds. Christ was a life-giving spirit, and the *boni homines,* the "good men," as the Cathars called themselves, are his ambassadors. They alone have kept the spiritual baptism with fire which Christ instituted, and which has no connection with the water baptism of John; for the latter was an unregenerate soul, who failed to recognize the Christ, a Jew whose mode of baptism with water belongs to the fleeting outward world and is opposed to the kingdom of God.

The Cathars fell into two classes, corresponding to the Baptized and the Catechumens of the early church, namely, the Perfect, who had been "consoled," *i.e.,* had received the gift of the Paraclete; and the *credentes* or Believers. The Perfect formed the ordained priesthood and controlled the church; they received from the Believers unquestioning obedience, and as vessels of election in whom the Holy Spirit already dwelt, they were adored by the faithful, who were taught to prostrate themselves before them whenever they asked for their prayers. They alone were become adopted sons, and so able to use the Lord's Prayer, which begins, "Our Father, which art in heaven." The Perfect alone knew God and could address him in this prayer, the only one they used in their ceremonies. The mere *credens* could at best invoke the living saint, and ask him to pray for him.

All adherents of the sect seem to have kept three Lents in the year, as also to have fasted Mondays, Wednesdays and Fridays of each week; in these fasts a diet of bread and water was usual. But a *credens* under probation for initiation, which lasted at least one and often several years, fasted always. The life of a Perfect was so hard, and, thanks to the inquisitors, so fraught with danger, that most Believers deferred the rite until the death-bed, as in the early centuries many believers deferred baptism. The rule imposed complete chastity. The passages of the New Testament which seem to connive at the married relation were interpreted by the Cathars as spoken in regard of Christ and the church. The Perfect must also leave his father and mother. The family must be sacrificed to the divine kinship. He that loveth father or mother more than Christ is not worthy of him, nor he that loveth more his son or daughter. The Perfect takes up his cross and follows after Christ. He must abstain from all flesh diet except fish. He may not even eat cheese or eggs or milk, for they, like meat, are produced *per viam generationis seu coitus.* Everything that is sexually begotten is impure. Fish were supposed to be born in the water without sexual connection, and on the basis of this old physiological fallacy the Cathars framed their rule of fasting. And there was yet another reason why the Perfect should not eat animals, for a human soul might be imprisoned in its body. Nor might a Perfect or one in course of probation kill anything, for the Mosaic commandment applies to all life.

The central Cathar rite was *consolamentum,* or baptism with the spirit. The spirit received was the Paraclete, the Comforter, derived from God and sent by Christ, who said, "The Father is greater than I." Of a consubstantial Trinity the Cathars naturally had never heard. Infant baptism they rejected because it was unscriptural and because all baptism with water was an appanage of the Jewish demiurge Jehovah, and as such expressly rejected by Christ. The *consolamentum* removes original sin, undoes the effects of the primal fall, clothes upon us our habitation which is from heaven, restores to us the lost garment of immortality. A Consoled is an angel walking in the flesh, whom the thin screen of death alone separates from Christ and the beatific vision. The rite was appointed by Christ, and has been handed down from generation to generation by the *boni homines.*

In the case of a candidate for initiation the Perfect addresses the postulant by the name of Peter; and explains to him from Scripture the indwelling of the spirit in the Perfect, and his adoption as a son by God. The Lord's Prayer is then repeated by the postulant after the elder, who explains it clause by clause. Then came the Renunciation, primitive enough in form, but the postulant solemnly renounced, not Satan and his works and pomp, but the harlot church of the persecutors; he renounced the cross which its priests had signed on him by baptism and other magical rites. Next followed the spiritual baptism itself, consisting of imposition of hands, and holding the Gospel on the postulant's head. The elder begins a fresh allocution by citing Matt. xxviii. 19, Mark xvi. 15, 16, John iii. 3 (where the Cathars' text must originally have omitted in v. 5 the words "of water and," since their presence contradicts their argument). Acts ix. 17, 18, viii. 14–17, are then cited; also John xx. 21–23, Matt. xvi. 18, 19, Matt. xviii. 18–20, for the Perfect one receives in this rite power

to bind and loose. The Perfect's vocation is then defined in terms of a strictly literal observance of the Commandments and the Sermon on the Mount. Asked if he will fulfil these demands, the postulant answers: "I have this will and determination. Pray God for me that he give me his strength." The next episode of the rite exactly reproduces the Roman *confiteor* as it stood in the 2nd century; "the postulant says: '*Parcite nobis*. For all the sins I have committed, in word or thought or deed, I come for pardon to God and to the church and to you all.' And the Christians shall say: 'By God and by us and by the church may they be pardoned thee, and we pray God that he pardon you them.'"

There follows the act of "consoling." The elder takes the Gospel off the white cloth, where it has lain all through the ceremony, and places it on the postulant's head, and the other *boni homines* present place their right hands on his head; they shall say the *parcias* (spare), and thrice the "Let us adore the Father and Son and Holy Spirit," and then pray thus: "Holy Father, welcome thy servant in thy justice and send upon him thy grace and thy holy spirit." Then they repeat the "Let us adore," the Lord's Prayer, and read the Gospel (John i, 1–17). This was the vital part of the whole rite. The *credens* is now a Perfect one; the Perfect ones present give him the kiss of peace, and the rite is over.

The Cathar Eucharist was equally primitive, and is thus described by a contemporary writer in a 13th-century manuscript in the Milan library: "The Benediction of bread is thus performed by the Cathars. They all, men and women, go up to a table and standing up say the 'Our Father,' [as according to St. Gregory (*Ep.* ix, 12–26), was the custom of the apostles]. And he who is prior among them, at the close of the Lord's Prayer, shall take hold of the bread and say: 'Thanks be to the God of our Jesus Christ. May the Spirit be with us all.' And after that he breaks and distributes to all. And such bread is called bread blessed, although no one believes that out of it is made the body of Christ."

CATHARSIS means purification. Since the time of Aristotle the term has been definitely associated with the question of the effects of tragedy on the spectators or on the actors. Aristotle maintained that tragedy and also certain kinds of music tend to purify the spectators and listeners by artistically exciting certain emotions which act as a kind of homeopathic relief from their own selfish passions. Goethe was of opinion that the catharsis affects the actors in the tragedy rather than the spectators or readers. Lessing, on the other hand, held that it affects the spectators and readers rather than the performers. Lessing also maintained that catharsis takes the form of a sublimation of the emotions or their conversion into virtuous dispositions.

BIBLIOGRAPHY.—Butcher, *Aristotle's Theory of Poetry* (1895); J. Bernays, *Zwei Abhandlunger über die Aristotelische Theorie des Dramas* (1880); G. E. Lessing, *Hamburgische Dramaturgie* (1769, etc.).

CATHARTIC, an agent used to relieve constipation. Aperients, laxatives, cathartics, eccoprotics, purgatives, physics, hydragogues and drastics, arranged in order of intensity, differ only in the degree to which they act. Cathartic action depends usually upon increased fluidity or bulk of the gut contents or upon irritation of the gut. Cathartics include: (1) saline cathartics such as sodium and magnesium sulphate, poorly absorbable salts that hold water in the gut by osmotic force; (2) bulk producers such as psyllium seeds and agar which take up water and swell, and bran which contains a high proportion of insoluble material; (3) emollients such as mineral oil which is poorly absorbed and coats the intestinal wall with an oily film, preventing the absorption of water; (4) irritant oils such as castor oil and croton oil; (5) anthracene derivatives such as senna, rhubarb, cascara and aloe which owe their activity to various polyhydroxyanthroquinones, present usually as glucosides; (6) the cathartic resins such as euphorbium, jalap, podophyllum, elaterium, gamboge and colocynth in which the active ingredient is usually a glucoresin; (7) miscellaneous irritants such as phenolphthalein and mercurous chloride (calomel).

Cathartics have been exploited by the patent-medicine industry probably more than any other group of drugs. Many cases of chronic constipation have resulted from their indiscriminate use. They should be taken only upon the advice of a physician since serious harm can result from an attempt to relieve gastrointestinal symptoms without knowing their cause.

CATHARTIDAE: *see* VULTURE.

CATHAY, the name by which China became known to mediaeval Europe. It is derived from Khitai, the name of the kingdom of Khitan Tatars (10th and 11th centuries A.D.) which, based on Manchuria (the northeastern gateway into China), included at times part of northern China as well and which toward its close had its capital at Yenking (Kublai Khan's Cambaluc, *q.v.*, and the modern Peking). The central Asian Tatars, in touch only with its northern territories, knew China by this name and the Russians through contact with them introduced it into Europe. The Russians and the peoples of central Asia still know China as Khitai or Kitai. Although in Marco Polo's time all China was under the control of the Great Khan, he limits Cathay to the country north of the Yangtze valley, calling southern China by the separate name of Mangi. The distinction was at that time a real one, since Mangi retained the old Sung culture practically undiluted while Cathay bore the impress of the Tatar conquest. In the 16th century, however, when European navigators reached far eastern waters via the Spice Islands it was Mangi which they knew as China (this name is thought to have been derived by neighbouring peoples from the Chin dynasty, 3rd century B.C., but is not found in the Chinese language); and Cathay was understood to lie away to the north of it and to be reached by a still undiscovered sea route. Hence ensued the search for the northwest and northeast passages from Europe. This dualism corresponds to the distinction apparent in Roman literature between the Seres—the Chinese as approached by the overland route—and the Sinae—the Chinese as approached by the sea route from the south. Only in the early 17th century was the identity of the country and of the people reached by the two routes appreciated.

CATHCART, the name of a family of Scottish, and from 1807 of British, peers, of whom the following are historically most important:

WILLIAM SCHAW CATHCART, 1ST EARL (1755–1843), was born at Petersham, Sept. 17, 1755. Leaving Eton in 1771, he went to St. Petersburg, where his father, the 9th Baron Cathcart (1721–76), was ambassador. He succeeded to the barony in 1776 and, having studied law at Dresden and Glasgow, was admitted to the Scottish faculty of advocates. In 1777 he joined the army and commanded troops in America, the Netherlands and Germany. He later served as commander in chief in Ireland (1803–05), and led the British expedition to Hanover (1805). In 1806 he was sent on a diplomatic mission to Russia and in 1807 commanded the land forces in the Copenhagen expedition. After the capture of Copenhagen he was created Viscount Cathcart of Cathcart and Baron Greenwich of Greenwich. He was promoted general in 1812. In July of the same year he was appointed ambassador and military commissioner in Russia, where he remained until 1820. He was created earl in 1814. He died at his estate near Glasgow, June 16, 1843.

CHARLES MURRAY CATHCART, 2ND EARL (1783–1859), eldest son of the above, succeeded to the title in 1843. He saw distinguished service in the Napoleonic wars and was commander in chief in Canada from 1846 to 1849. Cathcart's interest in science led to his discovery in 1841 of a new mineral which was named greenockite.

SIR GEORGE CATHCART (1794–1854), third surviving son of the 1st earl, served in the Napoleonic campaigns of 1812–15 and in 1846 became deputy lieutenant of the Tower of London. In 1852 he was made governor of the Cape, where he completed Sir Harry Smith's task of subduing the Kaffirs. In 1854 he returned

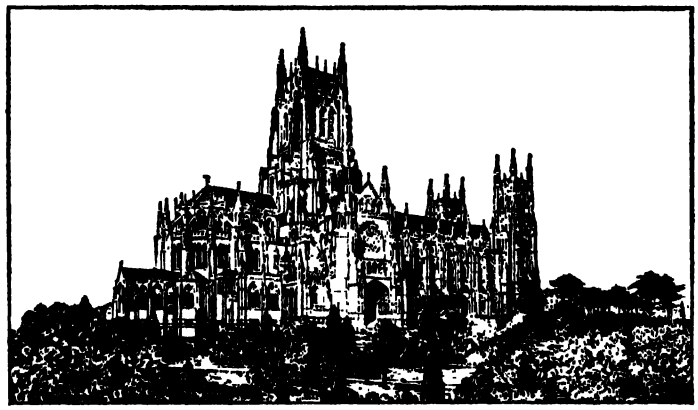
to England and was sent to the Crimea in command of a division. He was killed at the battle of Inkerman.

CATHEDRAL (from Greek *καθέδρα*, Latin *cathedra*, chair or throne) is an adjective frequently used as a noun to mean a cathedral church (*ecclesia cathedralis*); that is, a church in which a bishop has his official seat (*sedes*) or throne.

Early Organization.—A cathedral church is not necessarily a large church, but from the 4th century was supposed to be in a town, not in a village. In Britain in the age of conversion this was not usually possible because there were practically no towns, but after the Norman conquest a number of English cathedrals were moved from villages to the most important town in the diocese. Occasionally two churches jointly share the distinction of containing the bishop's *cathedra* and are therefore said to be con-cathedral in relation to each other. Examples are in Ireland at Christ church and St. Patrick's, Dublin, and in England before the Reformation at Bath and Wells and at Coventry and Lichfield. Cathedral churches are of different degrees of dignity: the simple cathedral church of a diocesan bishop; the metropolitical church to which other diocesan cathedral churches of a province are suffragan; the primatial church under which are metropolitical churches and their provinces; patriarchal churches to which primatial, metropolitical and simple cathedral churches alike owe allegiance. The title "primate" was occasionally conferred on metropolitans of sees of dignity and importance, such as Canterbury, York and Rouen, whose cathedral churches remained simply metropolitical.

The bishop by canon law was pastor of his cathedral church, which was the mother church (*matrix ecclesia*) of his diocese or, as it was called in early times, parish (*parochia*), a word used later for the parishes into which the diocese was divided. His cathedral clergy, which included priests, deacons, subdeacons and clerks in minor orders, originally formed his *familia* or household and lived a communal life with him, sharing the common goods of the church and helping to serve its large parish. They were not usually monks, but their communities were often described as *monasteria*, a word which then had a less restricted meaning than it later acquired. Because of this, churches such as York and Lincoln, which never had monks attached to them, inherited the name minster or monastery. In time the common life was abandoned and the clergy lived in separate houses, but in the 8th and early 9th centuries the revival of the common life in a stricter form was advocated by reformers in the Carolingian empire, chiefly as a means of enforcing celibacy among cathedral clergy. The most famous and successful rule for cathedral clergy at this time was that of Bishop Chrodegang of Metz, written about 755. It was based largely on the Benedictine rule, but was less strict in requirements for individual poverty. At the council of Aix-la-Chapelle, 817, it was chosen as the basis for a widespread adoption of a common life at cathedral and collegiate churches throughout the empire. In England it was introduced at Canterbury for a short time about 813, and at several other cathedral churches in the 11th century, before the Norman conquest. The clergy who followed it were called canons or canonical clerks because they observed a definite rule or canon (from Greek *κανών*, rule).

Secular and Regular Cathedrals.—From the 10th century two increasingly divergent movements can be traced in the history of the organization of communities of canons. On the one hand, attempts to enforce the common life met with more resistance and, in times of invasions, with unrest and relaxation of ecclesiastical discipline, many cathedral canons acquired private property, lived in separate houses and divided a large part of the common estates and goods of their church into separate portions or prebends (provender) for themselves. Because of these separate possessions they were called "secular" canons. This division of common goods was recognized as permissible on the continent about the middle of the 11th century. However, this "secularizing" movement led, in the religious revival of the same period, to a renewed demand for clergy to live the communal apostolic life and, as a result, in the early 12th century many communities of canons adopted a strict form of common life under the rule of St. Augustine. They were called "regular" (from Latin *regula*, rule) or Augustinian canons, and their life soon became barely distinguishable from that of Benedictine monks. From this time cathedral churches were normally organized on either a regular or a secular basis. On the greater part of the continent the regular cathedrals of the middle ages were served by Augustinian or Premonstratensian canons, though in parts of Germany and in Denmark some were served by Benedictine monks. In England the 10th-century monastic revival had resulted in the introduction of Benedictine monks to serve three or four cathedrals, and in the ecclesiastical reorganization following the Norman conquest these were increased to nine—Canterbury, Winchester, Worcester, Rochester, Bath, Coventry, Ely, Norwich, Durham; that is, nearly half the total number of English mediaeval cathedrals. In Ireland at Downpatrick and in Sicily at Monreale, Benedictine cathedral chapters were also founded in the late 12th century under Anglo-Norman influence. England had only one Augustinian cathedral, Carlisle, founded in 1133. Christ church, Dublin, in Ireland and St. Andrews in Scotland were Augustinian, while Whithorn, the cathedral church of Galloway, was Premonstratensian. All the other mediaeval cathedrals of Britain gradually became secular in the period following the Norman conquest. A secular organization was first introduced at Salisbury, Lincoln, York and London about 1089–91, and later spread to Wells, Lichfield, Chichester, Hereford and Exeter in England and to Elgin (Moray), Glasgow and Aberdeen in Scotland.



Neither in the regular nor secular mediaeval cathedrals was the early intimate association of bishop and cathedral clergy maintained. With the end of the missionary period of conversion and with the formation of parishes, the cathedral church lost its parochial character, and the interests of its clergy became centred in its services and government, while the bishop was increasingly drawn away on diocesan duties or affairs of state. The cathedral chapters always kept certain links with their bishop and diocese. They continued to act as permanent trustees of episcopal property; their consent was necessary to episcopal acts which involved financial arrangements of the church and see; they sometimes exercised episcopal jurisdiction in a vacancy of a see and in 1215 were recognized as having the sole right to elect their bishop. But from the 11th or 12th century most cathedral chapters controlled their own property, which was separate from that of the bishop, and assumed, especially in northern France and England, the position of independent corporations, jealous of their rights and privileges. Mediaeval English bishops were often afraid to adventure themselves in their cathedral cities for fear of conflicts with their chapters. In the regular chapters the bishop was in the position of titular abbot, but attempts by him to act as abbot were quickly resented. The convent of regular canons or monks formed the chapter, of which the prior was head, and its constitution and way of life was ordered by the Benedictine or Augustinian rule.

The constitutions of the secular cathedral chapters showed greater variety. Their two main characteristics were separate prebendal incomes for the canons and a system of home government at the cathedral based on a varying number of dignitaries, who divided the administrative work between them and were supposed to be continuously resident. The prebends were of varying value, but many were sufficient to enable canons to be nonresident and do work at a distance from the cathedral in the rapidly expanding administrations of kings, popes, archbishops and bishops, in the growing schools of the 12th century and in the universities of the 13th century. Nonresidence was soon regarded as lawful, for a canonry, unlike a dignity, was without cure of souls. Nonresident canons, however, were forbidden to share in the chapter's common fund, which was kept for the residentiaries, who bore the "heat and burden of the day" at the cathedral. By the 14th century in England secular cathedral canons were usually fairly clearly divided into two groups, residentiaries and nonresidentiaries, and the residentiaries might form about a quarter of the full body of 21 to 54 canons. By the 16th and 17th centuries, because of the increase in the common fund and the reduction of the residentiaries to a small fixed number of five to nine, residence at these cathedrals had become a privilege to which nonresident prebendaries eagerly awaited election, and government was almost entirely vested in the small inner chapter of residentiaries.

In England the constitutions of the nine mediaeval secular cathedrals became in the course of the 12th, 13th and 14th centuries remarkably homogeneous. They have been described as four square, because they

EXAMPLES OF CATHEDRAL ARCHITECTURE FROM THE 11TH TO THE 20TH CENTURY

Although a cathedral is usually large, a small building can serve, as in the case of the tiny cathedral at Athens. Salisbury and Beauvais cathedrals represent English and French phases of Gothic; that of Seville shows the Spanish late-Gothic-Renaissance transitional style; the curious St. Basil's cathedral, Moscow, combines Byzantine and Italian Renaissance features with Russian timber-church and tartar motifs and purely fanciful elements; and Westminster cathedral (Roman Catholic) and the cathedral of St. John the Divine are modern adaptations of Byzantine and Gothic precedents

were based on four great dignitaries who normally occupied the four terminal stalls in choir. The dean was president of the chapter and had cure of souls of all the cathedral clergy; the precentor was in charge of the music, liturgy and song school; the chancellor was the chapter's secretary and supervised the cathedral schools of grammar and theology; the treasurer guarded the church's treasures and provided lights and other material necessaries for the services. Under these were various deputies and officers, such as a subdean, succentor, vice-chancellor, grammar master, lecturer in theology, subtreasurer and sacrists, with masters or wardens of the fabric and common funds, some of whom were canons while others were vicars choral or chantry chaplains. Vicars choral were appointed from the 12th century not only by nonresident but also by residentiary canons, and corresponded to the *heuriers, matiniers* and demiprebendaries of some French chapters, whose chief duties were to sing the services. By the later middle ages they were in effect the working staffs of the cathedrals and formed minor self-governing corporations under the wealthy controlling corporation of the chapter.

English and Continental Development.—The English cathedral constitutions in their origins at the end of the 11th century can have been derived only from cathedrals of Normandy or northern France, where similar dignitaries then performed roughly similar functions, though their numbers, status and precedence still varied and were unfixed, and no one Norman cathedral provided an exact model. The remarkable similarity of the English constitutions of the later middle ages seems, however, to have been the result not merely of a common origin or imitation of a Norman model, but also of independent development in England in the 12th and 13th centuries and of the growing practice by English chapters of borrowing and adopting each others' customs, particularly those of Salisbury. On the continent there was far greater diversity in constitutions and titles, of which Chartres, with dignitaries in the 14th century, or Milan, with an archpriest at the head of the chapter, archdeacon and four *primicerii,* are particularly good examples. Generally it seems that the strong independent chapter with a dean as sole head under the bishop developed first in northern France about the 10th and 11th centuries. Elsewhere about this time there was often a division between the spiritual authority in the chapter, exercised usually by a dean in Germany and the Low Countries and by an archpriest in southern France and Italy, and the temporal authority of a provost or archdeacon, who administered the capitular estates. In Germany, Scandinavia and parts of eastern and southern France the provost often later emerged as sole head of the chapter, while in Italy about half the cathedrals came to have an archdeacon at their head.

In France most of the regular cathedral chapters were secularized about the time of the Reformation. In England Henry VIII dissolved the monastic cathedral chapters and, except for Bath and Coventry, refounded them as secular chapters under a dean with an organization suggested by that of English colleges of resident chantry priests in the later middle ages. These are called cathedrals of the New Foundation. He also founded six new cathedrals with similar constitutions in churches of dissolved monasteries at Bristol, Chester, Gloucester, Oxford, Peterborough and, for a time, Westminster. The nine mediaeval secular cathedrals, known as cathedrals of the Old Foundation, survived the Reformation with their constitutions practically unchanged; they underwent drastic changes and the loss of their prebendal estates by the Cathedrals act, 1840. Since 1836 3 ancient English collegiate churches, Ripon, Manchester and Southwell, and 18 parish churches (including the originally monastic churches of St. Albans and Southwark) have been converted into cathedrals of new dioceses, while new cathedrals have been built at Truro, Liverpool and Guildford.

Architecture.—The architectural history of the west European cathedral begins with the first large Christian basilicas—old St. Peter's and others—built in Rome soon after Constantine's edict of 323. The long colonnaded nave drew the worshipper's attention irresistibly to the eastern apse where stood the main altar and, behind that, the bishop's throne, later moved to a chancel between apse and nave. In the metropolitan churches, though not usually those of other cities, this eastward drive was checked by the intrusion of a large transverse space called *bema,* forerunner of the mediaeval transept and serving both to give room for ceremonial deployment before the altar and to withdraw the mystical focus of the church a little from the congregation. In later centuries this longitudinal and apsidal plan continued in use, with modifications, for many cathedrals and abbey churches (it is impossible to isolate the development of strictly "cathedral" buildings); the cathedral of S. Apollinare in Classe, Ravenna (534–539), was of this type, as was such a Carolingian abbey as Fulda (begun 802).

Hardly any of the typical features of the French High Gothic cathedral would have been possible without preliminary development in the Romanesque period (*c.* 1000–1200). Thus the cluster of apsidal chapels jutting from a passage or ambulatory laid round the main apse—chapels made necessary by increasing worship of saints and the growing custom of each canon saying Mass daily—is traceable at least to St. Martin at Tours of 997–1020; Durham had rib vaults, Nevers (Burgundy) a form of flying buttress and Autun (in the same province) pointed arcades almost half a century before the rebuilding of St. Denis abbey, 1137–44, as the first of the large true Gothic churches of the Île de France. But in the High Gothic cathedral these features developed rapidly: nave vaulting (rediscovered in early Romanesque times to replace the inflammable flat timber roof of the basilicas) was lightened and carried to ever greater heights; translucent glass displaced solid stone wall. The eastward drive of the Early Christian church was replaced by an upward drive: Romanesque Durham was 80 ft. high to the crown of its vaults; Notre Dame, Paris (1163–1208) reached 115 ft.; Beauvais (1272) 157 ft. (but after later partial collapse remains a truncated naveless folly).

By comparison the English mediaeval cathedral is of modest proportions, long and low; set within a cloistered precinct proclaiming its monastic or collegiate origin (viz., Canterbury), not jutting up directly from the street; entered through a quiet north porch rather than the spectacular western figure portals of the Île de France. English west fronts, however, often had an impressive program of sculpture, as at Wells, Exeter and elsewhere.

The imagination of the Renaissance humanist-architect was captured anew by the aesthetic possibilities of the "central" plan; of a cathedral centrally domed and symmetrically disposed north, south, east and west—a plan fairly common in earlier times (St. Sophia, Constantinople, and S. Vitale, Ravenna, in the 6th century; Aachen cathedral of the 9th; St. Mark's, Venice, in the 12th). Bramante and Michelangelo proposed completely symmetrical plans for the rebuilding of St. Peter's at the end of the 16th century, but the traditional needs of the church compelled Carlo Maderna to add a long western nave when he completed the cathedral after 1600. Sir Christopher Wren was faced with a similar difficulty and forced to a similar modification in the rebuilding of St. Paul's cathedral, London (1675–1710).

Neither the 19th century nor the modern architectural movement beginning in the 1880s produced a special cathedral style. Most architects freely adapted historical styles such as the Byzantine (Westminster cathedral, J. F. Bentley, 1896 *et seq.*) and Gothic (Liverpool, Sir G. G. Scott, 1903 *et seq.*, and the remodelled St. John the Divine, New York city, R. A. Cram and F. W. Ferguson, 1910 *et seq.*). However, in his designs for the new Coventry cathedral (approved 1951, modified 1952–53) B. Spence mainly rejected traditional architectural styles and used tent forms, facet vaulting and other new features. CATHELINEAU, JACQUES (1759–1793), French Vendean chieftain during the Revolution, was born on Jan. 5, 1759, at Tin-en-Manges, Maine-et-Loire. In the first years of the Revolution, Cathelineau listened to the exhortations of Catholic priests and royalist *émigrés* and joined the insurrection provoked by them against the revolutionary government. Collecting a band of peasants and smugglers, he took the château of Gallais, where he captured a cannon, christened by the Vendeans the "Missionary"; he then took the towns of Chemillé, Cholet, Vihiers and Chalonnes (March 1793). His companions committed atrocities which brought upon them terrible reprisals on the part of the Republicans. Meanwhile Cathelineau's troops increased, and he combined with the other Vendean chiefs, such as N. Stofflet and M. L. J. Gigot d'Elbée, taking the towns of Beaupréau, Fontenay and Saumur. The first successes of the Vendeans were a result of the fact that the Republicans had not expected an insurrection. When the resistance to the insurgents became more serious differences arose among their leaders. To avoid these rivalries, it is thought that Cathelineau was named generalissimo of the rebels, though his authority over the undisciplined troops was not increased by the new office. In 1793 all the Royalist forces tried to capture Nantes. Cathelineau entered the town in spite of the resistance of Gen. J. B. Clanclaux,

but he was killed and the Vendean army broke up. Numerous relatives of Cathelineau also perished in the war of La Vendée. (*See* also CHOUANS; VENDÉE, WARS OF THE.)

CATHER, WILLA SIBERT (1873–1947), U.S. author, was born at Winchester, Va., and as a child of eight or nine was taken to a Nebraska ranch.

After her graduation from the University of Nebraska in 1895, she taught high school English, worked on the Pittsburgh *Leader* and travelled widely. Her first volume of stories, *The Troll Garden* (1905), led to an appointment as associate editor of *McClure's Magazine* (1906–12), which was then a vigorous periodical, a pioneer in the field of magazine journalism, less dignified than the old monthlies, but alive with the spirit of reform and direct appeal to an ever-increasing audience more interested in substance than in form. Miss Cather's first distinguished work in pure literature was *O Pioneers!* (1913), in which, on Sarah Orne Jewett's advice, she endeavoured to recapture "in memory, people and places" which she believed to be forgotten. With it she put herself in the forefront of those who had begun to realize the importance of pioneer life in America. *My Antonia* (1918) was another book with the same general background, which established her reputation as a novelist of unusual depth and power of beauty, who could see deep currents of emotion running in those Main Streets and prairies which Sinclair Lewis was to satirize for their decline into dullness. In *One of Ours* (1922), she stepped aside, not altogether successfully, to tell a story of a western boy in World War I. This novel was awarded a Pulitzer prize. *The Song of the Lark* (1915) was another pioneer story; *A Lost Lady* (1923) was also told against a prairie background, but its simplicity of telling, its depth of tragedy and fineness of insight into the secret and the weakness of woman's charm far outweigh the interest of its local colour. In *The Professor's House* (1925), she began experiments with a new technique of story-telling, constructing her story of an intellectual's soul development according to the familiar methods of music. In *Death Comes for the Archbishop* (1927), she told in the form of a chronicle a simple and vivid story of two saints of the southwest. This, *A Lost Lady, Shadows on the Rock* (1931), and *Lucy Gayheart* (1935) are her best books. Her short stories in the collection *Youth and the Bright Medusa* (1920) escape the stereotyping that has devitalized so many U.S. short-story writers. Her first book was in verse, *April Twilights* (1903); her first novel, *Alexander's Bridge* (1912). Among the writers who in the early 20th century deepened and refined the study of American character, Willa Cather was perhaps pre-eminent. Her style is restrained, sometimes almost cold, but rising into passages of great beauty, and always in harmony with her subject. Her themes are broader and more human than Edith Wharton's; her analysis of human motives deeper than Booth Tarkington's; and she was perhaps closer to essential Americanism in its spiritual and emotional aspects than any other contemporary writer. She is not rich in humour, nor pointed in satire, and in this differed from her nearest contemporaries, but she came closest in U.S. literature of this period to the classic ideal of balance, insight, restraint. She died April 24, 1947, in New York city.

See articles on her work by T. K. Whipple in *Spokesmen: Modern Writers and American Life;* A. Porterfield, *Contemporary American Authors*, edited by J. C. Squire; Elizabeth S. Sergeant, *Fire Under the Andes* (1927). (H. S. C.)

CATHERINE, SAINT. The Roman hagiology contains seven saints of this name. 1. ST. CATHERINE OF ALEXANDRIA, virgin and martyr, whose day of commemoration recurs on Nov. 25. 2. ST. CATHERINE OF SIENA, 1347–80, Dominican tertiary whose feast is observed on April 30. 3. ST. CATHERINE OF SWEDEN, daughter of St. Bridget, who died abbess of Vadstena in 1381, and is commemorated on March 22. 4. ST. CATHERINE OF BOLOGNA, 1413–63, abbess of the Poor Clares in Bologna, canonized by Pope Clement XI, and mentioned in the Roman Martyrology on March 9. 5. ST. CATHERINE OF GENOA (1447–1510), who belonged to the noble family of Fieschi, devoted her life to the sick, especially during the plague at Genoa in 1497 and 1501. She was beatified by Clement X in 1675 and canonized by Clement XII in 1737, her feast being on July 22. *See* F. von Hügel, *The Mystical Element in Religion as studied in St. Catherine of Genoa*, 2nd ed. (1923). 6. ST. CATHERINE DE' RICCI, of Florence (1522–1590), became a Dominican nun at Prato. She was famous during her lifetime for the weekly ecstasy of the Passion, during which she experienced the sufferings of the Holy Virgin contemplating the Passion of her Son. She was canonized in 1746 by Benedict XIV, who fixed her festal day on Feb. 13. In Celtic and English martyrologies (Nov. 25) there is also commemorated St. Catherine Audley (*c.* 1400), a recluse of Ledbury, Hereford. Pius XI in 1930 canonized ST. CATHERINE TOMÀS (d. 1574), of Majorca.

Of the first two saints something more must be said. Of St. Catherine of Alexandria, history has little to tell. According to the legend recorded in the Roman martyrology, and in Simeon Metaphrastes, Catherine upbraided the Emperor Maximinus for his cruelties, and adjured him to give up the worship of false gods. The angry tyrant, unable to refute her arguments, sent for pagan scholars to argue with her, but they were discomfited. Catherine was then scourged and imprisoned. When the empress went to reason with her, Catherine converted her as well as the Roman general and his soldiers, who had accompanied her. Maximinus now ordered her to be broken on the wheel; but the wheel was shattered by her touch. The axe proved fatal, and the martyr's body was borne by angels to Mt. Sinai, where Justinian I. built the famous monastery in her honour. Another variation of the legend is that in which, having rejected many offers of marriage, she was taken to Heaven in vision and betrothed to Christ by the Virgin Mary.

Of these marvellous incidents very little, by the universal admission of Catholic scholars, has survived the test of modern criticism, though her actual existence is generally admitted. In the middle ages she was a most popular saint, her festival being, in certain dioceses of France, a holy day of obligation even as late as the 17th century. The wheel being her symbol, she was the patron saint of wheelwrights and mechanics, as well as the tutelary saint of nuns and maidens, and of philosophers.

St. Catherine of Siena, the youngest daughter of a dyer, was born on March 25, 1347. At an early age she began to practise asceticism and see visions, and when seven dedicated her virginity to Christ. In 1363 she became a Dominican tertiary, and renewed in her home the life of the anchorites in the desert. She resumed family life in 1366 when she began to tend the sick and the poor. Her peculiarities excited suspicion, and charges seem to have been brought against her by some of the Dominicans, to answer which she went to Florence in 1374, soon returning to Siena to tend the plague-stricken. At the invitation of the ruler of Pisa she visited that city in 1375 to arouse enthusiasm for the proposed crusade, and to prevent Pisa and Lucca joining the Tuscan league against the pope. Fra Raimondo relates that, after an ecstasy at Pisa, she told him she had received the *stigmata*, or imprint of the wounds of the crucified Christ, but by her prayer the marks were made invisible. In 1376, Catherine resolved to bring back Pope Gregory XI. from Avignon, attempting first by correspondence to reconcile Gregory and the Florentines, who had been placed under an interdict, and then going in person as the representative of the latter to Avignon. Gregory empowered her to treat for peace, but the Florentine ambassadors proved faithless. Catherine, however, was able to persuade the pope to return to Genoa and then to push on to Rome. There he found life very difficult, and in 1378 sent Catherine on an embassy to Florence, especially to the Guelph party. While she was urging the citizens to make peace with the pope there came the news of his death. During the troubles that ensued in Florence, Catherine nearly lost her life, and sorely regretted not winning her heart's desire, "the red rose of martyrdom." Peace was signed with the new pope, Urban VI., and Catherine, having accomplished her second great political task, went home to Siena. Thence on the outbreak of the schism Urban summoned her to Rome, where she quelled the revolt of the people and tried to win for Urban the support of Europe.

Under the great strain, she died on April 29, 1380, and was canonized by Pius II. in 1461.

Catherine lived on in her writings and disciples. Among the latter were her confessor and biographer, Fra Raimondo, later master-general of the Dominicans, William Flete, an ascetically-minded Cambridge man, Stephano Maconi, who became prior-general of the Carthusians, and the two secretaries, Neri di Landoccio and Francesco Malavolti. The last of her band of reformers, Tommaso Caffarini, died in 1434, but the work was taken up by Savonarola. Catherine's writings consist of: (1) a dialogue entitled, *The Book of Divine Doctrine, given in person by God the Father, speaking to the mind of the most glorious and holy virgin Catherine of Siena, and written down as she dictated it in the vulgar tongue, she being the while entranced, and actually hearing what God spoke in her.* The book has a significant place in the history of Italian literature. "In a language which is singularly poor in mystical works it stands with the *Divina Commedia* as one of the two supreme attempts to express the eternal in the symbolism of a day, to paint the union of the soul with the suprasensible while still imprisoned in the flesh." (2) The prayers (26 in all) which are mostly mystical outpourings. (3) Letters, nearly 400, addressed to kings, popes, cardinals, bishops, conventual bodies, political corporations and individuals. By their historical importance, their spiritual fragrance, their literary value, and their beautiful Tuscan vernacular, the letters put their author almost on a level with Petrarch.

AFTER A WOODCUT FROM "CATHARINA DA SIENA," 1500
ST. CATHERINE OF SIENA

BIBLIOGRAPHY.—*Acta Sanctorum* XII, pp. 861–986, contains the *Vita* of Fra Raimondo; *The Little Flowers of St. Catherine of Siena*, collected by Innocenzo Taurisano, tr. by Charlotte Dease, presents selections from the important sources, the *Vita*, the *Processus* (early testimonies of her followers), the *Miracoli*, the *Supplementum* and three of the saint's letters; *L'Opere*, ed. Girolamo Gigli (Rome 1866); J. Joergensen, *Life of St. Catherine of Siena* (1938); V. D. Scudder, *St. Catherine as seen in her Letters* (1905).

CATHERINE I. (1683–1727), empress of Russia, was the daughter of a Lithuanian peasant named Skavronsky, who died when she was a child. Martha Skavronskaya became a servant in the home of Pastor Glück, the Protestant superintendent of the Marienburg district, and married a Swedish dragoon called Johan. When the Swedes evacuated Marienburg, Martha became one of the prisoners of war of Marshal Sheremetev, who sold her to Prince Menshikov, at whose house, Peter the Great became her lover. After the birth of their first daughter Catherine, Martha was received into the Orthodox Church, when she was rechristened under the name of Catherine Alexeyevna, the tsarevich Alexius being her godfather. She received the title *Gosudaruinya* or sovereign (1710), and Peter, who had divorced the tsaritsa Eudoxia, married her in 1711. Henceforth the new tsaritsa was her husband's inseparable companion. She was with him during the campaign of the Pruth, and Peter always attributed the successful issue of that disastrous war to her courage and sang-froid. She was with him, too, during his earlier Caspian campaigns. He was devoted to her, and she was able to act as a buffer between the tsar and his advisers in his frequent accesses of rage.

By the *ukaz* of 1722 Catherine was proclaimed Peter's successor, to the exclusion of the grand-duke Peter, the only son of the tsarevich Alexius, and on May 7, 1724, was solemnly crowned empress-consort in the Uspensky cathedral at Moscow, on which occasion she wore a crown studded with no fewer than 2,564 precious stones, surmounted by a ruby, as large as a pigeon's egg, supporting a cross of brilliants. Within a few months of her coronation a dangerously familiar flirtation with her gentleman of the chamber, William Mons, caused some scandal. Mons was decapitated and his severed head, preserved in spirits, was placed in the apartments of the empress, but she attended Peter during his last illness, and closed his eyes when he died (Jan. 28, 1725). She was at once raised to the throne by the party of Prince Menshikov and Count Tolstoy with the support of the Guards.

The great administrative innovation of Catherine's reign was the establishment of the *Verkhovny Tainy Sovyet*, or supreme privy council. The executive power was thus concentrated in the hands of a few persons, mainly of the party of Reform (*ukaz* of Feb. 26, 1726). The foreign policy of Catherine I. was principally directed by the astute Andrei Ostermann. Russia now found herself opposed to England, chiefly because Catherine protected Charles Frederick, duke of Holstein, and George I. found that the Schleswig-Holstein question might be reopened to the detriment of his Hanoverian possessions. In the spring of 1726, an English squadron was sent to the Baltic and cast anchor before Reval. The empress protested, and the fleet was withdrawn, but on Aug. 6 Catherine acceded to the anti-English Austro-Spanish league. Catherine died on May 16, 1727. Though quite illiterate, she was an uncommonly shrewd, sensible and good-tempered woman. Her personal extravagance was a byword.

See the authorities referred to *s.v.* PETER I.

CATHERINE II. (1729–1796), empress of Russia, known as CATHERINE THE GREAT, was the daughter of Christian Augustus, prince of Anhalt-Zerbst, and his wife, Johanna Elizabeth of Holstein-Gottorp. She was born at Stettin on May 2, 1729. Her baptismal name was Sophia Augusta Frederica. In 1744 she was taken to Russia, to be affianced to the grand-duke Peter (afterwards Peter III.), the nephew of the empress Elizabeth, and her recognized heir. Frederick the Great favoured the alliance, his object being to strengthen the friendship between Prussia and Russia, to weaken the influence of Austria and to ruin the chancellor Bestuzhev, who was a known partisan of the Austrian alliance. The diplomatic intrigue failed, but Elizabeth took a strong liking to Sophia, and the marriage was finally decided on. On June 28, 1744, she was received into the Orthodox Church at Moscow, and was renamed Catherine Alexeyevna. On the 29th she was formally betrothed, and was married on Aug. 21, 1745 at St. Petersburg. Her married life was wretched. Peter was subnormal in physique and in mind, and his wife despised him. She was a clever and ambitious girl, and was determined that nothing should stand in the way of her ambitions. She accepted the conditions of her marriage because it was the means to power. During the 17 years of her life as grand-duchess she matured her mind and avoided a breach with Elizabeth. For ten years the marriage was barren, and the only reason for supposing that the future tsar Paul, who was born on Oct. 2, 1754, was the son of Peter, is the strong similarity of their characters. Catherine had many lovers. The scandalous chronicle of her life was the commonplace of all Europe. Her most trusted agents while she was still grand-duchess, and her chief ministers when she became empress, were also her lovers.

The Empress Elizabeth died on Jan. 5, 1762. The grand-duke succeeded without opposition as Peter III. He committed every possible folly, grovelled before Frederick the Great, insulted the Church, and threatened to divorce Catherine. She refrained from open opposition and acted with the political prudence which she had shown as grand-duchess. In July Peter foolishly retired with his Holsteiners to Oranienbaum, leaving his wife at St. Petersburg. On the 13th and 14th of that month, a "pronunciamiento" of the regiments of the guard removed him from the throne and made Catherine empress. She issued a manifesto in which she claimed to stand for the defence of Orthodoxy, and the glory of Russia. The guards were manipulated by the four Orlov brothers. The eldest, Gregory, was her recognized chief lover, and he was associated with his brother Alexis in the office of favourite. But the hatred felt for Peter III. was spontaneous, and Catherine had no need to do more than let it be known that she was prepared to profit by her husband's downfall. Peter was sent to a country

house at Ropcha, where he died on July 17 in the course of a scuffle during dinner. His custodian, Alexis Orlov, said he could not remember what happened. Catherine in a second manifesto said she had accepted the throne for the good of the country and remarked that autocracy was a danger if the ruler lacked the requisite qualities.

Catherine the Great ruled Russia for 34 years. Although born a German princess she identified herself completely with the Russian people. She was in the truest sense the successor of Peter the Great. Her private life was the object of unceasing curiosity and interest among her contemporaries, and a mass of literature has grown up around the subject of her lovers and her relations with them. Catherine was never dominated by her lovers who were the instruments of her policy; it was she who governed Russia, not her favourites. Her main interests were intellectual and political, and her love affairs subsidiary. She was the disciple and friend of the Encyclopaedists, especially of Voltaire, the reading of whose works had first awakened her mind. She corresponded with him, with D'Alembert, and, more voluminously, with F. M. Grimm, who spent nearly a year at her court in 1777–78. Grimm reports that her conversation was even more brilliant than her letters. Catherine also corresponded at intervals with Frederick the Great and with Joseph II. Her letters are graceful and witty, and they show real political and diplomatic insight. She was determined to make Russian society as cultivated as the society of Paris and Berlin. At court she insisted on a high standard of decorum and of manners, she encouraged the nobles to travel, and fostered the love of French culture. She herself employed Grimm and others to collect works of art and antiquities for her, and practised sculpture and painting herself. She had a passion for reading, made a digest of Blackstone's *Commentaries* and found Buffon's *Histoire naturelle* light reading. Her enthusiasm for Russian history led her to begin to write a history of Russia from the earliest times, and she completed a play, having for its hero the legendary Oleg, which she said was an imitation of Shakespeare. Her comedies, proverbs, and tales are very numerous. To find time for all her activities she rose at five, made her own fire, and would sometimes work 15 hours a day. She seemed to have worked in bouts, taking long spells of work with intervals of relaxation. The new culture which she sought to impose on her court was not entirely superficial. She herself was kind and reasonable to her servants. She was not revengeful, and when she usurped the throne showed no hostility to her husband's advisers; nevertheless she had a fund of hardness, and showed little kindness to her son Paul.

Since Catherine was a disciple of the Encyclopaedists it was natural that she should start out with the definite intention of carrying out domestic reform in Russia, though by methods of the benevolent despotism fashionable in Europe in the period before the French Revolution shook the fabric of society. In fact she, a foreigner and usurper, had to depend for support on the nobility, whose privileges she vastly increased by relieving them of the duty of military service and giving them new powers over their serfs. She also increased their numbers by grants of Crown lands. Serfdom was not mitigated, but vastly increased under her rule. The terrible condition of the peasants led to one revolt after another in favour of one of the numerous pretenders, which culminated in the widespread rising on the Volga, the jacquerie led by Pugachev (1773–75). French culture among the landowners did not lead to any improvement in the handling of the peasants. This state of affairs was in startling contrast with the humanitarian tone of the *Instructions* which Catherine drew up for the grand commission which she summoned in Dec. 1766 to Moscow to advise on internal reform. The *Instructions*, based principally on the works of Montesquieu and Beccaria, were so radical that their circulation in France was forbidden. Very little came of the 18 months' work of the grand commission, except in the development of the organization of local government. With the outbreak of the French Revolution Catherine, like other European sovereigns, fell back on methods of repression. Radishchev, who wrote in his *Journey from St. Petersburg to Moscow* (1790) a truthful account of the condition of the peasants, was banished to Siberia, though the sentiments expressed were only those of Catherine's own *Instructions* of 1766. Catherine had some able assistants in her domestic administration, notably Sivers.

The foreign policy of her reign aimed at the expansion of Russia, and from that point of view was brilliantly successful. Catherine knew the limits to which she could safely go in the "russification" of frontier districts, and showed a certain liberality to the populations which she incorporated. She conducted her own foreign policy, and the galaxy of excellent soldiers and diplomats which she gathered round her carried out her instructions implicitly. She had the gift of discovering ability, and kept in the closest touch with all her servants. Among her generals were Alexander Galitsin, Rumyantsev, Peter Panin, Suvorov, and Potemkin. Suvorov was one of the greatest of Russian generals, but he never enjoyed quite the confidence she gave to Potemkin, whose military abilities were mediocre, but who was first her lover and then her close friend and correspondent. Her chief advisers and assistants in foreign business were Nikita Panin, Bezborodko, Repnin, Dmitri Galitsin and Vorontsoff. The story of the two shameless partitions of Poland and of the wars with Turkey which gave Russia the Crimea and free access to the Black sea for the products of the Ukraine is told under RUSSIA: *History*. It is sufficient to say here that the extension of Russian territory during her reign to the Niemen and the Dniester on the west, and to the Black sea on the south must be placed primarily to the account of Catherine's diplomacy and direction, well served as she was by her generals and her ministers.

She died on Nov. 10, 1796, of apoplexy.

The original sources for the history of her policy and her character are to be found in the publications of the Imperial Russian Historical Society, vols. i.–cix. (St. Petersburg), begun in 1867; her private and official correspondence will be found in vols. i., ii., iv., v., vi., vii., viii., ix., x., xiii., xiv., xv., xvii., xx., xxiii., xxxii., xxxiii., xxxvi., xlii., xliii., xlvii. xlviii., li., lvii., lxvii., lxviii., lxxxvii., xcvii., xcviii., cvii., cxv., cxviii. The *Memoires de l'imperatrice Catherine II., écrits par elle-même* (London 1859), with pref. by Alex. Herzen, bring her life up to the end of 1759, but were not begun until 1780. They must be used with caution, especially as regards her husband Peter III. *See* also A. Brückner, "Katharina die Zweite," in *Allgemeine Geschichte in Einzeldarstellungen* (Berlin 1883); O. Hoetzsch, "Catherine II.," in *Camb. Mod. Hist.* vol. vi., where a bibliography will be found. A complete bibliography was prepared by B. von Bilbassoff, *Katharina II., Kaiserin von Russland in Urteile der Weltliteratur* (Berlin, 1897). *See* also Princesse Lucien Murat, *La vie amoureuse de la grande Catherine* (1927); *Mémoires*, trs. by Katherine Anthony (1927); *Correspondence with Sir Charles Hanbury-Williams*, ed. and trans. by the Earl of Ilchester and Mrs. Langford-Brooke (1928).

CATHERINE DE MEDICI (1519–1589), queen of France, was born in Florence in 1519. She was a daughter of Lorenzo II. de Medici and a French princess, Madeleine de la Tour d'Auvergne. Having lost both her parents at an early age, Catherine was sent to a convent to be educated; and she was only 14 when she was married (1533) at Marseilles to the duke of Orleans, afterwards Henry II. It was her uncle, Pope Clement VII., who arranged the marriage with King Francis I., Henry's father, who was glad to strengthen his influence in the Italian peninsula. For ten years after her marriage she had no children. In consequence, a divorce began to be talked of at court. But Catherine had the happiness of bringing her husband grandchildren ere he died. During his reign (1547–59), Catherine lived a quiet and passive but observant life. Henry being completely under the influence of his mistress, Diane de Poitiers, she had little authority. In 1552, when the king left the kingdom for the campaign of Metz, she was nominated regent, but with very limited powers. This continued even after the accession of her son Francis II. Francis was under the spell of Mary Stuart, and she, little disposed to meddle with politics on her own account, was managed by her uncles, the cardinal of Lorraine and the duke of Guise. The queen-mother, however, soon grew weary of the domination of the Guises, and entered upon a course of secret opposition. On April 1, 1560, she placed in the chancellorship Michel de l'Hôpital (*q.v.*), who advocated the policy of conciliation.

On the death of Francis (Dec. 5, 1560), Catherine became regent during the minority of her second son, Charles IX. She was then 41 years old, but, although she was the mother of nine children, she was still very vigorous and active. She retained her in-

fluence for more than 20 years in the troubled period of the wars of religion. At first she listened to the moderate counsels of l'Hôpital in so far as to avoid siding definitely with either party. Like so many of the Italians of that time she looked upon statesmanship as a career in which finesse, lying and assassination were the most effective weapons. By habit a Catholic but above all things fond of power, she was determined to prevent the Protestants from getting the upper hand yet resolved not to allow them to be utterly crushed, in order to use them as a counterpoise to the Guises. This trimming policy met with little success; rage and suspicion so possessed men's minds that she could no longer control the opposing parties, and one civil war followed another to the end of her life.

In 1567, after the "Enterprise of Meaux," she dismissed l'Hôpital and joined the Catholic party. But, having failed to crush the Protestant rebellion by arms, she resumed in 1570 the policy of peace and negotiation. She conceived the project of marrying her favourite son, the duke of Anjou, to Queen Elizabeth of England, and her daughter Margaret to Henry of Navarre. To this end she became reconciled with the Protestants and allowed Comte Coligny to return to court and to re-enter the council. Of this step she quickly repented. Charles IX conceived a great affection for the admiral and showed signs of taking up an independent attitude. Catherine, thinking her influence menaced, sought to regain it, first by the murder of Coligny and, when that had failed, by the massacre of St. Bartholomew (*q.v.*). The chief responsibility for this crime, therefore, rests with Catherine; unlike the populace, she had not even the excuse of fanaticism. After the death of Charles in 1574, and the succession of Anjou under the name of Henry III, Catherine pursued her old policy of compromise and concessions; but as her influence is lost in that of her son, it is unnecessary to dwell upon it. She died on Jan. 5, 1589, a short time before the assassination of Henry, and the consequent extinction of the house of Valois.

In her taste for art and her love of magnificence and luxury, Catherine was a true Medici; in architecture especially she was well versed, and Philibert de l'Orme relates that she discussed with him the plan and decoration of her palace of the Tuileries. Catherine's policy provoked a crowd of pamphlets, the most celebrated being the *Discours merveilleux de la vie, actions et déportemens de la reine Catherine de Medicis*, in which Henri Estienne undoubtedly collaborated.

CATHERINE OF ARAGON (1485–1536), queen of Henry VIII of England, daughter of Ferdinand and Isabella of Spain, was born on Dec. 15, 1485. She left Spain in 1501 to marry Arthur, prince of Wales, eldest son of King Henry VII, and landed at Plymouth on Oct. 2. The wedding took place on Nov. 14 in London, and soon afterward Catherine accompanied her husband to Wales, where, in his 16th year, the prince died on April 2, 1502. On June 25, 1503, she was formally betrothed to the king's second son, Henry, now prince of Wales, and a papal dispensation for the alliance was obtained. The marriage, however, did not take place during the lifetime of Henry VII. Ferdinand endeavoured to cheat the English king of the marriage portion agreed upon, and Henry made use of the presence of the unmarried princess in England to extort new conditions and especially to urge the marriage of his daughter Mary to the archduke Charles, grandson of Ferdinand, and afterward Charles V. Catherine was thus from the first the unhappy victim of state politics. Writing to Ferdinand on March 9, 1509, she describes the state of poverty to which she was reduced and declares the king's unkindness impossible to be borne any longer.

Henry VIII married her on June 11, 1509. At first he showed himself an affectionate husband, and the alliance with Ferdinand was maintained against France. During Henry's invasion of France in 1513 she was made regent; she made the preparations for the Scottish expedition and was riding north to put herself at the head of the troops when the victory of Flodden Field ended the campaign. After Henry's return next year there was a breach with Ferdinand, and the king angrily reproached his wife; but she took occasion in 1520, during the visit of her nephew Charles V to England, to urge the policy of gaining his alliance rather than that of France. Immediately on his departure, on May 31, 1520, she accompanied the king to France, on the visit to Francis I, when the sovereigns met at the Field of the Cloth of Gold; but in 1522 war was declared against France and the emperor again welcomed to England. She is represented by Shakespeare as pleading in 1521 for the unfortunate duke of Buckingham. Between Jan. 1510 and Nov. 1518 Catherine gave birth to six children (including two princes), who were all stillborn or died in infancy except Mary, born in 1516, and opinion ascribed this series of disasters to the curse on incestuous unions. To avoid a fresh dispute concerning the succession and the revival of the civil war, a male heir to the throne was a pressing necessity. The question of the possible dissolution of the marriage occupied Henry's mind. It was doubtful whether the pope had the power to legalize his marriage with Catherine, his brother's betrothed, and the case for the desired divorce was therefore more hopeful.

Rumours, probably then unfounded, of an intended divorce had been heard abroad as early as 1524. But the creation in 1525 of the king's illegitimate son Henry, as duke of Richmond—the title borne by his grandfather Henry VII—and the precedence granted to him over all the peers as well as the princess Mary, together with the special honour paid at this time by the king to his own half-sister Mary, were the first real indications of the king's thoughts. In 1526 and perhaps earlier Thomas Wolsey had been making tentative inquiries at Rome on the subject. In May 1527 a collusive and secret suit was begun before the cardinal, who, as legate, summoned the king to defend himself from the charge of cohabitation with his brother's wife; but these proceedings were dropped. On June 22 Henry informed Catherine that they had been living in mortal sin and must separate. During Wolsey's absence in July at Paris, where he had been commissioned to discuss vaguely the divorce and Henry's marriage with Renée, daughter of Louis XII, Anne Boleyn (*q.v.*) is first heard of in connection with the king, his affection for her having, however, begun probably as early as 1523, and the cardinal on his return found her openly installed at the court. In October 1528 the pope issued a commission to Cardinal Campeggio and Wolsey to try the cause in England and bound himself not to revoke the case to Rome, confirming his promise by a secret decretal commission which, however, was destroyed by Campeggio. But the trial was a sham. Campeggio was forbidden to pronounce sentence without further reference to Rome, and was instructed to create delays, the pope assuring Charles V at the same time that the case should be ultimately revoked to Rome.

The object of all parties was now to persuade Catherine to enter a nunnery and thus relieve them of further embarrassment. While Henry's envoys were encouraged at Rome in believing that he might then make another marriage, Henry himself gave Catherine assurances that no other union would be contemplated in her lifetime. But Catherine with courage and dignity held fast to her rights, demanded a proper trial and appealed not only to the bull of dispensation, the validity of which was said to be vitiated by certain irregularities, but to a brief granted for the alliance by Pope Julius II. Henry declared the latter to be a forgery and endeavoured unsuccessfully to procure a declaration of its falsity from the pope. The court of the legates accordingly opened on May 31, 1529, the queen appearing before it on June 18 for the purpose of denying its jurisdiction. On the 21st both Henry and Catherine presented themselves before the tribunal, when the queen threw herself at Henry's feet and appealed for the last time to his sense of honour, recalling her own virtue and helplessness. Henry replied with kindness, showing that her wish for the revocation of the cause to Rome was unreasonable in view of the paramount influence then exercised by Charles V on the pope. Catherine nevertheless persisted in making appeal to Rome, and then withdrew. After her departure Henry, according to Cavendish, Wolsey's biographer, praised her virtues to the court. "She is, my lords, as true, as obedient, as conformable a wife as I could in my phantasy wish or desire. She hath all the virtues and qualities that ought to be in a woman of her dignity or in any other of baser estate." On her refusal to return, her plea was overruled and she was adjudged contumacious, while the sittings of the court continued in her absence. Subsequently the legates paid her a private visit of advice, but were unable to move her from her resolution. Finally, however, in July 1529, the case was, according to her wish, and as the result of the treaty of Barcelona and the pope's complete surrender to Charles V, revoked by the pope to Rome: a momentous act, which decided Henry's future attitude and occasioned the downfall of the whole papal authority in England. On March 7, 1530, Pope Clement issued a brief forbidding Henry to make a second marriage and ordering the restitution of Catherine to her rights till the cause was determined; while at the same time he professed to the French ambassador, the bishop of Tarbes, his pleasure should the marriage with Anne Boleyn have been already made, if only it were not by his authority (Cal. of State Papers, For. and Dom. iv, 6290). The same year Henry obtained opinions favourable to the divorce from the English, French and most of the Italian universities, but unfavourable answers from Germany, while a large number of English peers and ecclesiastics, including Wolsey and Archbishop Warham, joined in a memorial to the pope in support of Henry's cause.

Meanwhile, Catherine was still treated by Henry as his queen. On

May 31, 1531, she was visited by 30 privy councillors, who urged the trial of the case in England, but they met only with a firm refusal. On July 14 Henry left his wife at Windsor, removing himself to Woodstock, and never saw her again. In August she was ordered to reside at the Moor in Hertfordshire, and at the same time separated from the princess Mary, who was taken to Richmond. In October she again received a deputation of privy councillors and again refused to withdraw the case from Rome. In 1532 she sent the king a gold cup as a new year's gift, which the latter returned, and she was forbidden to hold any communication with him. Her cause found champions and sympathizers among the people, among the court preachers and in the house of commons, while Bishop Fisher had openly taken her part in the legatine trial. Subsequently Catherine was moved to Bishops Hatfield, while Henry and Anne Boleyn visited Francis I. Their marriage, anticipating any sentence of the nullity of the union with Catherine, took place after their return about Jan. 25, 1533. On May 10 Archbishop Cranmer opened his court and declared on the 23rd the nullity of Catherine's marriage and the validity of Anne's. On Aug. 10 the king caused proclamation to be made forbidding her the style of queen; but Catherine refused to yield the title for that of princess dowager. Not long afterward she was moved to Buckden in Huntingdonshire. There her household was considerably reduced, and she found herself hemmed in by spies and in fact a prisoner. A project for removing Catherine from Buckden to Somersham, in the isle of Ely, with a still narrower maintenance, was prevented by her resistance. The attempt in November to incriminate the queen in connection with Elizabeth Barton failed.

She passed her life now in religious devotions. On March 23, 1534, the pope pronounced her marriage valid, but by this time England had thrown off the papal jurisdiction, the parliament had transferred Catherine's jointure to Anne Boleyn, and the decree had no effect on Catherine's fortunes. She refused to swear to the new act of succession, which declared her marriage null and Anne's infant the heir to the throne, and soon afterward she was moved to Kimbolton, where she was well treated. On May 21 she was visited by the archbishop of York and Tunstall, bishop of Durham, who vainly threatened her with death if she persisted in her refusal. She was kept in strict seclusion, separated from Mary and from all outside communications, and in Dec. 1535 her health gave way. She died on Jan. 8, 1536, not without suspicions of poison, which, however, may be dismissed. She was buried by the king's order in Peterborough cathedral. Before her death she dictated a last letter to Henry, according to Polydore Vergil, expressing her forgiveness, begging his good offices for Mary and concluding with the astounding assurance—"I vow that mine eyes desire you above all things." The king himself affected no sorrow at her death and thanked God there was now no fear of war.

Catherine is described as "rather ugly than otherwise; of low stature and rather stout; very good and very religious; speaks Spanish, French, Flemish, English; more beloved by the islanders than any queen that has ever reigned." She was a woman of considerable education and culture, her scholarship and knowledge of the Bible being noted by Erasmus, who dedicated to her his book on *Christian Matrimony* in 1526. She endured her bitter and undeserved misfortunes with extraordinary courage and resolution, and at the same time with great womanly forbearance, of which a striking instance was the compassion shown by her for the fallen Wolsey.

Hume, *The Wives of Henry VIII* (1905).

CATHERINE OF BRAGANZA (1638–1705), queen consort of Charles II of England, daughter of John IV of Portugal by Louisa de Gusman, daughter of the duke of Medina Sidonia, was born at Vila Viçosa, Port., on Nov. 25, 1638. She was a useful medium for contracting an alliance with England, and negotiations for a marriage, begun during the reign of Charles I, were renewed immediately after the Restoration. On June 23, 1661, in spite of Spanish and Dutch opposition, the marriage contract was signed, by which England secured Tangier and Bombay, valuable trading privileges, religious and commercial freedom in Portugal, and 2,000,000 Portuguese crowns (about £300,000), in return for military and naval support to be given to Portugal against Spain, and liberty of worship for Catherine; in May 1662 she reached England, and the marriage took place in London. Catherine had little personal charm, and Charles's preoccupation with his mistresses soon provoked a scene at court, where Catherine at first refused to receive the reigning favourite, Lady Castlemaine. Eventually, however, Catherine came to accept the position and showed considerable kindness to the king's mistresses and bastards. Charles, in return, generally treated her fairly kindly, but she always played a very [illegible]condary role at court. As the prospect of her bearing children diminished, schemes were set on foot to procure a divorce on various pretexts. As a Roman Catholic Catherine was attacked by the inventors of the Popish Plot; in 1678 the murder of Sir Edmund Berry Godfrey was attributed to her servants, and Titus Oates accused her of a design against the king. On Nov. 24 Oates brought a charge of high treason [illegible] commons passed an address for her removal from Whitehall, but it was only the king's protection that saved her from having to stand trial in June 1679. On Nov. 17 in the house of lords, the earl of Shaftesbury moved for a divorce, so that Charles might marry a Protestant, but the bill was opposed by the king and found little support among the peers. After the Oxford parliament Charles's influence revived and the queen's position was no more assailed.

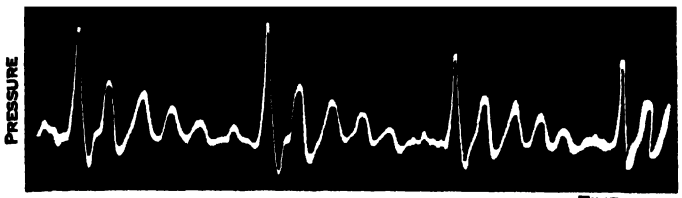
During Charles's last illness in 1685 Catherine did much to assist his reconciliation with the Roman Catholic Church, and she exhibited great grief at his death. She afterward resided at Somerset house and at Hammersmith, where she had privately founded a convent. She interceded with great generosity, but ineffectually, for the duke of Monmouth the same year. On June 10, 1688, she was present at the birth of the prince of Wales and later gave evidence before the council that he was in fact Mary of Modena's child. She maintained at first good terms with William and Mary; but the practice of her religion aroused jealousies, while her establishment at Somerset house was said to be the home of cabals against the government; and in 1691 she settled for a short time at Euston. She left England finally in March 1692 and took up her residence at the palace of Bemposta, built by herself, near Lisbon, Port. In 1703 she supported the Methuen treaty, which cemented still further the alliance between Portugal and England, and in 1704 she was appointed regent of Portugal during the illness of her brother, King Pedro II, her administration being distinguished by several successes gained over the Spaniards. She died on Dec. 31, 1705, leaving her great wealth, the result of long hoarding, apart from charitable legacies, to King Pedro.

See L. C. Davidson, *Catherine of Braganza* (London, 1908); J. Mackay, *Catherine of Braganza* (London, Toronto, 1937).

CATHERINE OF VALOIS (1401–1437), queen of Henry V of England, daughter of Charles VI of France by Isabel of Bavaria, was born in Paris on Oct. 27, 1401. After negotiations for a marriage between Henry, prince of Wales, afterward Henry V, and each of her two elder sisters had broken down, Henry IV proposed that his son should marry Catherine in 1413, and Henry V renewed this proposal when he became king in March of the same year, demanding, however, a large dowry and the restoration of Normandy and other French territories. War broke out on the rejection of these demands, but finally, after the treaty of Troyes, Henry and Catherine were betrothed on May 21, 1420, and married at Troyes on June 2. Catherine was crowned in Westminster abbey in Feb. 1421, and gave birth to a son, afterward Henry VI, in the following December. In May 1422 she joined Henry in France, and after his death in the following August she returned to England. Her name now began to be coupled with that of Owen Tudor, a Welsh squire, and when in 1428 Humphrey, duke of Gloucester, secured the passing of an act to prevent her from marrying without the consent of the king and council, she seems already to have been married to Tudor. In 1436 Tudor was imprisoned, and Catherine retired to Bermondsey abbey, where she died on Jan. 3, 1437. By Tudor Catherine had three sons and a daughter; the eldest son, Edmund, created earl of Richmond in 1452, was the father of Henry VII.

See Agnes Strickland, *Lives of the Queens of England*, vol. iii, new ed. (London, 1851); J. H. Wylie and W. T. Waugh, *The Reign of Henry the Fifth*, 3 vol. (Cambridge, 1914–29).

CATHETUS, in architecture, the central circular form round which the volute or spiral of the Ionic or Composite order twists.



CATHODE, the conductor by which an electric current leaves an electrolyte (*q.v.*) or a discharge tube. It is also called the "negative" electrode. (*See* also ANODE; ELECTRICITY, CONDUCTION OF: *Conduction in Liquids* and *Conduction in Gases.*)

CATHODE-RAY OSCILLOGRAPH. This instrument makes use of a sharply focused electron beam to display scientific data on a luminescent screen similar to that used in television. It is in a sense a modernization of the combination of a sensitive flame and rotating mirror described in 19th-century physics books.

As described in the article RADAR, the vacuum tube ordinarily used focuses the electrons emitted from a hot cathode into a narrow beam which serves as a pointer. The beam passes between two pairs of metal plates and is deflected in a horizontal direction by an amount proportional to the electrical voltage across one pair of plates while it is deflected vertically by the second pair. If desired the intensity of the beam can be controlled by means of a third voltage placed on a metal mesh or grid near the cathode. After passing between the deflecting plates, the beam is allowed to impinge on a fluorescent screen which glows brightly at the point where the electrons hit it. The combination makes it possible to obtain a luminous graph relating the two applied

voltages. Thus, if the deflecting voltages are simple harmonic waves whose periods are integrally related, the spot will trace out a pattern similar to the classical ones formed optically by the tuning forks of Jules Antoine Lissajous.

A typical application of the oscillograph is illustrated by the accompanying figure. In order to form this pattern the voltage across the horizontal deflecting plates was changed at a uniform rate for about one-thirtieth of a second, causing the spot to move from the left side of the screen to the right with constant velocity.

BY COURTESY OF DAVID ROGIN CO

TIME VARIATION OF SOUND PRESSURE IN A SHORT *a*, AS IN "BRITANNICA" (FIRST *a*)

At the same time the letter *a* as in "Britannica" was spoken into a microphone. The varying sound pressure at the microphone gave rise to a proportional voltage, and this after amplification was applied to the vertical plates resulting in a graph of the time variation of sound pressure.

Almost any graph can be plotted on the oscillograph by generating horizontal and vertical voltages proportional to the lengths, velocities or other quantities to be studied. The main power of the device comes from the extreme speed with which events can be recorded: trace speeds of 200 in. in one-millionth of a second have been utilized.

Many variations of the oscillograph tube have been made since the early one of Ferdinand Braun in 1897. Some for ultrafast measurements use patterns of microscopic dimensions; others for lecture purposes project the graphs on a movie screen. It has become perhaps the instrument most generally used by radio laboratories and also by radio repairmen. It finds increasing use in almost all branches of engineering and science.

McIlwain, 4th ed., 2:15-41 (New York, 1950; London, 1951). (L. B. A.)

CATHODE RAYS are the streams of negatively charged particles leaving the cathode in a discharge tube containing a gas at a low pressure (*see* ELECTRICITY, CONDUCTION OF: *Conduction in Gases*). The cathode rays consist of electrons (*see* ELECTRON, THE). Cathode rays have many applications, one of the chief being the excitation of X-rays by the impinging of swift electrons against a hard anticathode (*see* also COOLIDGE TUBE; X-RAYS, NATURE OF; SPECTROSCOPY, X-RAY). This bombardment, besides exciting X-rays, generates a considerable amount of heat and the anti-cathode can be used as a *cathode ray furnace* for melting small quantities of metal, etc. Forms of apparatus making use of the deflection of a beam of cathode rays by magnetic and electric fields are the *cathode ray oscillograph*, or cathode ray tube, which indicates the variation and values of an alternating current or voltage (*see* INSTRUMENTS, ELECTRICAL MEASURING), and the *cathode ray manometer*, in which a change of pressure is communicated to tourmaline crystals which become electrically charged (*see* ELECTRICITY) and produce an electric field which is measured by a cathode ray oscillograph.

CATHOLIC, derived from a Greek word meaning "universal" and used by ecclesiastical writers since the 2nd century to distinguish the church at large from local communities or heretical and schismatic sects. A notable exposition of the meaning of the term, as it had developed during the first three centuries, was given by Cyril of Jerusalem (348): the church is called catholic on the fourfold ground of its world-wide extension, its doctrinal completeness, its adaptation to the needs of men of every kind, and its moral and spiritual perfection (*Catech.*, xviii, 23). The theory that what has been universally taught or practised is true was first fully developed by St. Augustine in his controversy with the Donatists (393–420), but it received classic expression in a paragraph of St. Vincent of Lerin's *Commonitorium*, ii, 6 (434), from which the well-known formula, *quod ubique, quod semper, quod ab omnibus creditum est,* is derived. St. Vincent maintained—curiously enough apropos of an extreme Augustinian theory of grace—that the true faith was that which the church professed throughout the world in agreement with antiquity and the consensus of distinguished theological opinion in former generations (*cf. op. cit.*, ii, 3, 6, xx). Thus the term tended to acquire the sense of orthodox.

Some confusion in the history of the term has been inevitable as various groups, which have been condemned by Rome as heretical or schismatic, have not renounced their claim to the note of catholicity, so that in the modern world not only the Roman Catholic Church but also the Eastern Orthodox Church, the Anglican Church, and a variety of national churches and minor sects claim to be Catholic, if not the only true Catholic Church. From this point of view the meaning attached to the term "Catholic" and the claim to catholicity will be conditioned by the theory of the nature and constitution of the church accepted, being rigid and exclusive or tolerant and comprehensive as that is rigid or tolerant. The earlier theologians of the Anglican Church were primarily interested in proving the agreement of the Anglican theology with the teaching of the ante-Nicene Fathers, but with the Oxford movement a school of theologians arose who interpreted the catholicism of the Church of England in a much wider sense. A product of this school was the so-called "Branch theory" of the church, which maintained that the Anglican, Roman and Eastern Orthodox Churches were all branches of the one true Catholic Church, and that reunion could be achieved by concessions of these three divisions on controversial questions which divided them without affecting their catholic character. But this theory has been repeatedly condemned by Roman theologians. It has also failed to recommend itself to the Eastern Orthodox Church. (*See* also ORTHODOX EASTERN CHURCH.)

CATHOLIC APOSTOLIC CHURCH, THE, a religious community often called "Irvingites," though neither actually founded nor anticipated by Edward Irving (*q.v.*). Irving's relation to this community was, according to its members, somewhat similar to that of John the Baptist to the early Christian Church, *i.e.* he was the forerunner and prophet of the coming dispensation, not the founder of a new sect; and indeed the only connection which Irving seems to have had with the existing organization of the Catholic Apostolic body was in "fostering spiritual persons who had been driven out of other congregations for the exercise of their spiritual gifts." Shortly after Irving's trial and deposition (1832), certain persons were, at some meetings held for prayer, designated as "called to be apostles of the Lord" by certain others claiming prophetic gifts. In the year 1835, six months after Irving's death, six others were similarly designated as "called" to complete the number of the "twelve," who were then formally "separated," by the pastors of the local congregations to which they belonged, to their higher office in the universal church on the 14th of July 1835. This separation is understood by the community not as "in any sense being a schism or separation from the one Catholic Church, but a separation to a special work of blessing and intercession on behalf of it." The "apostles" always held the supreme authority, though, as their number dwindled, "coadjutors" were appointed to assist the survivors, and to exercise the functions of the "apostolate." The last "apostle" died on the 3rd of February 1901.

For the service of the church a comprehensive book of liturgies and offices was provided by the "apostles." It dates from 1842 and is based on the Anglican, Roman and Greek liturgies. Lights, incense, vestments, holy water, chrism, and other adjuncts of worship are in constant use. The ceremonial in its completeness may be seen in the church in Gordon Square, London, and elsewhere. The community has always laid great stress on symbolism, and in the eucharist, while rejecting both transubstantiation and consubstantiation, holds strongly to a real (mystical) presence. It

stresses also the "phenomena" of Christian experience and deems miracle and mystery to be of the essence of a spirit-filled church.

Each congregation is presided over by its "angel" or bishop (who ranks as angel-pastor in the Universal Church); under him are four-and-twenty priests, and with these are the deacons, seven of whom regulate the temporal affairs of the church—besides whom there are also "sub-deacons, acolytes, singers and door-keepers." The priesthood is supported by tithes.

Bosworth, *Restoration of Apostles and Prophets, Readings on the Liturgy, The Church and Tabernacle* and *The Purpose of God in Creation and Redemption* (6th ed., 1888); G. Miller, *History and Doctrines of Irvingism* (1878).

CATHOLIC EMANCIPATION, the movement for the abolition of the penal laws against Catholics. (*See* ENGLISH HISTORY; IRELAND; ROMAN CATHOLIC CHURCH.)

CATHOLIC UNIVERSITY OF AMERICA, THE, an institution of higher education at Washington, D.C., founded at the third plenary council of Baltimore in 1884. The constitutions of the university were approved by Pope Leo XIII, and the graduate school of sacred sciences was opened Nov. 13, 1889. A school of philosophy and social sciences was inaugurated in 1895, followed by the school of law (1895) and the school of canon law (1923). A reorganization of the schools took place in 1930, when all courses in philosophy, letters and sciences, except technological, were grouped under the graduate school of arts and sciences and the college of arts and sciences. The technological courses were grouped under a school of engineering and architecture. Schools of social work, nursing education and social science were later added. In 1942 the university's teaching staff numbered 231. The enrolment was 2,027, of whom 1,029 were religious students and 998 lay students.

CATILINE (LUCIUS SERGIUS CATILINA) (*c.* 108–62 B.C.), a member of an ancient but impoverished patrician family of Rome. He was a supporter of Sulla, and during the proscription he was conspicuous for his greed and cruelty. He was guilty of at least one murder. In 77 he was a quaestor, in 68 praetor and in 67-66 governor of Africa. His impeachment for extortion having disqualified him as a candidate for the consulship, he formed a conspiracy, behind which, in all probability, were Crassus and Caesar. The new consuls were to be murdered on Jan. 1, but the plot—the execution of which was deferred till Feb. 5—failed. Soon after, Catiline was acquitted through bribery in the trial for extortion. His scheme widened. The city was to be fired; those who opposed the revolution were to be slain; all debts were to be cancelled; there was to be a proscription of wealthy citizens. Catiline intended to secure the consulship for 63 with C. Antonius as colleague, but Cicero got first place, and Catiline was defeated. C. Antonius, in whom Catiline hoped to find a supporter, was won over by his colleague Cicero. Before the next *comitia consularia* assembled, the orator had given so impressive a warning of impending danger that Catiline was once more rejected (63), and the consuls were invested with absolute authority. Catiline now resolved upon open war; preparations were set on foot throughout Italy, especially in Etruria, where revolt was raised by C. Manlius (or Mallius), one of Sulla's veterans. A plan to murder Cicero in his own house on the morning of Nov. 7 was frustrated. On the next day Cicero attacked Catiline so vigorously in the senate (in his first Catilinarian oration) that he fled to his army in Etruria. Next day Cicero awoke the terror of the people by a second oration delivered in the forum, in consequence of which Catiline and Manlius were declared public enemies, and the consul Antonius was despatched with an army against them. Meanwhile the conspirators in the city tried to induce some Gallic envoys who happened to be in Rome to join them. The plot was betrayed to Cicero, at whose instigation documentary evidence was obtained, implicating Lentulus and others. They were arrested, proved guilty and on Dec. 5 put to death in the underground dungeon on the slope of the Capitol. This act was afterwards attacked as a violation of the constitution, on the ground that the senate had no power of life and death over a Roman citizen. In the beginning of 62 Catiline saw his legions shut in between those of Metellus Celer and C. Antonius. Near Pistoria he was completely defeated by Antonius, and himself fell in the battle. It must not be forgotten that our authorities for this conspiracy were all members of the aristocratic party. Some of the incidents given as facts by Dio Cassius are absurdities; and Cicero paid more regard to the effect than to the truthfulness of an accusation. We find him at one time seeking a political union with Catiline; at another, declaiming against him as a murderer and profligate. Lastly, though Sallust's vivid narrative is consistent throughout, it is obvious that he cherished very bitter feelings against the democratic party. Nevertheless, we cannot regard Catiline as an honest enemy of the oligarchy, or as a disinterested champion of the provincials.

IV., and part II. pp. 446–473 (1923); Tyrrell and Purser's ed. of Cicero's *Letters* (index vol. *s.v.* "Sergius Catilina").

CATINAT, NICHOLAS (1637–1712), marshal of France, was born on Sept. 1, 1637, in Paris, entered the Gardes Françaises at an early age, and distinguished himself at the siege of Lille in 1667. He served with great credit in the campaigns of 1676–78 in Flanders, was employed against the Vaudois in 1686, and after taking part in the siege of Philipsburg at the opening of the War of the League of Augsburg, he was appointed to command the French troops in the south-eastern theatre of war. In 1690 he conquered Savoy, and in 1691 Nice; the battle of Staffarda, won by him over the duke of Savoy in 1690, and that of Marsaglia in 1693, were among the greatest victories of the time. In 1696 Catinat forced the duke to make an alliance with France. He had in 1693 been made a marshal of France. At the beginning of the War of the Spanish Succession, Catinat was placed in charge of operations in Italy, but he was hampered by the orders of the court and the insufficiency of the forces for their task. He suffered a reverse at Carpi (1701) and was soon superseded by Villeroi, to whom he acted as second-in-command during the campaign of Chiari. He died at St. Gratien on Feb. 25, 1712.

CATION, a positively charged particle or ion which moves toward the negative electrode (cathode) during an electrolysis or an electrical discharge. The cation consists of a single atom or a group of atoms (radical) and bears a specific number of unit positive charges equal to its electrovalence. The silver ion (Ag^+) and the ammonium ion (NH_4^+) are both univalent cations while mercurous ion (Hg_2^{++}) and cupric ion (Cu^{++}) are bivalent cations. In solution the ion is usually in combination with a number of the solvent molecules. (*See* also ELECTRICITY; ELECTRICITY, CONDUCTION OF: *Conduction in Liquids;* ELECTROCHEMISTRY.)

(J. B. Ps.)

CATKIN or **AMENTUM,** a pendulous spike of simple flowers separated by bracts, found in many trees, as, for example, willow and poplar.

(*See* FLOWER.)

CATLETTSBURG, a residential city of northeastern Kentucky, U.S., on the Ohio river at the mouth of the Big Sandy, where Ohio, West Virginia and Kentucky meet; the county seat of Boyd county. It is on federal highway 60 and the Chesapeake and Ohio railway.

The population in 1950 was 4,750; it was 4,524 in 1940 by the federal census.

Oil refining and chemicals are the principal industries.

CATLIN, GEORGE (1796–1872), American ethnologist, was born at Wilkes-Barre (Pa.), in 1796. He was educated as a lawyer and practised in Philadelphia for two years; but art was his favourite pursuit, and forsaking the law he established himself at New York as a portrait painter. In 1832, realizing that the American Indians were dying out, he resolved to rescue their types and customs from oblivion. With this object he spent many years among the Indians in North and South America. He lived with them, acquired their languages, and studied very thoroughly

their habits, customs and mode of life, making copious notes and many studies for paintings. In 1840 he came to Europe with his collection of paintings, most of which are now in the National museum, Washington, as the Catlin gallery; and in the following year he published the *Manners, Customs and Condition of the North American Indians* in two volumes, illustrated with 300 engravings. This was followed in 1844 by *The North American Portfolio,* containing 25 plates of hunting scenes and amusements in the Rocky mountains and the prairies of America, and in 1848 by *Eight Years' Travels and Residence in Europe.* In 1861 he published a curious little volume, in "manugraph," entitled *The Breath of Life,* on the advantage of keeping one's mouth habitually closed, especially during sleep; and in 1868 *Last Rambles amongst the Indians of the Rocky Mountains and the Andes.* He died in Jersey city (N.J.), on Dec. 22, 1872.

See W. H. Miner, *George Catlin* with an annotated bibl. (1901); also *My Life Among the Indians* (ed. by N. G. Humphreys, 1909).

CATO, DIONYSIUS, the supposed author of the *Dionysii Catonis Disticha de Moribus ad Filium.* In the middle ages the author of the *Disticha* was supposed to be Cato the elder, who wrote a *Carmen de Moribus,* but extracts from this in Aulus Gellius show that it was in prose. Nothing is really known of the author or date of the *Disticha;* it can only be assigned to the 3rd or 4th century A.D. It is a small collection of moral apophthegms, monotheistic in character, not specially Christian. The book had a great reputation in the middle ages, and was translated into many languages; it is frequently referred to by Chaucer, and in 1483 a translation was issued from Caxton's press at Westminster.

See editions by F. Hauthal (1860), with full account of mss. and early editions, and G. Némethy (1895), with critical notes; Eng. trans. by Chase (Madison, 1922); *see* also F. Zarncke, *Der deutsche Cato* (1852), a history of middle age German translations; J. Nehab, *Der altenglische Cato* (1879); E. Bischoff, *Prolegomena zum sogenannten Dionysius Cato* (1893), in which the name is discussed; F. Plessis, *Poésie latine* (1909), 663; for mediaeval translations and editions *see* Teuffel, *Hist. of Roman Lit.* § 308, 3.

CATO, MARCUS PORCIUS (95–46 B.C.), Roman philosopher, called *Uticensis.* On the death of his parents he was brought up in the house of his uncle, M. Livius Drusus. After serving in the ranks against Spartacus (72 B.C.) he acted as military tribune (67) in Macedonia. On his return he became quaestor, and showed so much zeal and integrity in the management of the public accounts that he obtained a provincial appointment in Asia, where he strengthened his reputation. He admired the discipline which Lucullus had enforced in his own eastern command, and supported his claims to a triumph, while he opposed the pretensions of Pompey. As tribune in 62 he prosecuted L. Licinius Murena, consul-elect, for bribery. Cato supported Cicero at the time of the conspiracy of Catiline and voted for the execution of the conspirators, thus incurring the resentment of Julius Caesar, who did his utmost to save them.

Cato was now regarded as one of the leaders of the senatorial nobility. He vainly opposed Caesar's candidature for the consulship in 59, and his attempt, in conjunction with Bibulus, to prevent the passing of Caesar's agrarian law proved unsuccessful. Yet he was still an obstacle of sufficient importance for the triumvirs to desire to get rid of him. At the instigation of Caesar he was sent with a mission to settle the affairs of Cyprus (58). On his return two years later he continued to struggle against the combined powers of the triumvirs in the city, and became involved in scenes of violence and riot. He obtained the praetorship in 54, and endeavoured to suppress bribery, in which all parties were equally interested. He failed to attain the consulship, and had made up his mind to retire from public life when the civil war broke out in 49. He realized that the sole chance for the free state lay in supporting Pompey, whom he had formerly opposed. At the outset of the war he was entrusted with the defence of Sicily, but finding it impossible to hold the island he joined Pompey at Dyrrhachium. He was not present at the battle of Pharsalus, and after the battle, when Pompey abandoned his party, Cato led a small remnant of their forces into Africa. After his famous march through the Libyan deserts, he shut himself up in Utica, and even after the decisive defeat at Thapsus (46), in spite of the wishes of his followers, he determined to keep the gates closed till he had sent off his adherents by sea. When the last of the transports had left the port he cheerfully dismissed his attendants, and soon afterwards stabbed himself.

He had been reading, we are told, in his last moments Plato's dialogue on the immortality of the soul, but his own philosophy had taught him to act upon a narrow sense of immediate duty without regard to the future. He conceived that he was placed in the world to play an active part, and when disabled from carrying out his principles, to retire gravely from it. He had lived for the free state, and it now seemed his duty to perish with it. In politics he was a typical doctrinaire, blind to the fact that his national ideal was an anachronism. The only composition by him which we possess is a letter to Cicero (*Ad. Fam.* xv. 5). The school of the Stoics, which took a leading part in the history of Rome under the earlier emperors, looked to him as its saint and patron. Immediately after his death Cato's character became the subject of discussion; Cicero's panegyric *Cato* was answered by Caesar in his *Anticato.* Brutus, dissatisfied with Cicero's work, produced another on the same subject; in Lucan Cato is represented as a model of virtue and disinterestedness.

See his *Life* by Plutarch; also C. W. Oman, *Seven Roman Statesmen of the Later Republic, Cato . . .* (1902); Mommsen, *Hist. of Rome* (Eng. trans.), bk. v. ch. v.; Gaston Boissier, *Cicero and his Friends* (Eng. trans., 1897); esp. pp. 277 foll.; Warde Fowler, *Social Life at Rome* (1909).

CATO, MARCUS PORCIUS (234–149 B.C.), Roman statesman, surnamed "The Censor" or "The Elder," was born at Tusculum of an ancient plebeian family. He was bred to agriculture, but, having attracted the notice of L. Valerius Flaccus, he was brought to Rome, and became successively quaestor (204), aedile (199), praetor (198), and consul (195). During his term of office he vainly opposed the repeal of the Lex Appia, to restrict extravagance on the part of women. Meanwhile he served in Africa, and took part in the campaign of Zama (202). He held a command in Sardinia and again in Spain, which he subdued with great cruelty, thereby gaining a triumph (194). In the year 191 he acted as military tribune in the war against Antiochus III. of Syria. If he was not personally engaged in the prosecution of the Scipios (Africanus and Asiaticus) for corruption, it was his spirit that animated the attack upon them. Cato's enmity dated from the African campaign when he quarrelled with Scipio for his lavish distribution of the spoil amongst the troops, and his general luxury and extravagance.

Cato opposed the spread of the new Hellenic culture which threatened to destroy ancient Roman simplicity. His purpose was shown most clearly in the discharge of the censorship; hence his title of "Censor." He revised with unsparing severity the lists of senators and knights, ejecting the men whom he judged unworthy, either on moral grounds or from want of means. The expulsion of L. Quinctius Flamininus for cruelty was an example of his rigid justice. His regulations against luxury were very stringent, and he supported the Lex Orchia (181) and Lex Voconia (169). He repaired the aqueducts, cleansed the sewers, prevented private persons drawing off public water for their own use, ordered the demolition of houses which encroached on the public way, and built the first basilica in the forum near the curia. He raised the amount paid by the publican for the right of farming the taxes, and at the same time diminished the contract prices for the construction of public works.

From the date of his censorship (184) to his death in 149, Cato held no public office, but continued to distinguish himself in the senate as the persistent opponent of the new ideas. Like many others he was shocked at the licence of the Bacchanalian mysteries; and he urged the dismissal of the philosophers (Carneades, Diogenes and Critolaus), who came as ambassadors from Athens, on account of the dangerous nature of their views. Almost his last public act was to urge his countrymen to the Third Punic War and the destruction of Carthage. In 157 he was one of the deputies sent to arbitrate between Carthage and Numidia and was so struck by Carthaginian prosperity that he was convinced that the security of Rome depended on the annihilation of Carthage.

From this time, in season and out of season, he kept repeating the cry: "Delenda est Carthago" ("Carthage must be destroyed").

Cato regarded the family as the germ of the State, and proved himself a hard husband, a strict father, a severe and cruel master. There was little difference apparently, in the esteem in which he held his wife and his slaves; his pride alone induced him to take a warmer interest in his sons. The Romans respected this behaviour as a traditional example of the old Roman manners (Livy xxxix. 40).

Cato was the first Latin prose writer of any importance, and the first author of a history of Rome in Latin. His treatise on agriculture (*De Agricultura* or *De Re Rustica*) is the only work by him that has been preserved. It contains a miscellaneous collection of rules of good husbandry, conveying much curious information on the domestic habits of the Romans of his age. His most important work *Origines*, in seven books, related the history of Rome from its earliest foundations to his own day. His speeches, of which 150 were collected, were chiefly directed against the young nobles of the day. He also wrote a set of maxims for the use of his son (*Praecepta ad Filium*) and some rules for everyday life in verse (*Carmen de Moribus*). The collection of proverbs in hexameter verse, extant under the name of Cato, probably belongs to the 4th century A.D. (*See* CATO, DIONYSIUS.)

BIBLIOGRAPHY.—There are lives of Cato by Cornelius Nepos, Plutarch and Aurelius Victor, and many particulars of his career and character are to be gathered from Livy and Cicero. *See* also G. Kurth *Caton l'ancien* (Bruges, 1872); F. Marcucci *Studio critico sulle Opere di Catone il Maggiore* (1902). The best edition of the *De Agricultura* is by H. Keil (1884–91), of the fragments of the *Origines* by H. Peter (1883) in *Historicorum Romanorum Fragmenta*, of the fragments generally by H. Jordan (1860); *see* also J. Wordsworth *Fragments and Specimens of Early Latin* (1874); Mommsen *Hist. of Rome* (Eng. trans.) bk. iii. ch. xi. and xiv.; Warde Fowler *Social Life at Rome* (1909).

CATO, PUBLIUS VALERIUS, Roman poet and grammarian, was born about 100 B.C. He was the leader of the "new" school of poetry (*poetae novi*, as Cicero calls them). Its followers rejected the national epic and drama in favour of the artificial mythological epics and elegies of the Alexandrian school. The great influence of Cato is attested by the lines:—

> Cato grammaticus, Latina Siren
> Qui solus legit ac facit poetas.[1]

Our information regarding his life is derived from Suetonius (*De Grammaticis*, 11). He was a native of Cisalpine Gaul, and lost his property during the Sullan disturbances before he had attained his majority. He lived to a great age and during the latter part of his life was very poor. In addition to grammatical treatises, Cato wrote a number of poems, the best known of which were the *Lydia* and *Diana*. In the *Indignatio* (perhaps a short poem) he defended himself against the accusation that he was of servile birth. It is probable that he is the Cato mentioned as a critic of Lucilius in the lines by an unknown author prefixed to Horace, *Satires*, i. 10.

Among the minor poems attributed to Virgil is one called *Dirae* (or rather two, *Dirae* and *Lydia*). The *Dirae* consists of imprecations against the estate of which the writer has been deprived, and where he is obliged to leave his beloved Lydia; in the *Lydia*, on the other hand, the estate is envied as the possessor of his charmer. Joseph Justus Scaliger was the first to attribute the poem (divided into two by F. Jacobs) to Valerius Cato, on the ground that he had lost an estate and had written a *Lydia*. The balance of opinion is in favour of the *Dirae* being assigned to the beginning of the Augustan age, although O. Ribbeck supports the claims of Cato to the authorship. The best edition of these poems is by A. F. Näke (1847), with exhaustive commentary and excursuses; a clear account of the question will be found in M. Schanz's *Geschichte der römischen Literatur;* for the "new" school of poetry *see* Mommsen, *Hist. of Rome*, bk. v. ch. xii.; F. Plessis, *Poésie latine* (1909), 188.

CATS, JAKOB (1577–1660), Dutch poet and humorist, was born at Brouwershaven in Zeeland. He studied law at Leyden and at Orleans, and, returning to Holland, settled at The Hague, where he began to practise as an advocate. His pleading in defence of a wretched creature accused of witchcraft brought him many clients and some reputation. He had a serious love affair about this time, which was broken off on the very eve of marriage by his catching a tertian fever which defied all attempts at cure for some two years. For medical advice and change of air Cats went to England, where he consulted the highest authorities in vain. He returned to Zeeland to die, but was cured mysteriously by a strolling quack. He married in 1602 a lady of some property, Elisabeth von Valkenburg, and thenceforward lived at Gryps-kerke in Zeeland, where he devoted himself to farming and poetry. His best works are: *Emblemata* or *Minnebeelden* with *Maegden-plicht* (1618); *Spiegel van den ouden en nieuwen Tijt* (1627); *Houwelijck . . .* (1625); *Selfstrijt* (1620); *Ouderdom en Buyten-leven op. Zorgh-Vliet* (1655); and *Gedachten op. slapelooze nachten* (1661). In 1621, on the expiration of the 12 years' truce with Spain, the breaking of the dykes drove him from his farm. He was made pensionary (stipendiary magistrate) of Middelburg; and two years afterwards of Dort. In 1627 Cats came to England on a mission to Charles I., who made him a knight. In 1636 he was made grand pensionary of Holland, and in 1648 keeper of the great seal; in 1651 he resigned his offices, but in 1657 he was sent a second time to England on what proved to be an unsuccessful mission to Cromwell. In the seclusion of his villa of Sorgvliet, near The Hague, he lived from this time till his death, occupied in the composition of his autobiography (*Eighty-two Years of My Life*, first printed at Leyden in 1734) and of his poems. He is still spoken of as "Father Cats" by his countrymen.

Cats was contemporary with Hooft and Vondel and other distinguished Dutch writers in the golden age of Dutch literature, but his Orangist and Calvinistic opinions separated him from the liberal school of Amsterdam poets. He was intimate with Constantin Huygens, whose political opinions were more nearly in agreement with his own. For an estimate of his poetry *see* DUTCH LANGUAGE AND LITERATURE. Hardly known outside Holland, among his own people for nearly two centuries his work enjoyed an enormous popularity.

See G. Derudder, *Un poète néerlandais: Cats, sa vie, son oeuvre* (Calais, 1898); G. Kalff, *Jakob Cats* (1902).

CAT'S-EYE, a name given to several distinct minerals, their common characteristic being that when cut with a convex surface they display a luminous band, like that seen by reflection in the eye of a cat. (1) Precious, oriental or chrysoberyl cat's-eye. This, the rarest of all, is a chatoyant variety of chrysoberyl (*q.v.*), showing in the finest stones a very sharply defined line of light. (2) Quartz cat's-eye. This is the common form of cat's-eye, in which the effect is due to the inclusion of parallel fibres of asbestos. It is obtained chiefly from Ceylon, but, though coming from the east, it is often called "occidental cats-eye"—a term intended simply to distinguish it from the finer oriental stone. It is readily distinguished by its inferior density, its specific gravity being only 2.65, while that of oriental cat's-eye is as high as 3.7. A greenish fibrous quartz, cut as cat's eye, occurs at Hof and some other localities in Bavaria. (3) Crocidolite cat's-eye, a beautiful golden brown mineral, with silky fibres, found in Griqualand West, and much used in recent years as an ornamental stone, sometimes under the name of "South African cat's-eye." It consists of fibrous quartz, coloured with oxide of iron, and results from the alteration of crocidolite (*see* ASBESTOS). (4) Corundum cat's-eye. In some asteriated corundum the star is imperfect and may be reduced to a luminous zone, producing an indistinct cat's-eye effect. (F. W. R.)

CATSKILL, a village of New York, U.S., on the west bank of the Hudson river, 35 mi. S. of Albany; the county seat of Greene county. It is on federal highway 9W. and is served by the West Shore branch of the New York Central railroad. Population (1950) 5,336; (1940) 5,429. Catskill is a summer resort, and is the gateway to the Catskill mountain region. Near by is the spot where Rip Van Winkle had his fabled sleep of 20 years. At Leeds, on the Mohican trail just northwest of the village, is a beautiful stone arch bridge of the 18th century. The bridge was reconstructed after an old design in 1939 by the highway department of the state. The first settler there was Derrick Teunis van Vechten, in 1680. The village was incorporated in 1806.

[1] "Cato, the grammarian, the Latin siren, who alone reads aloud the works and makes the reputation of poets."

CATSKILL MOUNTAINS, a group of moderate elevation pertaining to the Allegheny plateau and not included in the Appalachian system because they lack the internal structure and general parallelism of topographic features which characterize the Appalachian ranges. They are situated mainly in Greene and Ulster counties in the state of New York, with minor sections extending into Delaware and Schoharie counties. The Catskills rise to about the general height of the Highlands of Scotland or the Harz mountains of Germany, the group containing many summits above 3,000 ft. elevation and half a dozen approaching 4,000, Slide mountain (4,204 ft.) and Hunter mountain (4,025 ft.) being the only ones exceeding that figure.

The Catskills were not subject to the general folding which marked the elevation of the main ridges of the Appalachians. This gives the mountains the features of a carved plateau with scenery of a subdued type. There are, however, a number of rugged precipices on their outer faces and a number of deeply worn gorges called "cloves." Stony clove and Kaaterskill clove are picturesque gorges, the latter containing three cascades having a total fall of about 300 ft. The Devassego falls of the Schoharie are also strikingly picturesque. Some of the views which have become noted for their magnificent panorama are Pine Orchard ledge, where there is an unobstructed view of the mountain region of Massachusetts, Vermont and New Hampshire; Kaaterskill knob, North Mountain outlook, Sunset rock, Prospect rock, and others. The mountains are, as a whole, well wooded quite up to their summits—pine, spruce, oak, hickory, beech, maple, rhododendron and mountain laurel being common. The almost total absence of lakes is remarkable.

CATT, CARRIE LANE CHAPMAN (1859–1947), U.S. leader in the woman suffrage and peace movements, was born in Ripon, Wis., Jan. 9, 1859. She graduated from Iowa State college, Ames, in 1880. She married first Leo Chapman (1884; d. 1886), then George W. Catt (1890; d. 1905). In 1890 she had her first suffrage campaign experience under Susan B. Anthony in South Dakota.

Mrs. Catt reorganized the National American Woman Suffrage association on political district lines, 1909-15, so that in working for the vote women were trained for political action; she marshalled these seasoned campaigners, 1915–20, on a national scale to influence congress to submit the 19th amendment enfranchising women, and the state legislatures to ratify it. After bitter opposition in the senate, congress submitted the amendment in 1919, and it was ratified Aug. 26, 1920. Mrs. Catt reorganized the suffrage association, then 2,000,000 strong, as the National League of Women Voters, 1919–20.

In 1902 she founded the International Woman Suffrage alliance, which held its first congress in Berlin, 1904, and was its president until she retired at the congress in Rome, 1923. In 1911–12, accompanied by Aletta Jacobs of the Netherlands, she made a pioneer feminist voyage around the world.

In 1925 she enlisted the co-operation of 11 national women's organizations in the National Committee on the Cause and Cure of War, to start a campaign of education for U.S. participation in world organization for peace. Following World War II, she was vitally interested in the success of the United Nations, using her influence to have qualified women on certain commissions. She died on March 9, 1947.

CATTANEO, CARLO (1801–1869), Italian philosopher and republican, was the founder of the review *Il Politecnico*. He was the heart and soul of the Five Days of Milan (March 18–22, 1848), and bitterly opposed the hegemony of Piedmont in Italy. On the return of the Austrians he fled to Lugano, and there he wrote his *Storia della rivoluzione del 1848* and the *Archivio triennale delle cose d'Italia* (3 vol., 1850–55). An uncompromising opponent of Cavour, he steadfastly refused to stand for election to the Italian parliament owing to his inability to take the oath of allegiance to the monarchy.

See his *Opere edite ed inedite*, ed. by A. Bertani, 7 vol. (Florence, 1881–92), *Scritti politici ed epistolari*, ed. by G. Rosa and J. W. Mario (Florence, 1892) and *Scritti storici, letterari, etc.*, ed. by C. Romussi (Milan, 1898). *See* also A. and J. Mario, *Carlo Cattaneo* (Florence, 1884); E. Zanoni, *Carlo Cattaneo nella vita e nelle opere* (1898); G. Nolli, *La Filosofia di Carlo Cattaneo* (Crema, 1901); G. Salvemini, *Le più belle pagine di Carlo Cattaneo* (Milan, 1922).

CATTANEO, DANESE DI MICHELE (1509–1573), Italian sculptor, born at Colonnata, near Carrara, pupil of Jacopo Sansovino in Rome. It is said he was taken prisoner three times by the Imperialists during the "Sacco di Roma" in 1527. He fled to Florence, where he carved the marble bust of Alessandro de Medici; and then joined Sansovino in Venice. He was employed by his master on sculptures for the Libreria di San Marco and the Zecca. Among his works in Venice are the "Apollo" crowning the fountain in the Zecca; the "St. Jerome" in San Salvatore, the figures on the tombs of Leon Loredano in SS. Giovanni e Paolo, and of Andrea Badoer in the Scuola di S. Giovanni Battista. He also worked in Padua for the church of Sant' Antonio. The fine bust of Pietro Cardinal Bembo (1547) placed on the tomb in that church is by his hand. At Verona he built the tomb of Gian Fregoso in S. Anastasia with the help of his distinguished pupil Gerolamo Campagna. He returned to Padua in 1572, but death cut short his work on the reliefs for the Capella del Santo, which were completed by Campagna. Cattaneo was also a poet; his poems *Dell'amor di Marfisa* (1562) were praised by Torquato Tasso. His grandson Niccolo collected his writings.

CATTARO (Serbo-Croatian *Kotor*), a seaport of the former kingdom of Montenegro, Yugoslavia. Pop. (1931) 5,011. The town, which is Venetian in appearance, occupies a ledge between the Montenegrin mountains and the Bocche di Cattaro, a beautiful inlet of the Adriatic, which expands into five broad gulfs united by narrower channels, and forms one of the finest natural harbours in the world.

Cattaro is strongly fortified; on the seaward side Castelnuovo (Serbo-Croatian, *Erceg-novi*) guards the main entrance to the Bocche; on the landward side, long walls run from the town to the castle of San Giovanni far above, while the barren heights of the Krivosie, toward Montenegro, are crowned by small forts.

Cattaro is a Yugoslav city, divided almost equally between the Roman Catholic and the Orthodox creeds. It is the seat of a Roman Catholic bishop with a cathedral containing some beautiful marble sculptures, a collegiate church and several convents. There is a secondary school, a naval college, an interesting naval museum, and a forest school. Cattaro is famous for its lacemaking, and also does an extensive trade in cheese. It is the chief port for Montenegro and Cetinje. Castelnuovo, a picturesque town, rose around the citadel built in 1377 by a Bosnian king.

It has at various times been occupied by Turks, Venetians, Spaniards, Russians, French, English and Austrians. The Orthodox convent of St. Sava, standing amid beautiful gardens, was founded in the 16th century and contains many fine specimens of 17th-century silversmiths' work.

Rhizon, the modern port of Risano, from which a track leads into Montenegro, was a thriving "Illyrian" city as early as 229 B.C., and gave its name to the Bocche, then known as Rhizonicus Sinus. Rhizon submitted to Rome in 168 B.C. and about the same time Ascrivium, or Ascruvium, the modern Cattaro, is first mentioned as a neighbouring city. Justinian built a fortress above Ascrivium in A.D. 535, after expelling the Goths, and a second town probably grew up on the heights around it. The city was plundered by the Saracens in 840 and by the Bulgarians in 1102. In the next year it was ceded to Serbia by the Bulgarian tsar Samuel, but revolted, and only submitted in 1184 as a protected state. It was already an episcopal see, and in the 13th century Dominican and Franciscan monasteries were established to check the spread of Bogomilism. In the 14th century it was one of the capitals of the Serbian state of Diokitiya, and Stephen Dushan (1331–55) had his mint there, while its commerce, rivalling that of Ragusa, provoked the jealousy of Venice. After the downfall of Serbia in 1389, it was seized and abandoned by Venice and Hungary in turn, and finally passed under Venetian rule in 1420. It was besieged by the Turks in 1538 and 1657, visited by plague in 1572, and nearly destroyed by earthquakes in 1563 and 1667. In

1707 it passed to Austria; in 1805 it was assigned to Italy; in 1806 the Russians occupied it and Napoleon, to whom it had been ceded, took Ragusa in its stead. From 1807–13 it was united to the French empire; in the latter year, the Montenegrins aided by the British fleet held it for 5 months, and in 1814 it was restored by the Congress of Vienna to Austria, with whom it remained until 1918. During World War I the Montenegrins arrived before Cattaro, which was a centre of submarine activity. The Slav sailors mutinied in 1918 and many of them were shot or imprisoned. In 1918 it became part of Yugoslavia, but it was occupied in 1941 by Italy.

See G. Gelcich (Gelčić), *Memorie storiche sulle Bocche di Cattaro* (Zara, 1880).

CATTEGAT or **KATTEGAT** (Scand. "cat's-throat"), a strait forming part of the connection between the Baltic and the North seas. It lies north and south between Sweden and Denmark, and connects north with the Skaggerak and south through the Sound, Great Belt and Little Belt with the Baltic sea. Length about 150 mi., extreme breadth about 88 mi., area 9,840 sq.mi., mean depth not more than about 14 fathoms. (*See* BALTIC SEA.)

CATTELL, JAMES MCKEEN (1860–1944), U.S. psychologist and editor, born at Easton, Pa., May 25, 1860, A.B. Lafayette, 1880, Ph.D. Leipzig, 1886, is known for his researches and for the organization of co-operation in science. After lectureships at Pennsylvania, Bryn Mawr and Cambridge universities, he was professor of psychology at Pennsylvania, 1888–91, the first chair in psychology. He was professor at Columbia, 1891–1917. In 1929 he was elected president of the International Congress of Psychology. With James M. Baldwin, Cattell was editor of the *Psychological Review*, 1894–1904. He reorganized *Science* in 1894 and in 1900 it became the organ of the American Association for the Advancement of Science. In 1900 he took over *Popular Science Monthly*, later the *Science Monthly*. He also edited the *American Naturalist* and *School and Society*, 1915–39. Cattell was always interested in men of science and, in part as a tool in the study of development in science, he published (1906–39) *American Men of Science*. He organized the Psychological corporation in 1921 to promote psychological aid to industry and was long its president. Cattell died Jan. 20, 1944. (W. B. Py.)

CATTERMOLE, GEORGE (1800–1868), English painter, chiefly in water colours, was born at Dickleburgh, near Diss, Norfolk, in August 1800. At the age of 16 he began working as an architectural and topographical draughtsman. Cattermole was a painter of no inconsiderable gifts, with great facility in picturesque resource. He was also a book illustrator. At the Paris exhibition of 1855 he received one of the five first-class gold medals awarded to British painters. He died on July 24, 1868. Among his leading works are "The Murder of the Bishop of Liége" (15th century), "The Armourer Relating the Story of the Sword," "The Assassination of the Regent Murray by Hamilton of Bothwellhaugh," and (in oil) "A Terrible Secret."

CATTLE. The word "cattle," which etymologically merely denotes a form of property and is practically synonymous with "chattel," is by common usage a generic term for animals of the bovine race. The several animals that may be included under the term are usually divided into the following six groups: (1) buffaloes (India, Africa, etc.); (2) bison (Europe and North America); (3) the yak (Tibet, etc.); (4) the gaur, gayal and bantin (India and further India); (5) eastern and African domesticated cattle or zebu; and (6) western or European domesticated cattle. In addition to the two last-mentioned groups the India buffalo, yak, gayal and bantin have been domesticated. Apart from the buffaloes, which constitute a relatively primitive and rather distinct type, all the species enumerated are rather closely related. The buffaloes do not hybridize with the members of the other groups, but all the rest can be interbred without difficulty and the hybrids, or at least the female hybrids, are quite fertile. (*See* also AUROCHS; BANTIN; BISON; BOVIDAE; BUFFALO; GAUR; GAYAL; OX; YAK.)

The ox was one of the earliest of all animals to be domesticated for agricultural purposes. In western Europe there is no evidence of domestication in Palaeolithic times but there are plentiful remains in the Swiss lake dwellings and other deposits of Neolithic age. Domesticated cattle existed in Egypt about 3500 B.C., and possibly much earlier, while Babylonian remains have been assigned to still more remote ages.

In all likelihood the wild ancestors of European domesticated cattle belonged to one or more of the sub-species of the auroch or urus (*Bos primigenius*) which were widely distributed in Europe, western Asia and northern Africa in prehistoric times. However, the earliest known domesticated ox in Europe was a very small, slenderly built animal, with short horns, bearing all the marks of a prolonged existence under the care of man and contrasting very markedly with the contemporary wild urus. The conclusion has been drawn that the original domestication did not occur in western Europe; probably the little ox (*Bos longifrons* or *Bos brachyceros*), together with corresponding types of sheep and pig, was brought from Asia by Neolithic man in his migrations. Later, in the Bronze age particularly, a new and larger type of cattle, showing a closer resemblance to the European wild ox, made its appearance. Probably the *Bos longifrons* had been "graded up" by crossing with the wild type. The process was, however, not universal, and even today breeds like the Shetland, Jersey, Kerry and Brown Swiss show a marked resemblance to the Neolithic type.

Whether the zebu had a separate origin from the western ox is not known; some authorities seek to relate it with the bantin or gayal. In shape, colour, habits and even in voice, it presents many points of difference from western cattle; but the most striking of these, such as the presence of a hump, or the upward inclination of the horns, are not constant. There exist in Africa, Spain, China, etc., breeds which are intermediate between zebu and European cattle, but it is likely that some, at least, of these have arisen from crossing. The economic value of cattle arose from the docility of the males for draught and the aptitude of the females for supplying milk in excess of the requirements of their offspring. Ultimately they were utilized as food but this was in a sense secondary, and among some races their flesh was regarded, for religious or other reasons, as unfit for human consumption. The breeding and rearing of cattle for the primary purpose of supplying meat is a modern development.

Terminology.—In the terminology used to describe the sex and age of cattle, the male is first a "bull-calf" and if left intact becomes a "bull"; but if castrated he becomes a "steer" and in about two or three years grows to an "ox." The female is first a "heifer-calf," growing into a "heifer" and becoming after two or three years a "cow." A heifer is sometimes operated on to prevent breeding and is then a "spayed heifer." The age at which a steer becomes an ox and a heifer a cow is not clearly defined and the practice varies. Both in the male and female emasculation is practised because the animals are assumed to fatten more readily; in the case of bulls intended for use as working oxen the object of emasculation, as in the case of stallions, is to make them quieter and more tractable in work.

BREEDS

The exact definition of a "breed" of cattle is difficult, although the term is commonly used and in practice well understood. It may be said generally to connote a particular type of animal which has for a long period been bred only with those of the same, or closely similar, type, and has hereditary characteristics which are transmissible to its offspring. In every breed, however long established, instances of atavism may and do occur, but these are eliminated and do not affect its general purity. Breeds have been established by generations of cattle breeders aiming at the attainment and preservation of a particular type and working on the principle that "like begets like." It is only within very recent times that the laws of heredity founded on the researches of Mendel have been studied as a science. There are many old-established breeds on the continent as for example the Charolais and Normande of France, the Holsteins of Holland, the Campagna di Roma of Spain, and many others, but the British breeds are of particular interest because of their influence in building up the vast herds which furnish the supplies of beef on which other countries are largely dependent. (*See* BEEF.)

Beef Breeds.—***The Shorthorn.***—The Shorthorn is an example of improvement of beef cattle by selection within a breed. In the last quarter of the 18th century two brothers, Charles and Robert Colling, farming in Durham county, England, began to improve the local cattle of the Teeswater district of that county. Their efforts were supplemented by other constructive breeders, notably Thomas Bates and Thomas Booth in Yorkshire. As many cattle of this breed have been exported to other countries from Durham, they are often called by that name.

Shorthorns are distinguishable from other breeds by their colour markings. They may be solid red, red with white markings, white or roan. Roan colour is a mixture of red and white hairs. The Shorthorn is the only modern breed that has a roan colour, making this colouring an index of Shorthorn breeding. Colour, scale and blocky conformation are characteristics of the breed.

Shorthorns are to be found in practically every country of the world. They are numerous in North America, in South America, particularly in Argentina, in Europe, being the most popular breed in the British Isles, and are bred to some extent on the continent; in Australia they have long met with favour and have also been bred quite extensively in South Africa. In the United States, Shorthorns are most numerous in the corn belt states and have been used rather extensively in other areas for grading up native or scrub cattle.

The *Shorthorn Herdbook,* the first of its kind for cattle, was begun in 1822 by George Coates. It was published as a private compilation until 1876 when it was taken over by the Shorthorn society. The first U.S. *Shorthorn Herdbook,* which registers all types of Shorthorns except the Milking type in the United States, was published in 1846 and in 1867 the first Canadian *Shorthorn Herdbook* was begun.

Strains of Shorthorns have been selected for milk and butterfat production, as well as beef, and in the United States are called Milking Shorthorns; in Canada, Dual-Purpose Shorthorns; in England and Australia, Dairy Shorthorns. In England many herds of Shorthorn cattle still show the beef and milk combination developed by the early improvers of the breed. In the United States throughout large areas in the middle west as well as in parts of the New England states, Milking Shorthorns are popular.

The Polled Shorthorn, as the name implies, is a strain within the breed possessing all of the Shorthorn characteristics except horns. This strain of polled cattle was developed in the United States in the late 1880s and early 1890s through the use of naturally hornless registered Shorthorns found within the breed. While beef characteristics have been emphasized, many good milkers have been developed among Polled Shorthorns.

Lincolnshire Red Shorthorns are a specialized type of the original Shorthorn stock.

The Hereford.—The Hereford is the product of generations of intelligent breeding work on the part of landed proprietors and tenant farmers of the fertile valleys in the county of Hereford, England. The origin of the breed has been lost in obscurity but it is thought to have descended from the primitive cattle of the country. Herefordshire is noted for its luxuriant grasses, and in this district, for many generations, the Hereford was bred for beef and draught purposes. The characteristic colour, red with white face and white markings, has been fixed for only a comparatively short time. When the first herdbook was published in 1846, the editor grouped the breed into four classes: mottle faced; light gray; dark gray; and red with white faces. Twenty-five years later all the colours but the last had practically disappeared. The outstanding characteristics of the breed are uniformity of colour, early maturity and ability to thrive under adverse conditions.

Herefords were first introduced into the United States in 1817 by Henry Clay, who imported a young bull, a cow and a heifer to his home in Kentucky. In 1860 Herefords were introduced into Canada by F. W. Stone of Guelph, Ontario. In the range areas of North America, it has become the predominating breed from Canada on the north, to Mexico on the south. In Great Britain it is chiefly bred in Herefordshire and vicinity although herds of this breed are found in Scotland, Ireland and Wales. The Hereford has met with much success also under range conditions of Australia, New Zealand, Argentina, Uruguay and southern Brazil.

The first *Hereford Herdbook*, published in 1846 as a private enterprise, was taken over by the Hereford Cattle Breeders' Association of England in 1884. The American Hereford Cattle Breeders' association was organized in 1881, and in 1934 the official name was changed to American Hereford association.

In the United States there has been developed within the Hereford breed a strain without horns. This strain was developed by Warren Gammon of Iowa by selecting naturally hornless registered Herefords that differed from the standard Hereford only in the polled character. The number of Polled Herefords has increased very rapidly and herds are to be found throughout the United States. Polled Herefords have been exported to Canada, Mexico, South America, Hawaii, the Philippines and Australia. The American Polled Hereford Breeders' association is the national organization in the United States.

The Aberdeen Angus.—This breed of black, polled beef cattle, commonly called "doddies," originated in the county of Aberdeen, in Scotland. Its ancestry is obscure. The breed was improved and the present type of the cattle fixed early in the 19th century by a number of constructive breeders among whom Hugh Watson and William McCombie were the most famous.

The characteristic features of the breed are black colour, polled head, compact and low-set body, fine quality of flesh and high dressing percentage. The Aberdeen Angus is a beef breed of the highest rank and for years purebred or crossbred Angus steers have held high places of honour at the leading fat stock shows in Great Britain and in the United States. This breed was introduced into the United States in 1873 and after that date its influence spread widely in that and other countries. The first *Polled Herdbook* of Aberdeen Angus cattle was issued in Scotland in 1862. The American Aberdeen Angus Breeders' association was organized in 1883.

The Devon.—Devons are assumed to have descended from the smaller type of aboriginal cattle of Britain. Their neat, compact, symmetrical form and deep red colour—"rubies" as they are often called—make an attractive appearance in their native home in the hills of north Devon. For centuries they were bred primarily for draught purposes but early in the 19th century Francis Quartly, a north Devon breeder, is credited with having improved the breed for beef production. His herd became the chief source of supply of stock bulls for the entire district. John Tanner Davy continued the work of improvement and numerous famous Devons descended from his herd. A grandson, Colonel Davy, founded the *Devon Herdbook* in 1851 and brought the merits of the breed to the attention of other breeders. The first authentic record of registered Devons in America was a present of seven head of registered cattle of this breed sent to Robert Patterson of Baltimore by Thomas William Coke (later Earl of Leicester) of Holkham, England. Most of the early Devons in America descended from this shipment in 1817 and later shipments to the Patterson family. Because of its adaptability and hardiness the Devon breed has found favour in many other parts of the world —in New South Wales, South Africa, southern Brazil, Uruguay and the West Indies. The greatest number of Devons in the United States are found in New England.

In south Devon where the breed is also known as South Hams, the cattle are lighter coloured, larger, less active and also less symmetrical in conformation than the cattle of hilly north Devon. The South Devon is bred primarily for dairy purposes, producing a plentiful supply of milk of high quality, from which the well-known Devonshire cream is obtained.

The Galloway.—The beginnings of this breed of polled black cattle originating in Scotland are as obscure as the Aberdeen Angus. Although its native home is the ancient province or kingdom of Galloway in southwestern Scotland, it probably had a common origin with the Aberdeen Angus. The two breeds have much in common but the Galloway is to be distinguished from the Angus by its coat of curly black hair. The breed has never attained the prominence of other beef breeds but has been used quite extensively in producing "blue-gray" crossbred cattle,

obtained by breeding white Shorthorn bulls to Galloway cows. The resulting crossbred animals produce unsurpassed and extremely popular beef carcasses. Organized effort to promote Galloway cattle first took place in 1862 in Scotland when the *Polled Herdbook* was begun. The first four volumes of this book included both Galloway and Aberdeen Angus cattle. In 1877 an independent Galloway Cattle society was formed which has been in existence ever since. The American Galloway Breeders' association was organized in 1882.

The Highland or West Highland.—The native home of this breed of cattle, sometimes called "Kyloes," is the upland region of western Scotland. Little is known of their early history though it is generally believed they are the aboriginal cattle in that district. A typical West Highland animal with wide spreading horns, long shaggy coat, sturdy frame, thick mane and heavy dewlap makes an impressive picture. The colour is variable, being yellow, red, black, brindle and a mixture of red and black with a tawny red predominating. No other breed of British ancestry equals the West Highland for hardiness and ability to thrive on scanty pasturage. Cattle of this breed are comparatively small and slow in maturing, but they make beef of fine grain and unsurpassed flavour. The breed is not distributed widely outside its native home although some exportations have been made to other countries.

The Longhorn.—The Longhorn breed of Britain is to be distinguished from longhorn cattle that were once numerous in the western range area of the United States. The latter were descended from cattle brought to America by the Spaniards and are now practically extinct. But a common characteristic of both is the excessive horn growth from which the name is derived. In England the Longhorn has been improved by selective mating. Shorthorns have largely displaced these cattle in almost every district, but a number of herds are still in existence.

The Sussex.—The Sussex breed, found in Sussex, Kent, Surrey and Hampshire, is descended from the original stock of the country and has probably undergone little change in outward appearance since the middle ages. The district in which it is bred has large areas of stiff, heavy soils, calling for great strength at the plow, a requirement for which oxen of this breed are admirably suited. The Sussex is a heavy muscular animal, dark red in colour and is valued as a good grazer where beef rather than milk is sought. It has not attained wide distribution and even in England is not widely bred outside of its own county.

The Red Poll.—The Red Poll breed represents a blending of the cattle which were common in Norfolk and Suffolk counties, England, for centuries. The horned, red, hardy Norfolk cattle were noted for their fleshing qualities while the larger-framed, hornless Suffolks were exceptionally good milkers. The merging of these two bloodlines about 1846 provided the foundation for the present breed. The aim of breeders has been to produce medium-sized, hardy, hornless cattle, red in colour, smooth and compact, and equally good as producers of beef and milk. The usefulness of the breed is now well known the world over. Exportations have been made to the United States, Canada, South Africa, Australia, New Zealand and South and Central America.

The Welsh.—The Welsh breed is black with fairly long horns. Until the beginning of the 20th century there were two types known as North and South Welsh, but they were amalgamated in 1904 when the Welsh Black Cattle society was formed and a common herdbook established. The cattle mature rather slowly but grow to a large size and furnish beef of high quality.

The Africander.—The Africander is widely distributed throughout the Union of South Africa. Although the origin of the breed is not definitely known, it probably goes back to the Indian (*Bos Indicus*) species and not to European (*Bos taurus*) cattle. The foundation of the breed was laid by the voortrekkers who valued their oxen above all other farm possessions. Before and after the Great Trek (1836) there existed a friendly rivalry among the farmers of South Africa to possess oxen that were uniform in conformation, shape of horns and colour markings, and that had hard, flinty feet and the straight easy action so desirable for trekking long distances.

The Africander has a hump over and slightly in front of the shoulders. This hump is more rounded, and blends more smoothly into the shoulder than that of zebu cattle. The colour may vary from dark to light red but dark red is preferred. After the days of the voortrekkers little attention was given to the development of milk production, but the Africander cow seldom fails to supply enough milk for her calf under the most adverse conditions. While the breed was developed primarily to produce trek oxen that would subsist entirely on the veld and survive droughts, later requirements have been for an early maturing, uniformly fleshed beef animal that maintains the hardiness of the earlier type. The Africander Cattle Breeders' society was formed in 1912 for the regulation and control of registrations of Africander cattle in the South African *Studbook*.

The first and only importation of Africander cattle into the United States was made in 1931 by the estate of Henrietta M. King (King ranch), Kingsville, Tex. The shipment consisted of 16 bulls and 13 cows and heifers.

Brahman (Zebu) Cattle.—The term Brahman has been selected by the United States department of agriculture as the name of all breeds of Indian cattle in the United States. In South America and in Europe these cattle are known as Zebus. Brahman cattle are characterized by a prominent hump above the shoulders, and an extreme development of loose, pendulous skin under the throat, on the dewlap, navel and the sheath of males. The rump is drooping. The head is long and narrow, ears are long and carried in a drooping manner, and horns differ widely according to sex and strain. The colour varies from shades of gray to black. Indian cattle, like those of Europe, vary in size, form and symmetry under the influence of local differences in climate, soil and available feed. In their native home, Indian cattle are used primarily for work and milk production. The vast majority of people of India are averse to killing them for food. Humped cattle of India were imported into the United States as early as 1849, but the importations that had the widest influence were made in 1906 and in 1924. These cattle were used in the gulf coast area of the United States for crossing with the improved breeds of beef cattle to produce a type adapted to the hot, humid conditions prevailing in that region.

The Santa Gertrudis.—This breed of cattle had its origin in the United States, having been developed by the King ranch in the state of Texas. It resulted from crossing Brahman bulls of about seven-eighths pure breeding, and purebred Shorthorn cows. Over a period of years, beginning in 1920, selective breeding was practised in which preference was given to red colour without sacrificing type and conformation. Santa Gertrudis cattle are, for the most part, solid red in colour with occasional small white markings, usually on the forehead or in the region of the flanks. They possess a slightly higher percentage of Shorthorn breeding than of Brahman.

The breed is named for one of the bulls that contributed much to its development. Santa Gertrudis cattle are the heaviest of the beef breeds when raised under similar conditions. They have great depth and length of body, with more loose skin about the neck, brisket and navel than the breeds of strictly British origin. They have proved to be highly adaptable to the gulf coast country where conditions are semitropical.

Dairy Breeds.—*The Holstein-Friesian.*—The Holstein-Friesian breed of cattle originated in north Holland and Friesland. Its chief characteristics are large size and black and white spotted markings, sharply defined rather than blended. These cattle are believed to have been selected for dairy qualities for about 2,000 years. They have long been widely distributed over the more fertile lowlands of continental Europe where they are valued highly for their milk-producing ability. However the milk has a relatively low butterfat content. When the Dutch colonized New York, they brought their cattle with them, but after the colony was ceded to the British crown and English settlers brought their own cattle, the Dutch cattle disappeared. The first exportation from Holland to the United States was in 1795, but the largest importations were made between the years 1879 and 1887. These cattle were registered in the *Holstein Herdbook* and the *Dutch*

Friesian Herdbook. In 1885 the two associations united in the Holstein-Friesian Association of America, the largest dairy breed association in the United States.

The breed is widely distributed although not so well adapted to rough, poor lands as some dairy breeds. Besides being well established in the lowland countries of western Europe in England, and throughout the United States, cattle of this breed are found in Canada, Australia, South America and South Africa.

The Jersey.—Within sight of the coast of Normandy in the English channel is a group of four small islands that have long been noted as the native home of two distinct breeds of dairy cattle—the Jersey and Guernsey. The Island of Jersey, the largest of the group, has an extremely mild climate and cattle can be outdoors most of the year. It is believed that the Jersey is descended from French cattle. Its colour is usually a shade of fawn or cream but darker shades are common. The fawn or cream has been attributed to the cattle of Normandy and the darker colour to those of Brittany. Jersey cattle are relatively small in size. The purity of the breed was recognized as early as in 1763, and in 1789 a law was passed prohibiting the importation of cattle into Jersey except for immediate slaughter. They have been introduced in large numbers into England, one of the earliest herds being formed in 1811. The first exportation to the United States was in 1850. The Jersey is adaptable to a wide range of conditions and its distribution is world-wide. Jersey milk is remarkably rich in butterfat, and for that reason animals of this breed are in demand for crossing with native stock to improve the quality of milk. The Royal Jersey Agricultural society, founded in 1833, assumed supervision of the breed on the Island of Jersey, while the English Jersey Cattle society, organized in the 1870s, became the registry association in Great Britain. The American Jersey Cattle club was organized in 1868, and under the supervision of this organization a register-of-merit system was established in 1903.

The Guernsey.—The Island of Guernsey, another of the Channel Islands, is the home of the Guernsey breed. Like the Jersey, this breed is thought to have descended from the cattle of near-by Normandy and Brittany. All of the cattle of the Channel Islands were at one time known as Alderneys. After laws had been enacted prohibiting the importation of cattle to the islands except for slaughter, the two distinct breeds—Jerseys and Guernseys—came to be recognized. Guernsey cattle are fawn coloured, marked with white, and are larger than their widely distributed sister breed, the Jersey. Guernseys are noted for the production of milk of a pronounced yellow colour. The first Guernseys were exported to the United States in 1830, but it was not until 1870 that the export business became extensive. Numbers of Guernsey cattle are to be found also in England, Australia and Canada. The Royal Guernsey Agricultural and Horticultural society supervises the breed on the Island of Guernsey, maintaining two herdbooks, one for general registration and the other for advanced registry. The American Guernsey Cattle club was organized in 1877 and supervises the advanced registry system and pedigree registration of Guernseys in the United States.

The Brown Swiss.—The native home of the Brown Swiss is Switzerland. The breed is probably one of the oldest in existence. While these cattle are classified as a dairy breed in the United States, they are often considered as a dual-purpose breed for they are heavier boned and thicker fleshed than the cattle of the Channel Islands breeds. The colour of the Brown Swiss varies from light brown or gray to a dark shade of these colours. Brown Swiss cows are good, persistent milkers, producing milk of average quality as compared with other breeds of dairy cattle.

This breed has found favour in Italy, Austria, Hungary, United States, Mexico and the South American countries. Brown Swiss were first introduced into the United States in 1869. The Brown Swiss Cattle Breeders' Association of America, organized in 1880, supervises the registration of pedigrees and the register of production of Brown Swiss cattle in the United States.

The Ayrshire.—The Ayrshire breed originated in the county of Ayr in southwestern Scotland in the latter part of the 18th century and is considered to be the only special dairy breed to have originated in the British Isles. Native cattle of the county from which the breed takes its name appear to have been improved by crossing with other breeds to develop a type that would meet local conditions. Further mating and selection moulded the breed into its present form. The Ayrshire has very distinctive horns, which are long and curve outward, upward and slightly backward. The body colour varies from almost pure white to nearly all cherry red or brown with any combination of colours. The beef qualities of the breed are of secondary importance but among dairy breeds the Ayrshire ranks high as a beef producer. The distribution of the Ayrshire is wide, and exportations have been made to many countries. The breed is strongly represented in Canada and the northeastern part of the United States and is found also on the continent of Europe, in South Africa, Australia, New Zealand, Puerto Rico, Mexico and Central America. The Ayrshire Breeders' Association of the United States of America has been instrumental in fostering herd testing and a system of selective registration for approved sires of the breed.

Pedigree Cattle Breeding.—Many breeds and subbreeds of cattle are distributed throughout the world. On the continent of Europe alone, between 40 and 50 distinct breeds are described by French and German writers. Great Britain is the home of 11 breeds which have been exported to the United States, and in addition as many more minor breeds of local importance are described by English writers. The art of breeding seems to have begun in England about 1770 as the result of the work of Robert Bakewell. Bakewell was not only a pioneer breeder but is reported to have kept records and notes on the progeny of his cattle in order to show the progress made. The activities of the Collings brothers in improving the Shorthorn breed rank next to those of Bakewell in livestock improvement. The work begun by these breeders spread over Great Britain and had a lasting influence on livestock improvement throughout the civilized world. As the fame of British cattle spread to other countries, a demand was created for these improved breeds. Cattle were exported to other countries to found new herds and to improve the native cattle. Practically all present-day pure breeds of farm animals became breeds before the practice of registration, issuing of pedigrees and publication of their respective herdbooks was begun.

The development of breed registry associations in the United States differs somewhat from that of Great Britain where herdbooks remained open, for a time at least, to all animals that met certain requirements as to breed characteristics. The British practice tended to broaden the base of the breed. Cattle breeders continue to direct their efforts toward further improvement of breeds. Individual excellence and pedigree are accepted as only a part of breed improvement, as the essential test of an animal's breeding ability is in the performance of its progeny. Nonselective testing and the use of progeny-tested animals for breed improvement have received increasing attention by constructive breeders. The herd test and advanced register, or record-of-merit testing introduced by breeders of dairy cattle, the get-of-sire class, and slaughter test of the progeny of beef breeds are all useful tools in determining the utility value of registered cattle.

Conflicts of opinion on the use of impartial ratings with pedigrees are usually based on whether the information gained by such measures has enough practical usefulness to be worth the cost. Animal breeding is still practised largely as an art, with greater emphasis placed on selection by observation than on any other procedure. The setting up of well-defined types by early breeders, followed by rigid selection of breeding stock, was the basis of present breeds. Most of the subsequent improvement in the common livestock of the world has been accomplished by the mating of purebred sires to common females. Even in this

procedure best results are obtained when the females are selected with care and a high-quality registered sire is used. The effectiveness of this system of breeding is shown by the type of cattle found in the range area of the United States where most breeders have used registered bulls of the same breed for many generations. The result has been a uniform type of cattle in demand by feeders of the corn belt states. The mating of closely related animals has been highly successful in some cases and disastrous in others. Bakewell followed this practice, using animals of high merit, whereas Bates was not so successful. Twentieth-century breeders have followed this breeding practice only after using a sire so superior that a successor of equal or superior merit was difficult or impossible to find. Maintaining this standard of excellence by close breeding may also be possible when both parents are of high individual merit. Instances have occurred in which a new breed has been produced by crossing two or more well-established strains. In theory, the object of crossing two strains is to combine desirable characteristics possessed by each. Limiting factors are time and the expense of keeping the large numbers of animals necessary to fix the type. This system of breeding was followed in developing Polled Herefords, Polled Shorthorns, and the Santa Gertrudis breeds. A purebred sire has often been mated to purebred or high-grade females of another breed for the production of market animals. Crossing of two breeds generally produces offspring possessing greater vigour, ability to grow more rapidly, and ability to use feed somewhat more efficiently than either of the component purebred bloodlines.

After 1908 a number of co-operative dairy breeding associations were organized in the United States, the main purpose being to obtain for the members the services of registered proved sires at a reasonable cost. Another method of making extensive use of superior sires is by means of artificial insemination. Where artificial breeding associations were organized in the United States and trained technicians were available, this practice became a powerful medium of improving the masses of cattle of the country.

After 1900 there was growing appreciation of the value of scientific knowledge in breeding plans. A scientific approach to the study and practice of animal breeding has been made through the knowledge that the cell is the physical basis of inheritance and that all inheritance occurs in an orderly manner.

Nutritive Requirements.—The feed consumed by cattle is used for a number of functions, depending to some extent on the purpose for which the animal is maintained. The larger part of the feed is required for normal body functions; the remainder is available for growth, fattening, reproduction and lactation. Sources of nutritive energy, protein, fat, minerals and vitamins are essential for the proper nutrition of cattle. Investigations of maintenance and production requirements have been of a highly technical nature and the results have provided feeding standards. As good pasture has a high content of protein, minerals and carotene, and is an economical source of nutritive elements, pasture improvement has received much attention in the United States. Pasture not only tends to maintain fertility in the herd, but also provides the cows with a surplus of various known and unknown nutritive essentials that can be stored in their bodies and thus ensure them against such deficiencies that might occur from the feeding of low-quality roughage during the winter. Experienced feeders have found that a liberal feeding of protein is necessary for high milk production, with a tendency to supply this element in the form of a vegetable protein from green leafy legumes. Vitamin and mineral requirements have also received considerable attention. The minerals most likely to be needed to supplement feeds are common salt, calcium, phosphorus, iodine and iron. Other minerals are sometimes required. Calcium and phosphorus requirements are closely associated, since the two elements are stored together in nearly fixed proportions in the bones and secreted together in nearly fixed proportions in the milk. If either element is deficient in the feed, both bone building and milk secretion are hindered. Phosphorus deficiency is a more common cause of nutritive trouble with cattle than calcium deficiency, since the soil in some parts of the world is deficient in phosphorus, and the forage of these areas is deficient in this element. Where cattle subsist almost entirely on the range it is practical and sometimes less expensive to supply phosphorus and perhaps other minerals from sources other than grain and forage crops.

As with minerals, vitamins are perhaps of greater concern in rations for growing and breeding stock than for fattening cattle. Vitamin A appears to be the one most likely to be deficient in feeds for dairy cows, or for steers fattened in areas where green leafy forage and yellow grain are limited. Newborn calves have no reserve of this element but it is supplied by colostrum. Carotene, the yellow pigment of the plant from which vitamin A is formed in the animal body, occurs in close association with the green colouring matter of pasture plants and other green forage. As a rule, the greener the colour of the hay, the greater the amount of carotene, but hay stored for long periods tends to lose much of its carotene though still retaining most of its colour. Cattle must have an adequate supply of vitamin D to enable them efficiently to assimilate and utilize the calcium and phosphorus in their feed. It is believed that farm animals of all types generally receive an adequate supply of this vitamin by exposure to the sun's rays, depending on the intensity of the sunlight and its concentration of ultraviolet rays. Knowledge of nutritional requirements of cattle is very rapidly changing and still incomplete, and must constantly be reappraised as newer knowledge is obtained. (*See* also FEEDING STUFFS AND LIVESTOCK FEEDING.)

BIBLIOGRAPHY.—F. B. Morrison and others, *Feeds and Feeding; a Handbook for the Student and Stockman*, 21st ed. (1948); L. A. Maynard, *Animal Nutrition*, 3rd ed. (1951); R. R. Snapp, *Beef Cattle; Their Feeding and Management in the Corn Belt States*, 3rd rev. ed. (1939).

Management, Care and Handling.—The management and care of beef and dairy cattle are highly specialized practices. In the United States, for example, the feeding of beef cattle in the corn belt states, the production of feeder and grass-fat cattle on the ranges of the west, and the production of milk in the dairy sections of the northeast and middle-western states, all require a high degree of skill with different equipment and management practices. The range area is composed of plains and mountainous areas useful for grazing purposes. Practical ranch operation commonly involves attention to deferred and selective grazing to maintain the supply of forage, selection and culling of the breeding herd, controlled breeding, a well-arranged water supply and the production of winter feed where necessary. All of these practices are conducive to good condition of the breeding herd and a satisfactory crop of vigorous calves capable of making good gains.

On a well-managed ranch, a relatively high percentage of the investment is in the livestock rather than equipment. The range may be fenced or not, depending on the type of ranch. Corrals are used where large numbers of cattle are handled. In connection with the corral, a chute for holding cattle while being branded or vaccinated is usually a desirable investment. Range cattle are branded as a means of identification. Brands are recorded by the owner in the state where the ranch is located. Rounding up cattle or working the range is a time of great activity, especially when fat cattle are to be shipped, the breeding herd shifted to winter range, and calves separated from their dams to be sold as feeders or held on the ranch. The winter range is usually a pasture or range that offers some natural protection from winter storms and provides grass or browse that is suitable for winter grazing. When necessary, maintenance rations of cheap roughages or small amounts of protein supplement are fed during the winter or early spring.

The fattening of beef cattle in the United States is closely related to the production of calves and yearlings in the range area. The most important feeding area is the corn belt states of the middle west where calves or yearlings from the western ranges are fattened in dry lots. These cattle are fed corn and hay in feed bunks with some silage, salt, and minerals. Most cattle

feeders take it as a matter of course that cattle feeding cannot be made a successful enterprise without having hogs in the feed lot with the cattle. Inexpensive barns or sheds, feed racks and an adequate water supply are the most important items of equipment which with feed and labour go to make up the feeding operation.

While the production of feeder and grass-fat cattle in the range states is a highly specialized form of beef-cattle production in the United States, the maintenance of comparatively small breeding herds of registered cattle in many of the other states, as well as in the range area, requires a high degree of skill. Their care, management and breeding differ from those under which commercial range herds are handled. The registered cattle are produced primarily for breeding purposes and receive more attention and are fed more liberally as a rule than cattle produced primarily for slaughter. Breeding herds are made up of highly selected individuals conforming to the standards of the breed. Cows are bred to calve throughout the year, but most of the calves are born late in winter or early in the spring. During the summer months these calves run with their dams and may be fed grain in creeps while on pasture. Cows are usually maintained on pasture and roughage produced on the farm. Young cattle are given every opportunity to develop as considerable income is derived from the sale of young cattle, especially bulls, either at private sale or auction.

Dairy farming in the United States is usually distinct from the production of beef, but a certain amount of overlapping occurs. Approximately two-thirds of the dairy cows are cattle of specialized dairy breeds; the remainder consist of cattle of beef, dual-purpose, and mixed breeding. In commercial herds, replacements are commonly bought but some breeders grow their own replacements in order to improve production and lessen the danger of disease. Good cattle and modern methods of care and management are important elements in profitable dairying. Barns and equipment should be designed for producing and caring for milk efficiently and in a sanitary manner. The most common type of dairy barn in northern states is the two-story type with a loft for hay storage above the cows, whereas in the south where storage capacity is not so necessary, the one-story barn is more widely used. Practically every dairy farmer having a sufficient number of cattle to make the use of a silo profitable has one. Floors of dairy cattle barns are preferably of concrete, and the most common method of confining cows is with swinging stanchions. Water is often provided by means of automatic drinking fountains. Cows are milked twice daily, except in cases of advanced register or register of merit where three- and four-time milking may be practised. Milking machines are used successfully, especially where there is a labour shortage. On well-managed dairy farms each milking is weighed and butterfat tests are made at regular intervals. Most of the dairy breed associations have adopted herd-test plans under which all registered cows of the herd are tested. All these records are used as a part of the plan to show which cows are the most profitable. As feed is an important item in the cost of production, attention is given to the maintenance of pastures for summer feeding and the production of good-quality roughage for winter feeding. Good feeding, good breeding and the production of a sanitary product are the aims of the progressive dairyman.

CATTLE POPULATION AND WORLD TRADE

Estimates in round numbers of the cattle population of the world as averages for the years 1941–45 are shown in Table I.

Before the days of refrigeration as applied to transportation, most of the beef exports had been in the form of canned and cured meat. The first cargo of refrigerated beef was sent from the United States to England in 1874.

United States shipments of beef rose from 37,000,000 lb. in 1875–76 to 461,000,000 lb. in 1900–01. The marked expansion of beef exports from the United States from 1875 to 1900 was due in large measure to the settlement of new regions and the attendant expansion of livestock production in the United States and to the growing industrialization of Europe with the increasing demand for imported foodstuffs. But early in the 20th century an expanding domestic market, rapidly increasing competition from the southern hemisphere, and some expansion of livestock and meat production in northern and central Europe were responsible for a sharp decline in United States beef exports. By 1905 Argentina had surpassed the United States as an exporter of refrigerated beef and by 1914 United States exports of fresh beef had fallen to 6,000,000 lb. Exports of cured beef amounted to 23,000,000

lb. in that year. From 1921 to the early 1950s imports of beef into the United States were larger than exports in most years.

From 1924 to 1950 the United Kingdom was by far the greatest importer of live cattle, buying mostly from Ireland as it had not permitted imports from the continent for decades. However, the economic war waged by the two countries between 1931 and 1938 greatly reduced the number imported. Central Europe was a second deficit region for cattle. German supplies came chiefly from Denmark. Austria and Czechoslovakia, Italy and Greece were largely supplied from Bulgaria, Hungary, Rumania and Yugoslavia. United States imports came mostly from Canada and Mexico. (A. C. Ck.)

DISEASES OF CATTLE

The greatest hazard in rearing cattle, practically everywhere, is disease. The most destructive diseases are caused by bacteria, protozoa and filterable viruses, but fungi, parasites, poisons, malnutrition and metabolic disturbances also exact heavy tolls.

Foot-and-mouth disease (*q.v.*), or aphthous fever, probably is the most widespread and contagious of all infectious maladies of animals. Cattle and other cloven-footed animals, including swine, sheep and goats, are susceptible. The most rigid quarantines and restrictions of movements of animals and animal products frequently fail to control the spread of the malady. In the U.S., the immediate slaughter of affected and exposed animals completely eradicated the infection on six occasions after 1900. This procedure has been followed in England and adopted from time to time in some countries on the European continent, but the proximity of areas in which the disease is established is a constant hazard. The disease is prevalent in most of Europe, Asia, Africa and South America but (in the early 1950s) had not occurred in the United States since 1929. In countries where the disease is enzootic or where infection recurs from adjoining infected countries, total eradication has been found economically unfeasible and measures to control the infection include prophylactic vaccination, using variations of the product originally developed by S. Schmidt of Denmark and O. Waldmann of Germany in the late 1930s. Some 60,000,000 vaccinations of cattle, goats, sheep and swine were applied by the Mexico-United States Commission for Eradication of Foot-and-Mouth Disease in Mexico, where after a five-year campaign, the disease was finally eradicated in Sept. 1952. Approximately 1,000,000 animals were destroyed in the cooperative program financed by both countries.

Rinderpest (*q.v.*), or cattle plague, a highly fatal, contagious, filterable-virus disease, was widespread in the 19th century practically all over the world but has not occurred in North America. Vigorous eradication measures were widely applied, and it remains only in Asiatic countries and parts of Africa. The disease is characterized chiefly by severe gastrointestinal involvement. Control in countries where the disease is enzootic involves quarantines and use of preventive vaccines prepared with chemically inactivated tissue or virus attenuated by propagation in other species—goat, rabbit, chicken embryo.

Contagious pleuropneumonia, or lung plague, was prevalent in many countries before the 20th century. By means of quarantines and slaughter of affected animals, the disease has been eradicated from Europe and North America. It persists in Asia, Australia, and parts of Africa.

Tuberculosis (*q.v.*) in cattle is a widespread, chronic, bacterial disease caused by an organism closely related to that of human tuberculosis. Almost all mammals, including man, are susceptible to bovine tuberculosis. Cattle are relatively insusceptible, however, to the human and avian types of the infection. The bovine infection may be readily transmitted by infected milk and milk products. Pasteurization is an effective safeguard. The disease may be successfully controlled by quarantines and repeated application of the tuberculin test. The test is accurate to a high degree even in mildly affected animals. The infected animals may be placed in quarantine, thus reducing spread of the disease, or they may be slaughtered at once. The latter procedure, with quarantines and disinfection of infected premises, has been followed in the United States. The extent of bovine tuberculosis, formerly averaging about 5% and much higher in some areas, has been reduced to less than 0.5% in all parts of the U.S. Repeated testing is necessary, however, as long as any infection remains.

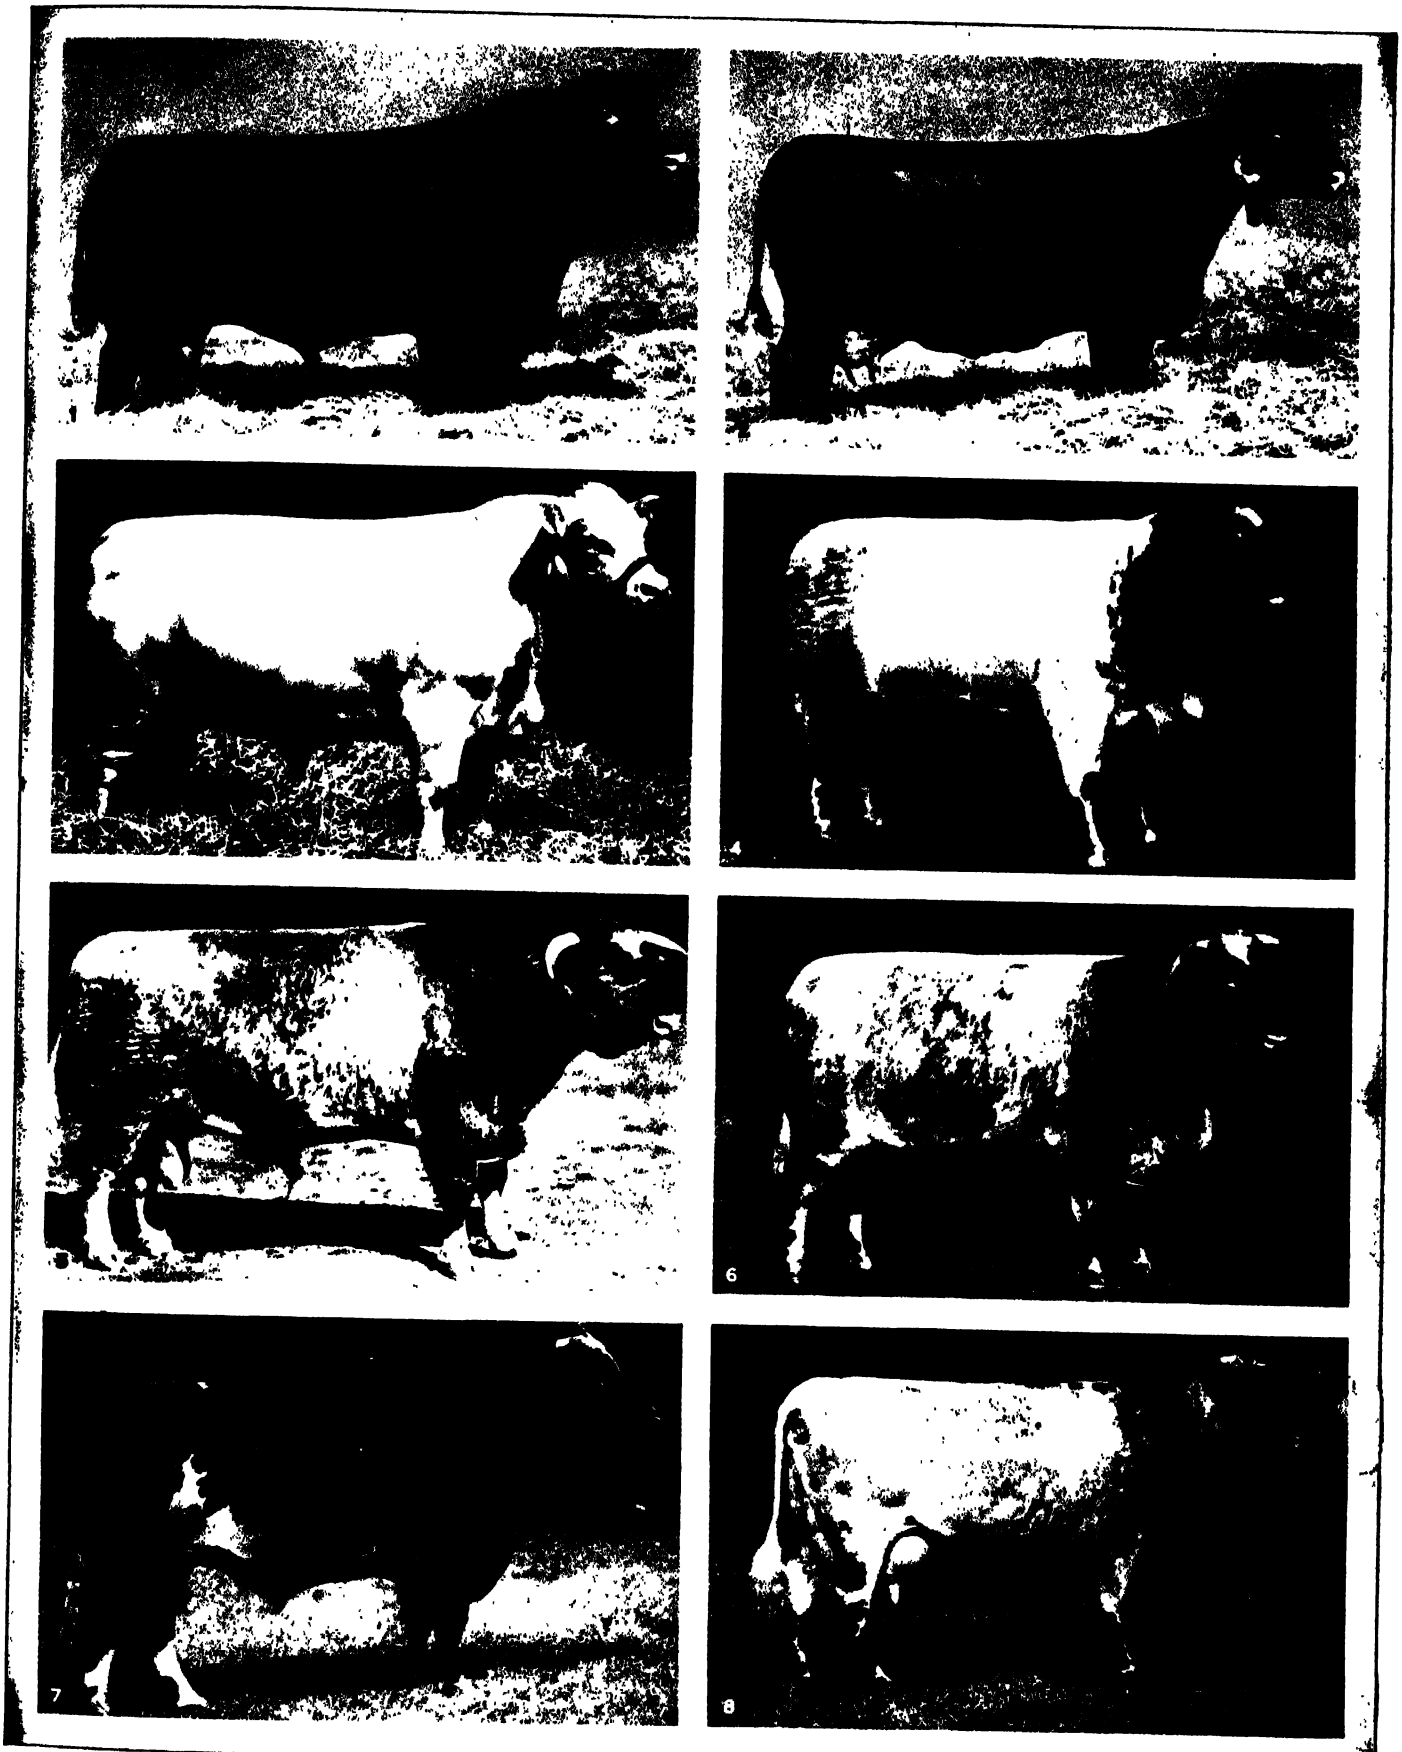
Brucellosis (*q.v.*), or Bang's disease, which is characterized by abortion and sterility, is a problem wherever breeding operations are conducted. The infection, caused by *Brucella abortus*, is prevalent to a greater or lesser extent throughout the world. Diseased animals are detected by tests of the blood or milk. Control may be effected by segregation or destruction of affected animals, with appropriate quarantine measures, with or without the aid of preventive vaccine. The most widely used vaccine is prepared with the so-called strain 19 of *Brucella abortus* which is especially useful in immature cattle. Man frequently contracts the infection, referred to as undulant fever, from infected cattle, swine or goats.

Mastitis, or inflammation of the udder, rivals all bacterial infections of dairy cattle in the aggregate loss it causes. It occurs in acute and chronic forms. Death rarely results but the infection, which may be due to streptococci, staphylococci or other organisms, causes alteration and material reduction of the milk secretion. Since the development of the sulfonamides and other antibiotic agents such as penicillin and streptomycin, considerable success has been achieved in treatment. The disease may be controlled by segregation of infected animals, sanitation and careful milking practices.

Johne's disease, or paratuberculosis, is a chronic disease of cattle, which causes considerable loss in Great Britain, North America and other parts of the world. The causative organism, *Bacillus* (*Mycobacterium*) *paratuberculosis*, produces a chronic dysentery which results in progressive emaciation and death in many cases.

Two acute, fatal, bacterial diseases of cattle are anthrax and black quarter (blackleg). These occur in quite definitely defined districts in widely separated parts of the world. In these enzootic areas, vaccination with biological products prepared from the respective causative bacteria is generally effective in control. Anthrax may be acquired by other animals and also by man.

Bovines, like other ruminants, possess a complex stomach having four compartments, the largest of which, the rumen, or paunch, has a capacity of as much as 50 gal. This anatomical peculiarity is responsible for frequent digestive disturbances. Bloat and impaction are common. Cattle also frequently suffer from perforations of the stomach by foreign metallic objects which are commonly ingested with the feed and cause death if they penetrate the heart sac.



Calves, especially those of the dairy breeds, commonly develop fatal enteric disorders unless special care in feeding and sanitation is taken.

Dairy cows are prone to develop metabolic diseases. Milk fever, or parturient paresis, is the commonest of these. It occurs usually just after parturition and invariably results in death if treatment is not given. Another such disease is acetonaemia, or ketosis, in which there are acidosis, subnormal quantities of sugar in the blood and faulty fat metabolism, with excess formation of ketones in the body.

Cattle may be afflicted with other diseases, infectious and otherwise, which cause considerable losses. These include actinobacillosis and actinomycosis, both commonly referred to as lumpy jaw; cowpox, which is closely related to smallpox; epithelioma (cancer eye), hyperkeratosis; infectious keratitis (pink-eye); leptospirosis; leukemia; pasteurellosis (haemorrhagic septicaemia); rabies; rickets; and trypanosomiasis.

Parasites of Cattle.—Parasites of cattle, belonging to such zoological groups as protozoa, worms and arthropods, cause extensive economic loss. Successful control measures generally consist in attacking the various parasites at vulnerable points in their life cycles.

The diseases caused by protozoa, or one-celled animals, are especially important in tropical and subtropical countries. Among the most destructive are piroplasmosis or tick fever, anaplasmosis, surra and nagana. All these diseases are caused by minute parasites that live in the red blood cells or in the blood stream, and are usually transmitted by blood-sucking arthropods such as ticks and flies; they are generally characterized by fever and destruction of the red cells. The monetary loss from these diseases is very great. However, by mid-20th century practically all of these losses had been eliminated in the United States through eradication of cattle ticks by systematic dipping of ticky cattle in standardized arsenical dips. Control of other protozoan blood diseases, especially those transmitted by flies, has been less satisfactory.

Other protozoan diseases of cattle are coccidiosis and venereal trichomoniasis. Coccidiosis is an intestinal disease characterized by bloody diarrhoea and emaciation. It is caused by sporozoan parasites that infect the inner lining of the intestine. The infection is largely in calves and is controlled by strict sanitation. Venereal trichomoniasis is caused by a small flagellate organism that is transmitted through coitus. Infection results in early abortion, sterility and other breeding difficulties.

The worm parasites are flukes, tapeworms and roundworms. The common liver fluke (*Fasciola hepatica*) lives in the bile ducts; it causes extensive damage to the liver and general unthriftiness of the infected animal. The complicated life history and control measures are the same as those discussed under diseases and parasites of sheep. (*See* SHEEP: *Parasites of Sheep.*)

Several species of tapeworms infest the digestive tract but these worms do not appear to cause extensive injury. The larval or bladderworm stage of the common tapeworm (*Taenia saginata*) of man occurs in the muscles and causes a condition known as "measly beef." Cattle acquire the infestation by swallowing the eggs while grazing on pastures that have been contaminated by excrement from tapeworm-infested persons.

Important roundworm parasites are lungworms, stomach worms and intestinal threadworms of which there are numerous species. All these worms are acquired by picking up the infective larvae while grazing. Roundworms cause unthriftiness, anaemia and digestive disturbances, especially diarrhoea. The injurious effects are most pronounced in calves and in animals under two years of age.

Sanitation, pasture rotation and avoidance of overstocking tend to control worm parasites. Medicinal treatment with anthelmintic drugs, especially phenothiazine, is of value in controlling stomach and intestinal roundworms.

The arthropod parasites include the ticks, mites, lice and flies. Aside from ticks and certain flies that transmit tick fever, anaplasmosis and other protozoan blood diseases, the most injurious arthropod parasites are the warble flies, *Hypoderma lineatum* and *H. bovis*. These flies lay their eggs on the legs of cattle. In a few days the eggs hatch and the young larvae penetrate the skin. They then migrate through the tissues of the body and eventually reach the back. Here the larvae or grubs, as they are sometimes called, complete their growth and produce swellings. The skin over each swelling becomes perforated and the holes so formed permit the larvae to breathe and to escape when they have completed their growth.

A somewhat similar fly larva (*Dermatobia hominis*), commonly referred to as nuche or gusano, infests cattle in Central and South America. The adult fly does not deposit its eggs directly on the skin as do the warble flies, but lays them on the bodies of mosquitoes and other bloodsucking insects. The eggs hatch and the larvae crawl onto the skin when the insect is feeding.

Hatching is stimulated by the warmth of the victim's body. Ox warbles may be controlled to some extent by manual extraction of the grubs or by the use of dusts, dips or washes containing insecticidal substances such as rotenone.

Other arthropods such as ticks, mites, lice and flies inflict considerable injury to animals by abstracting blood and causing irritation to the skin.

Such parasites living habitually on their hosts may be controlled by the use of insecticidal dips, washes or dusts; flies are best controlled by destruction of their breeding places.

(E. W. PE.; X.)

CATULLUS, GAIUS VALERIUS (84?–54 B.C.), the greatest lyric poet of Rome. As regards his names and the dates of his birth and death, the most important external witness is that of Jerome, in the continuation of the Eusebian *Chronicle,* under the year 87 B.C., "Gaius Valerius Catullus, scriptor lyricus Veronae nascitur," and under 57 B.C., "Catullus xxx. aetatis anno Romae moritur." There is no controversy as to the gentile name, *Valerius.* Suetonius, in his *Life of Julius Caesar* (ch. 73), mentions the poet by the names "Valerium Catullum." Other persons who had the *cognomen* Catullus belonged to the Valerian gens, *e.g.* M. Valerius Catullus Messalinus, a *delator* in the reign of Domitian, mentioned in the fourth satire of Juvenal (l. 113).

Inscriptions show, further, that *Valerius* was a common name in the native province of Catullus, and belonged to other inhabitants of Verona besides the poet and his family (Schwabe, *Quaestiones Catullianae,* p. 27). Scholars have been divided in opinion as to whether his *praenomen* was *Gaius* or *Quintus,* and in the best MSS. the volume is called simply *Catulli Veronensis liber.* For *Gaius* we have the undoubted testimony, not only of Jerome, which rests on the much earlier authority of Seutonius, but also that of Apuleius. In support of *Quintus* a passage was quoted from the *Natural History* of Pliny (xxxvii. 6, 81). But the *praenomen* Q. is omitted in the best MSS., and in other passages of the same author the poet is spoken of as "Catullus Veronensis." The mistake may have arisen from confusion with Q. Catulus, the colleague of Marius in the Cimbric War, himself also the author of lyrical poems.

Internal evidence shows that certain poems were written two or three years after 57 B.C., the date of Catullus' death according to Jerome. Thus cxiii. was composed in 55 B.C., lv. either in that year or later, while xi., xxix., xlv. all appear to be written after Caesar's first invasion of Britain (55 B.C.). He is described by Ovid as "hedera juvenalia cinctus Tempora,"—a description somewhat more suitable to a man who dies in his thirtieth year than to one who dies three or four years later. Since no poem is certainly later than 54 B.C., it is best to retain Jerome's reckoning of Catullus' age as 30 years but to suppose him to have lived from 84 to 54 B.C.

Jerome's statement that Catullus was born at Verona is confirmed by other authorities. His father was important enough to act as Caesar's host, and it was probably at or near Verona that Caesar accepted the poet's apologies for the attacks on himself and Mamurra (xxix. and lvii.; *see* Suetonius *Jul.* 73); xciii. may represent Catullus' reply to earlier advances on Caesar's part. The poet's attitude was not due to republican sentiment, but the result of personal animosities. In xxix. he arraigns Pompey along with Caesar, and in xi. he recognizes the latter's greatness.

Catullus' complaints of poverty are not to be taken very seriously. He possessed a villa at Tibur as well as a retreat at Sirmio on Lake Garda, and the poems prove that he had the means to figure in the best society. Still his purse was often no doubt, as he says, "full of cobwebs" (xiii. 8).

On reaching manhood Catullus was sent to try his fortune at Rome. The premature death of his brother in Asia Minor seems to have recalled him to Verona (*cf.* lxviii.). In 57 B.C. he made a belated attempt at a public career by accompanying Memmius, the patron of Lucretius, to Bithynia, of which province Memmius had been appointed governor. His hopes of lining his purse at the expense of the provincials were not realized, and in the spring of 56 B.C. he left Nicaea (xlvi.) and returned to Italy, perhaps on his own yacht (*cf.* iv.); *en route* he visited his brother's tomb in the Troad (ci.). His delight at seeing Sirmio once more is charmingly expressed in xxxi. The poems show that his last years were divided between Verona and Rome. As a Transpadane, Catullus found many compatriots in the capital, and among them several representatives of the new movement in poetry led by Valerius Cato.

himself a native of Cisalpine Gaul. The poems reveal him on terms of intimate friendship with certain of the younger members of this circle; *e.g.*, Calvus (xiv., l., liii., xcvi.), Cinna (x., xcv., cxiii.), Cornificius (xxxviii.). He appears to have been acquainted with the two leading orators of the day—Cicero (xlix.), and Hortensius (lxv. and xcv.). Among friends of less eminence he counted a Caelius (lviii.) whom some identify with Cicero's protégé M. Caelius Rufus, thinking that lxix. and lxxvii. addressed to a Rufus, refer to the same man; this is possible, but in that case another Caelius must be meant in c., since Cicero's friend was not a native of Verona. Particularly dear to Catullus, but otherwise unknown to us, were two friends Veranius and Fabullus (ix., xii., xiii., xxviii., xlvii.), while in i. he dedicates his *libellus* to the biographer and historian Cornelius Nepos, who in after years left it on record that in his opinion Catullus and Lucretius were the two greatest poets of that period (Nepos, Life of Atticus xii., 4). Among Catullus' enemies the most furiously attacked in the poems—apart from Caesar and his lieutenant—are the pair Furius and Aurelius (xv., xvi., xxi., xxiii., xxiv., xxvi.), and one Gellius, who is the target of no fewer than seven epigrams. Other victims of his invective are Ravidus (xl.) and Rufus (*see* above), his rivals in love; a freedman Thallus (xxv.); a ridiculous fop Egnatius (xxxvii., xxxix.). To a false friend Alfenus he writes more in sorrow than in anger (xxx.). The most important influence in Catullus' life was that of his mistress Lesbia. Her real name was Clodia (Apuleius, *Apol.* 10); Catullus chose the pseudonym for its connection with Sappho (li., a translation of a famous ode of Sappho, was perhaps a first tribute to his mistress' charms). There can be little doubt that Clodia was the notorious sister of the demagogue, married in 63 B.C. to Q. Metellus Celer and suspected of responsibility for his death in 59 B.C. Cicero mentions her several times in his Letters, and has left a graphic picture of this dangerous beauty in the speech (*Pro Caelio*), in which he defended M. Caelius Rufus (*see* above), also one of her lovers, against the charge of having tried to poison her. Though Cicero writes as an advocate and Catullus as a lover, their descriptions are not inconsistent, and the final proof of identity is contained in lxxix., the *Lesbius* of which poem clearly covers a Clodius, not, however, the demagogue P. Clodius, but Sex. Clodius, a kinsman and associate of Publius, whom rumour represented as having relations with Clodia (Cicero, *De Dom.* 25) similar to those attributed to *Lesbius* by Catullus. A recent attempt to identify Lesbia with a younger sister and namesake of Metellus' wife, who married L. Lucullus and was divorced by him for alleged relations with her brother, appears unconvincing. Catullus was Clodia's lover during Metellus' lifetime (*cf.* lxxxiii.); the husband's death apparently brought other rivals on the scene, and Catullus' allegiance had been sorely tried before he left for Bithynia, but xi., the final renunciation, is subsequent to his return (*see* above). The data do not suffice to fix the course of the liaison more exactly.

Catullus' poetical activity began soon after his assumption of the *toga virilis* (*cf.* lxviii. 15–17); references in the poems suggest that he sometimes published his pieces separately or in small groups (*cf.* i. 4; xvi. 3.; xlii.; xliii. 7; liv. 6). Later (*cf.* i.) he formed a collection of his compositions and dedicated it to Cornelius Nepos, but it is a moot point what this *libellus* contained, whether it was identical with the present collection, and, if not, how the latter was formed. As arranged in the mss., the poems fall into three sections, viz., (1) i.–lx., shorter lyric pieces, (2) lxi.–lxviii., longer poems in a variety of metres, (3) lxix.–cxvi., elegiac epigrams. The hypothesis most in favour recently is that our present collection was formed in outline by Catullus himself before his death, and that afterwards his literary executors inserted in the groups so arranged sundry other material discovered among his remains, including unfinished pieces like xiva. and lx.

Though Catullus was an Italian of the Italians in character and temperament, it is impossible to appreciate his poetry correctly except in relation to Greek and more particularly Alexandrian poetry. Like that of the other *novi poetae*, his work has two aspects. On the one hand we have the shorter pieces in which any and every emotion of the moment finds instant expression, on the other the poems which earned Catullus the title of *doctus*, considerably longer than his *nugae* but short when compared with the Annales of a Volusius (xxxvi., xcv.). The poet's debt to Alexandrian models in these longer compositions, though hard to control to-day owing to the fragmentary survival of later Greek poetry, is universally admitted. Catullus himself declares lxvi. to be a translation from Callimachus (*cf.* lxv. 16); lxiv. is cast in the mould of a Hellenistic *epyllion;* lxviii., a mixture of the personal and narrative elegy, framed as a letter to a friend, also has Alexandrian forbears; lxii. adapts an epithalamium of Sappho after the manner of the later Greeks; even lxiii. (the *Attis*) which gives an impression of striking originality probably follows in the track of Callimachus or some other Alexandrian. The most original of these longer poems is probably lxi., the epithalamium for Manlius Torquatus and Vinia (or Iunia) Aurunculeia, since here Catullus has tried to fuse the native *versus Fescennini* with the Greek *hymenaeus;* it contains touches, *e.g.*, 216–220, marked by a tenderness unknown otherwise before Virgil. Even in the *nugae* Catullus' debt to Greece is greater than was realized till recently. Just as the life of the γεώτεροι with its interest centred on love and letters had been anticipated by that of the later Greeks (compare l. with the lines of Hedylus [*flor. circ.* 290 B.C.] preserved in Athenaeus xi. 473a; *see* also xxxv. and xxxviii.), so the forms, lyric παίγνιον and elegiac epigram, to express these emotions, had been fixed by the same predecessors. Hellenistic lyric only surviving in meagre fragments, Catullus' originality appears greater here than in his elegiacs which we can compare with the epigrams of the Greek Anthology, but metre (especially the scazon iambic and phalaecan hendecasyllabic), subject-matter, and often phrasing indicate his obligations. The poems on Lesbia's sparrow (ii. and iii.) and that on the yacht (iv.) had Hellenistic prototypes, and an Alexandrian element crops up even in such an ardent love-poem as vii. (*cf.* ll. 3–6). Nevertheless it is in these shorter pieces that Catullus is most Roman and most himself. The attacks on the smaller fry who had incurred his displeasure often revolt us to-day by their gratuitous obscenity, but the *iambi* on Caesar and his associates, which recall but far surpass in bitterness the popular lampoons current at the expense of the *imperator unicus*, were justly considered by their chief victim to have branded him with *perpetua stigmata*. On the other side the Lesbia cycle cannot be paralleled in ancient literature for sincerity of passion, passing through all the stages of joyous contentment, growing distrust, and wild despair to the poignant adieu of the disillusioned lover.

The best edition of Catullus is that by W. Kroll (Leipzig, 1923). The best English commentary is that by R. Ellis (2nd ed., 1889). Neither the current Oxford text (1904) nor the Teubner (1923) can be considered satisfactory. Volume vi. of the Loeb Classical Library (1912) contains a text and translation of Catullus along with Tibullus and the *Pervigilium Veneris*. The most recent translations into English are by Sir William Marris (1924) and F. A. Wright (n.d.). *See* also H. A. J. Munro, *Criticisms and Elucidations of Catullus* (2nd ed., 1905); K. P. Harrington, *Catullus and his Influence* (1923); Frank Tenney, *Catullus and Horace* (1928). (E. A. B.)

CATULUS, the name of a distinguished family of ancient Rome of the gens Lutatia. The following are its most important members:

1. GAIUS LUTATIUS CATULUS, Roman commander during the first Punic War, consul 242 B.C. With a fleet of 200 ships, he occupied the harbours of Lilybaeum and Drepanum. The Carthaginian relieving fleet was totally defeated off the Aegates Islands, March 10, 241, and Catulus shared in the triumph, though, owing to a wound, he took no part in the operations. (*See* PUNIC WARS: First, *ad fin.*)

2. QUINTUS LUTATIUS CATULUS, Roman general and consul with Marius in 102 B.C. In the war against the Cimbri and Teutoni (*qq.v.*) he was sent to hold the passage of the Alps, but was forced back over the Po (*see* MARIUS, GAIUS). In 101 the Cimbri were defeated on the Raudine plain, near Vercellae, by the united armies of Catulus and Marius. The chief honour being ascribed to Marius, Catulus became his bitter opponent. He sided with Sulla in the civil war, was included in the proscription list of 87, and committed suicide. He was distinguished as an orator and writer, and is said to have written the history of his consulship and the

Cimbrian War. Two epigrams by him have been preserved and are published in W. W. Merry's *Fragments of Roman Poetry* (Oxford, 1898, p. 173). *See* Plutarch, *Marius, Sulla;* Appian, *B.C.* i, 74; Vell. Pat. ii, 21; Florus iii, 21; Val. Max. vi, 3, ix, 13; Cicero, *De Oratore*, iii, 3, 8; *Brutus*, 35.

3. QUINTUS LUTATIUS CATULUS (*c.* 120–61 B.C.), son of the above, was a consistent supporter of the aristocracy. In 78 he was consul with Marcus Aemilius Lepidus, who proposed the overthrow of the Sullan constitution. Catulus vigorously opposed this, but Lepidus marched on Rome at the head of an army. He was defeated by Catulus and Pompey and fled to Sardinia. In 67 and 66 Catulus unsuccessfully opposed the Gabinian and Manilian laws, which conferred special powers upon Pompey. He consistently opposed Caesar, whom he tried to implicate in the Catilinarian conspiracy. Caesar, in return, accused him of embezzling public money during the reconstruction of the temple on the Capitol. Catulus's supporters rallied round him, and Caesar dropped the charge. Although not a man of great abilities, Catulus exercised considerable influence through his political consistency and his undoubted solicitude for the welfare of the state.

See Sallust, *Catilina*, 35, 49; Dio Cassius xxxvi. 13; Plutarch, *Crassus;* Suetonius, *Caesar*, 15.

CAUCA, a department of Colombia, on the Pacific coast. Area 11,660 sq.mi. Pop. (1938 census) 356,040; (1951 est.) 468,790. The Western Cordillera, traversing nearly its whole length from south to north, and the Central Cordillera, forming a part of its eastern frontier, give a very mountainous character to the region. It includes, besides, the fertile and healthful valley of the upper Cauca, and a part of the coastal plain. The region is rich in mines and valuable forests, but its inhabitants have made very little progress in agriculture because there are not adequate transportation facilities. Capital of department is Popayán, pop. (1947) 35,960.

CAUCASIAN AREA, NORTH. A natural area and former province in the Russian Soviet Federated Socialist Republic. Boundaries are: W., the Ukraine, the Sea of Azov and the Black sea; S., the Azerbaijan and Georgian republics; E., the Caspian sea; N., the Stalingrad and Voronezh regions. Area, 110,969 sq.mi. Pop. 8,324,788; urban 1,408,085, rural 6,916,703. The following are linked to it administratively: the Kabarda-Balkaria, North Ossetian, Checheno-Ingushetia and Daghestan autonomous republics, and the Adygei, Cherkess and Karachaev autonomous regions. Most of the area is a fertile plain, which has always been a zone of movement of peoples, owing to its situation between the Black sea and the Caspian, with the Caucasus on its southern flank. It formed a link between the Mediterranean civilizations which established trading colonies there, the Persian and Turkish empires of Asia Minor, the Tatar and Mongol steppe peoples, and the Russians from the northwest, all attracted by its fertility and its trading possibilities. In 1926 the varying elements in the population included Russians (Great Russians, Ukrainians and White Russians) 83.38%, Chechens, 2.72%, Ossetians 2.03%, Armenians 1.98%, Kabardians 1.85%, Greeks 1.14%, Germans 1.06%, Cherkess 1.03%, with Ingushes, Karachaevs, Jews, Poles, Kalmucks, Georgians, Tatars, Turks, Persians, Moldavians, Estonians, Czechs and Lesgians. In spite of these varied elements, the area has a certain economic unity: it is essentially an agricultural area undergoing a process of industrialization, and has an important export trade. In varying forms this export trade dates from a great antiquity. The west and southwest, with rich black earth soils, have intensive agriculture, market gardening and dairying, and a good net of communications; proximity of the Black sea and the Caucasus leads to increased rainfall and modification of summer heat and winter cold, abundance of streams and a longer vegetative period (*i.e.*, number of days with a temperature above 40° F.); in the Black sea area there are 275 days, and in Krasnodar, Maikop and Armavir 250, as against 200–210 days in the Donetz and Shakhtinsk areas. Towards the north and in the east the climatic influences are Continental, with drought conditions, and in the east the soils are chestnut-coloured (favourable to the growth of summer wheat in wet years), with about 10% saline and arid sands unfit for agriculture. The chief crops are summer wheat in the northern provinces, a hard variety in demand on the world market for flour and macaroni, etc., winter wheat in the wetter southwest districts, barley, maize, rye, millet and oats. Sunflower seed, providing food, oil, fuel and potash is increasingly cultivated in the Kuban area, as are crops new to the region such as cotton, soybeans, castor-oil plants and kenaf. Swampy tracts along the Kuban are being reclaimed and sown to rice, a crop also new to the region. There are vineyards in the Don, Black sea, Kuban and Terek areas: the Don wines are good, but the Kuban and Terek wine is sharp. Vineyards are being extended in the sandy areas along the Don. Tobacco is cultivated in the Kuban and Black sea regions. In the southwest Kuban and near the great cities and health resorts market gardening (especially of melons, pumpkins and potatoes) is prosperous. Agriculture suffered severely during World War I and was slowly recovering during the post-World War I years.

Cattle rearing is decreasing, and is mainly limited to the dry steppe and the hill pasture meadows. The stock of horses greatly diminished between 1914 and 1921. Horses are bred in Kuban and Kabardia and by the steppe nomads. In Kuban they are used as working animals. The gray Black sea cattle, related to the Ukrainian cattle, are the best working oxen, and are bred and used in the north and near Maikop. Dairy cattle (German) are in demand near the cities, while the Kalmucks breed the best cattle for meat. Formerly in the Stavropol steppe and the Salsk area there were 4,000,000 head of merino sheep, but they were catastrophically destroyed between 1914–21 and the number dropped to only 300,000 or 400,000. Goats are kept for milking, especially in the hill areas. Pig breeding recovered its pre-World War I level, especially in the Kuban and the maize zone of the foothills. Hens, geese, ducks and turkeys numbered 11,000,000 before World War II, and eggs, feathers, down and live and dead birds are exported (mainly to the home Russian markets). In Kuban, Terek and the foothills the long, warm summer and the flora favour beekeeping, and much good wax is exported.

The steppe and much of the plain is treeless, except near the streams and along the Don valley (oak and elm). On the foothills patches of mixed steppe and forest lead to the continuous beech, oak, hornbeam, ash, maple, lime and elm forest, above which are pines, birches and silver firs, with Alpine meadows higher still. The Black sea slopes yield yew and chestnut. The government is controlling timber felling on the foothills in view of the importance of tree growth in regulating the streams and in fixing the soil. In the higher regions much timber is neglected because of lack of labour and lack of transport. Of the timber, most goes to the treeless steppe, the markets of the near east and the Mediterranean. The silver fir is used in the home region for cellulose manufacture.

Fishing for bream, carp, herring, mackerel, sturgeon and anchovy is carried on in a primitive way, but suffers from lack of refrigerators and of quick transport. The mineral wealth consists of the Grozny and Maikop-Taman naphtha beds, the silver, lead and zinc ores of Alagir, south of Orjonikidze, lead ore on the upper Kuban, anthracite in the Shakhtinsk area and south of Batalpashinsk, and coal and iron ore on the north shore of Azov. Some of the mines are worked by peasant artels. The chief manufactures are foodstuffs (flour and fish, fruit and vegetable preserves) especially in the Kuban, naphtha refining at Grozny, Tuapse, Maikop (aviation benzine), cement at Novorossiysk, tobacco at Rostov, Krasnodar, Armavir and Orjonikidze, agricultural machinery at Rostov, Taganrog and Sylin, leather at Taganrog and Maikop, sugar near Armavir and in the Kuban. Maize products (brandy, starch and flour), textiles (wool, cotton, stockings, ropes), soap, potash, bricks, glass, tiles and paper are also manufactured and there are printing works at Rostov and other towns. Side by side with the factory industries go the koustar (peasant) industries and in the flour milling and oil pressing they produce 45% of the total. The chief towns in order of size of population in 1939 are: Rostov-on-Don 510,253; Krasnodar 203,946; Taganrog, Grozny, Shakhty, Orjonikidze (Vladikavkaz), Novorossiysk, Armavir, Maikop, Voroshilovsk, Pyatigorsk, all over 50,000; and Batalpashinsk, Millerop and Salsk.

These towns and their population are an indication of the

marked industrial development of the area, as is the fact that naphtha and not wheat is now the chief export. But agriculture is still, as in the past, the chief occupation of the area. In the internal life of the area it affects directly the welfare of four-fifths of the population and indirectly its development affects the remaining one-fifth, regulating markets, causing seasonal over-freightage of the transport network (railways, ports, elevators and refrigerators) and supplying the raw material for the factories and the food for the workers. The importance of the North Caucasian area in the economy of the U.S.S.R. as a source of supply of wheat and raw material is recognized by the government.

A canal was being constructed in 1944 to transfer part of the waters of the Kuban, which has an oversupply, to the Manich, a tributary of the lower Don. This canal was to irrigate 2,500,000 ac. of land. Eventually the Manich waterway will be extended to the Caspian sea, 390 mi. away. Its level will be maintained by a canal from the Terek which will also generate water power and irrigate a large expanse of steppe land.

CAUCASIAN LANGUAGES. This term is applied to the languages used on the Caucasian isthmus which do not belong to the Indo-German, or to the Semitic, or to the Turco-Mongolian family. They are divided into three groups—the *East Caucasian*, the *West Caucasian* and the *South Caucasian*. The East Caucasian group can be divided into eight branches: 1. The Chechen branch (the chief being the Chechen language of the middle course of the Terek and Daghestan); 2. Avaro-Andi (12 languages in West Daghestan, the chief being the Avar language); 3. Darghi (East Daghestan); 4. Samur (South Daghestan, the chief being the Kuri language, near Derbent); 5. Lakk or Kasi-Kumuk (Central Daghestan); 6. Artchi (one village in Central Daghestan); 7. Hinalugh (one village near the mountain Shah-Dag); and 8. Udi (two villages near the town Nukha). The West Caucasian languages have three branches: 1. Abhaz—region of Sukhum-Kale; 2. Ubykh—formerly dominant in the region of Sotchi, but now spoken only by a few families in Asia Minor; 3. Adyghe, with two dialects—Kabardi (in the so-called Kabarda, principal town Naltchik) and Kiakh or Cherkess (region of Kuban and the Caucasian shore of the Black sea). The South Caucasian languages are: 1. Georgian with its dialects; 2. Mingrelian and Laz; 3. Svanetian.

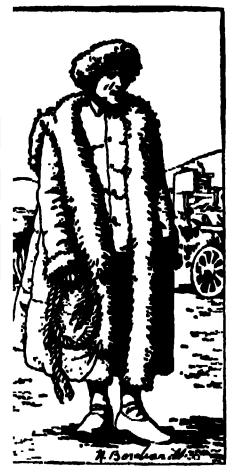
East Caucasian and West Caucasian are related and may be considered as two branches of the North Caucasian group. The relationship between this and the South Caucasian group has not, as yet, been scientifically proved, and in the present state of our knowledge the North Caucasian and South Caucasian groups must be considered as separate.

The North Caucasian languages are distinguished by an extraordinary abundance of *consonants*, which in Cherkess are 57 in number. Very characteristic of the phonetic system of North Caucasian languages are the lateral consonants, which convey the impression of combinations *kl, gl, thl;* then a great number of consonants of the type *k*, pronounced in the deep back part of the palate, etc. This superabundance of consonants is moderated in the East Caucasian group where consonants rarely come into contact with each other; but in West Caucasian languages the contact and combination of consonants occur very frequently, and the most complicated combinations, very difficult to pronounce, are admitted.

In the East Caucasian languages substantives are divided into classes or "genders"; their number varies in different languages (from two to six). In most cases, neither from the meaning of the word nor from any outward formal symptom is it possible to know to which class the substantive belongs. Very often the same substantive belongs in the singular to one class and in the plural to another. A consonant, specific for each group (*w, b, d, r, y*) is added as prefix, infix or suffix to the adjectives, verbs, pronouns, adverbs, etc., connected with the substantive. For example, the Avars say: *"Dow tchi wugo roqow"*—this man is in the house; *"Dob keto bugo roqob"*—this cat is in the house; *"Doy thladi Yigo roqoy"*—this wife is in the house. Substantives, adjectives and pronouns are declined; an extraordinary number of cases is used to express ideas that in other languages are expressed by a combination of words with prepositions. The Tabassaran language has 35 cases. The system of declension is based on the opposition of *Casus Agens* to *Casus Patiens*. The Casus Agens is used for the logical subject of transitive verbs, and Casus Patiens for the logical object of transitive and logical subject of intransitive verbs. The outward distinction between Casus Agens and Casus Patiens is expressed in a different way by different substantives. Thus, in the Kuri language *Lam*—"ass"—has Agens *Lamra* and *ghum*—"smoke"— has Agens *ghumadi*. All other cases are derived from the Agens by adding different endings. The plural is also formed differently from different substantives, so that the declension of substantives in East Caucasian languages is full of irregularities. The same is true of conjugation in most of these languages. The verbal root, *i.e.*, the invariable part of all verbal forms, consists mostly of one consonant. Before it are the prefixes, indicating the aspect of the verb (*i.e.*, whether the action is considered as a lasting process or as a concluded action) and the gender signs mentioned above agree with the Patiens of the sentence. After the root consonant come the elements, indicating time, mood and sometimes the person. There are many verbal forms and the difference of their meaning is often very subtle and difficult to define. The East Caucasian languages have therefore a complicated grammar with a great abundance and prodigality of forms. The same prodigality is found in the vocabulary; there are for instance special adverbs to indicate such notions as "five years ago," "four days later," etc.—these words having nothing in common with the corresponding numerals.

In the West Caucasian languages, declension is reduced to a minimum; the Adyghe and Ubykh languages have only three cases, the Abhaz has no declension at all. There are fewer verbal forms than in the East Caucasian languages. The vocabulary is poor, so that the simplest notions are expressed by compound words, *e.g.*, in Adyghe the beard is designated as "tail of the mouth," etc. The characteristic peculiarity of West Caucasian languages is a fondness for combining words. Notwithstanding these differences between East and West Caucasian languages, there are still important similarities in both these groups—viz., in the most elementary words, personal pronouns, numerals, simple verb roots, etc., so that there can be no doubt as to their relationship. There are also isolated similarities in the grammar, for instance the opposition of Casus Agens to Casus Patiens, traces of the different classes of substantives, etc.

The phonetic system of South Caucasian languages is simpler than that of the North Caucasian; there is a striking fondness for the agglomeration of consonants (*e.g.*, the Georgian, *mghwdl* is genit. for "priest"). There is only one gender. The declension is rich in case forms, but their formation is regular. The verb has a developed conjugation; the means of expressing personal forms through combination of certain prefixes and suffixes is complicated. In the South Caucasian languages the agreement of the verb with its subject and object varies with the tenses of the verb. In the present the subject is in the nominative and the object in the dative-accusative. In the Aorist the subject is in a special case (Agens?) and the object in the nominative, in the perfect the subject is in the dative and the object in the nominative.



Georgian alone has an ancient written literature, beginning with the 5th century A.D., and in recent years books and newspapers have begun to appear in other Caucasian languages.

BIBLIOGRAPHY.—Literature on North Caucasian languages is to be found in Meillet and Cohen's, *Les Langues du Monde* (Paris, 1924) and A. Dirr, *Einführung in das Studium der Kaukasischen Sprachen* (Leipzig, 1928). For *Georgian*, A. Dirr, *Theoretisch-praktische Grammatik der modernen Georgischen (Grusinischen) Sprache* (No. 81, Hartleben's *Kunst der Polyglottie* Series); F. N. Fink, *Die Haupttypen des Sprachbaues*, p. 132–149 (Leipzig, 1910). (N. S. T.)

CAUCASUS, a mountain range, stretching north-west to south-east from the Strait of Kerch (between the Black sea and Sea of Azov) to the Caspian sea, over 900m. long and varying from 30 to 140m. in width. In its general uniformity of direction, its comparatively narrow width, and its well-defined limits towards both south and north, it presents a closer analogy with the Pyrenees than with the Alps. The range, like the Pyrenees, maintains for considerable distances a high elevation, and is not cleft by

natural passes, as in the Alps. In both ranges some of the highest summits stand on spurs of the main range, not on the main range itself, *e.g.*, Mts. Elbruz and Kasbek, Dykh-tau, Koshtan-tau, Janga-tau and Shkara. For purposes of description it is convenient to consider the range in four sections, a western, a middle with two subsections and an eastern.

Western Caucasus.—This section, extending from the Strait of Kerch to Mt. Elbruz in 42° 40′ E., is over 420m. long, and runs parallel to the north-east coast of the Black sea and only a short distance from it. Between the main range and the sea there intervene at least two parallel ranges separated by deep glens, and behind it a third subsidiary parallel range, likewise separated by a deep valley, and known as the Bokovoi Khrebet. All these ranges are crossed by numerous glens and gorges, and the rainfall being heavy and the exposure favourable, they are densely clothed with vegetation. Many of the spurs abut steeply upon the Black sea, so that this littoral region is very rugged and not readily accessible. The seaward flanking ranges run up to 4,000ft. and more, and in many places form cliffs which overhang the coast some 2,000–3,000ft., while the main range gradually ascends to 10,000–12,000ft. as it advances east, the principal peaks being Fisht (8,040ft.), Oshten (9,210ft.), Shuguz (10,640ft.), and Psysh (12,425ft.). The main range is built up of hard crystalline rocks, and the subsidiary chains are composed of softer strata (Cretaceous and Tertiary) which are more easily disintegrated. The snowline is about 9,000ft. on the loftiest summits, and east of Oshten the crest of the main range is capped with perpetual snow and carries many hanging glaciers, while larger glaciers creep down the principal valleys. The few passes lie at relatively great altitudes, so that although the northern versants of the various ranges all have a gentle slope, communication between the Black sea and the valley of the Kubañ, and the low steppe country beyond, is not easy. The more important passes, proceeding from west to east are Pshekh (5,435ft.), and Shetlib (6,060ft.), Pseashka (6,880ft.), Sanchar (7,990ft.); between the last-named and Elbruz are the passes of Marukh (11,500ft.), Klukhor (9,450ft.) and Nakhar (9,615ft.).

BY COURTESY OF NEAR EAST RELIEF
NATIVE OF THE CAUCASUS

Owing to topographical and climatic conditions the southern exposure fosters a luxuriant and abundant vegetation. The most distinguishing feature of the flora is the predominance of arborescent growths; forests cover 56% of the area and are not only dense but laced together with climbing and twining plants. The commonest species of trees are such as grow in central Europe, viz., ash, fir, pine, beech, acacia, maple, birch, box, chestnut, laurel, holm-oak, poplar, elm, lime, yew, elder, willow, oak. The common box is especially prevalent, but the preponderating species are *Coniferae*, including the Caucasian species *Pinus halepensis and P. insignis*. The commonest firs are *Abies nordmannia* and *A. orientalis*. There are two native oaks, *Quercus ponticus* and *Q. sessiliflora*. A great variety of shrubs grow on these slopes of the western Caucasus, chiefly the following species, several of which are indigenous—*Rhododendron ponticum, Azalea pontica, Aristotelia maqui, Agave americana, Cephalaria tatarica, Cotoneaster pyracantha, Citrus aurantium, Diospyros ebenum, Ficus carica, Illicium anisatum, Ligustrum caucasicum, Punica granatum, Philadelphus coronarius, Pyrus salicifolia, Rhus cotinus* and six species of *Viburnum*. A great variety of aquatic plants thrive excellently. The following purely Caucasian species also grow on the coast—five species of spearwort, three of saxifrage, *Aster caucasica, Dioscorea caucasica, Echinops raddeanus, Hedera colchica, Helleborus caucasica* and *Peucedanum caucasicum*. Here too are found magnolia, azalea, camellia, begonia and paulownia. Among the cultivated trees and shrubs the most valuable are the vine, peach, pomegranate, fig, olive (up to 1,500ft. above sea-level), chestnut, apricot, apple, pear, plum, cherry, melon, tea (on the coast between Sukhum-Kaleh and Batum), maize (yielding the staple food of the inhabitants), wheat (up to 6,000ft.), potatoes, peas, currants, cotton, rice, colza and tobacco. After the Russian conquest half a million of the inhabitants of this region being Mohammedans, and refusing to submit to the yoke of Christian Russia, emigrated into Turkish territory, and the country where they had lived remained for the most part unoccupied until after the beginning of the 20th century. The coast-line is remarkably regular, there being no deep bays and few seaports. The best accommodation that these latter afford consists of more or less open roadsteads, *e.g.*, Novorossiisk, Gelenjik, Anapa, Sukhum-Kaleh, Poti and Batum. Along the coast are summer bathing resorts similar to those of the south-east coast of the Crimea. The largest are Anapa, Gelenjik and Gagry.

Middle Caucasus: (*a*) **Western Half.**—This sub-section, having a length of 200m., reaches from Mt. Elbruz to Kasbek and the Pass of Darial. It contains the loftiest peaks of the whole range, of which those above 15,000ft. are:—Elbruz (west peak) 18,465ft. and (east peak) 18,345ft., Jaikyl 17,780ft., Dykh-tau 17,050ft., Shkara 17,040ft., Koshtan-tau 16,875ft., Janga-tau 16,660ft. (west peak) and 16,525ft. (east peak), Kasbek 16,545ft., Mishirghi-tau 16,410ft. (west peak) and 16,350ft. (east peak), Adish or Katuyntau 16,295ft., Gestola 15,940ft., Tetnuld 15,920ft., Gimarai-Khokh 15,670ft., Ushba 15,410ft. (south-west peak) and 15,400ft. (north-east peak), Ullu-auz 15,350ft., Adai-Khokh 15,275ft., Tikhtengen 15,135ft., Tiutiun-tau 15,115ft.

The crest of the main range runs at an altitude exceeding 10,000ft., but is surpassed in elevation by the secondary range to the north, the Bokovoi Khrebet. These ranges are connected by more than half a dozen short transverse spurs enclosing as many cirques. Besides the Bokovoi Khrebet several other short subsidiary ranges branch off from the main range at acute angles, with high glens between them. Down all these glens glacier streams descend, until they find an opportunity to pierce through the flanking ranges, which they do in deep gorges, and then race down the northern slopes of the mountains to enter the Terek or the Kubañ, or down the southern versant to join the Rion or the Kura. Amongst all these high glens there is a remarkable absence of lakes and waterfalls; nor are there down in the lower valleys, as one would expect in a region so extensively glaciated, any sheets of water corresponding to the Swiss lakes. In this section of the Caucasus the loftiest peaks do not as a rule rise on the main range, but in many cases on the short spurs that link it with the Bokovoi Khrebet and other subsidiary ranges.

Glaciers.—The snow-line runs at 9,500 to 10,000ft. on the northern face and 1,000ft. higher on the southern face. There are over 900 glaciers in this section, and although they often rival those of the Alps in size, they do not descend generally to such low altitudes. The best known are the Bezingi or Ullu, between Dykh-tau and Janga-tau, 10½m. long, and descending to 6,535ft. above sea-level; Leksyr, situated south of Adyr-su-bashi, 7½m. long, and its end at 5,690ft., the lowest point to which any glacier descends on the south side of the range; Tseya or Zea, descending 6m. from the Adai-khokh to 6,730ft.; Karagom, from the same mountain, 9½m. long, and reaching down to 5,790ft., the lowest on the northern side; Dyevdorak or Devdorak, from Kasbek, 2½m. long, its end at 7,530ft.; Khaldeh or Geresho 4¼m. long, from Shkara and Janga-tau; Tuyber from Tetnuld, 6½m. long, and reaching down to 6,565ft.; Tsanner or Zanner, the same length, but stopping short 240ft. higher, likewise given off by Tetnuld; while between that peak, Adish and Gestola originates the Adish or Lardkhat glacier, 5m. long and terminating at 7,450ft. The total area covered by glaciers in the central Caucasus is estimated at 625 to 650sq.m., the longest being the Maliev on Kasbek, 36m. long; but according to M. Rossikov several of the largest glaciers are retreating, the Tseya at the rate of something like 40–45ft. per annum.

Passes.—It is in this section that the mountain system is narrowest, and here (apart from the "gate" at Derbent close beside the Caspian) are the principal north to south communications, between south Russia and Armenia and Asia Minor. These are the passes of Darial and Mamison. Over the former, which lies

immediately east of Kasbek, runs the Georgian military road (1811–64) from Vladikavkaz to Tiflis, cutting through the mountains by a beautiful gorge (8m. long), shut in by mountain walls nearly 6,000ft. high, and so narrow that there is only just room for the road and the river Terek side by side. The pass by which this road crosses the main range farther south is known as the Krestovaya Gora and lies 7,805ft. above sea-level. The Mamison pass, over which runs the Ossetic military road (made passable for vehicles in 1889) from the Terek (below Vladikavkaz) to Kutais in the valley of the Rion, skirting the eastern foot of the Adaikhokh, lies at an altitude of 9,270ft. and is situated a little south of the main range. Horses can traverse only the best of the other passes and only during a few weeks in summer. They range at altitudes of 9,000–12,500ft., and between the pass of Nakhar in the west and that of Mamison in the east there is not a pass below 10,000ft. The best known are Chiper (10,800–10,720ft.), Bassa (9,950ft.), Donguz-orun (10,490ft.), Becho (11,070ft.), Akh-su (12,465ft.), Bak (10,220ft.), Adyr-su (12,305ft.), Bezingi (10,090ft.), Shari-vizk (11,560ft.), Edena, Pasis-mta or Godivizk (11,270ft.), Shtulu-vizk (10,860ft.), Fytnargyn (11,130ft.), Bakh-fandak (9,570ft.), the two Karaul passes (11,680 and 11,270ft.) and Gurdzi-vizk (10,970ft.). The most frequented pass in Svanetia is that of Latpari (9,260ft.), situated in the first of the southern subsidiary ranges mentioned above, and thus connecting the valleys of the Ingur and the Tskhenis-Tskhali.

Flora.—In this section of the range again the southern slopes are clothed with vegetation of remarkable luxuriance and richness, more especially in the region of Svanetia (42°–43° E.). Here again the plants are bigger and the blossoms more abundant than in the Alps, forests of *Coniferae* predominate, and gigantic male ferns (*Aspidium filix-mas*), *Paris incompleta* (a member of the Trilliaceae), *Usnea* or tree-moss, box, holly (*Ilex aquifolium*), *Lilium monadelphum* and many of the herbaceous plants which flower in English gardens, grow here to an extraordinary size—monkshoods, *Cephalaria*, *Mulgedia* and groundsels. Other species are *Campanula*, *Pyrethrum*, aconite, *Cephaëlis*, speedwell, *Alchemilla sericea*, *Centaurea macrocephala*, *Primula grandis* and a species of primrose. Flowers of great beauty and abundance blossom up to 13,000ft. on the northern slope and on the southern slope ascend 2,000ft. higher. Walnuts grow up to an altitude of 5,400ft., the vine and mulberry to 3,250ft., the lime and ash to 4,000ft. The forests extend to the upper end of the limestone gorges. Above that the crystalline schists are bare of tree vegetation. The upper limit of arborescent vegetation is 7,000–7,500ft., of shrubs, *e.g.*, rhododendrons, 8,500ft., and of pasture-lands up to 9,000ft. The principal cultivated varieties of plants in this section are wheat, rye, oats, barley, beans, millet and tobacco.

Middle Caucasus: (*b*) **Eastern Part.**—In this sub-section, which stretches from Kasbek and the Darial gorge to the Babadagh in 48° 25′ E., a distance of 230m., the Caucasus attains its greatest breadth. For the whole distance the main range keeps an average elevation of 10,000ft., though the peaks are 2,000 to nearly 5,000ft. higher, the altitudes increasing towards the east. The glaciers decrease in the same proportion. Here the principal peaks, again found chiefly on the spurs and subsidiary ranges, are the Tsmiakom-khokh (13,570ft.), Shan-tau (14,530ft.), Kidenais-magali (13,840ft.), Zilga-khokh (12,645ft.), Zikari (12,565ft.), Choukhi (12,110ft.), Julti-dagh (12,430ft.), Alakhun-dagh (12,690ft.) and Maghi-dagh (12,445ft.). On the main range stand Borbalo (10,175ft.), Great Shavi-kildeh (12,325ft.), Murov (11,110ft.), Ansal (11,740ft.), Ginor-roso (11,120ft.), while farther east come Trfan-dagh (13,765ft.) and Bazardyuz or Kichen (14,727ft.). In the same direction, but again outside the main range, lie Shah-dagh (13,955ft.), Shalbuz (13,675ft.) and Malkamud (12,750ft.).

The most noteworthy feature of this section is the broad *highland region of Daghestan*, which flanks the main range on the north and sinks down to the Caspian sea (east), and to the valley of the Terek (north). On the north-west this rugged highland region is well defined by the transverse ridge of Andi, which to the east of Kasbek strikes off from the Caucasus range almost at right angles. The rest of the Daghestan region consists of a series of roughly parallel folds, of Jurassic age, ranging in altitudes from 7,500 up to 12,500ft., separated by deep river glens which cut it up into a number of arid, treeless plateaus. The most prominent of these tablelands is Bash-lam, which stretches east and west between the Chanti Argun and the Andian Koisu. Upon it rise the conspicuous peaks of Tebulos-mta (14,775ft.), Tugo-mta (13,795ft.), Komitotavi or Kachu (14,010ft.), Donos-mta (13,560ft.), Diklos-mta (13,740ft.), Kvavlos-mta or Kolos-mta (13,080ft.), Motshekh-tsferi (13,140ft.) and Galavanas-tsferi (13,260ft.). Farther east is the Bogos tableland, stretching from south-south-west to east-north-east between the Andian Koisu and the Avarian Koisu and rising to over 13,400ft. in several peaks, *e.g.*, Antshovala (13,440ft.), Botshokh-meër (13,515ft.), Kosara-ku (13,420ft.) and Addala-shuogchol-meër (13,580ft.); and the Dyulty tableland reaching 12,400ft. between the Kara Koisu and the Kazikumukh Koisu. Névé and glaciers occur on some of these peaks, particularly on the slopes of Diklos-mta, where the glaciers descend to 7,700ft. (north) and to 8,350ft. (south). Here the passes are lower than those between Elbruz and Kasbek, though at appreciable heights, fully equal to those that lead up from the Black sea to the valley of the Kubañ in the western section of the range. The best known are the Krestovaya Gora (7,805ft.) on the Georgian military road south of Darial; Kodor (9,300ft.) and Satskheni, and Gudur (10,120ft.) and Salavat (9,280ft.), carrying the Akhty military road.

The *flora* of this section bears a general resemblance to that farther west. Ample details will be found in Dr. G. Radde's (1831–1903) monographs on Daghestan.

Eastern Caucasus.—This section of the Caucasus gradually dies away east of Baba-dagh (11,930ft.) towards the Caspian, terminating finally in the peninsula of Apsheron. It is, however, continued under the waters of the Caspian and reappears on its eastern side in the Kopet-dagh, which skirts the north-eastern frontier of Persia. In this section of the Caucasus no peak exceeds 9,000ft. in altitude and the crest of the main range retains no snow. The most frequented pass is Alty-agach (4,355ft.).

Between the northern and the southern sides of the range there is a great difference in climate, productions and scenery. In the south-western slopes and valleys where a heavy rainfall is combined with a warm temperature, magnificent forests clothe the mountain-sides and reach the waters of the Black sea. There the littoral from, say, Sukhum-kaleh to Batum, and the inland parts of the basin of the Rion, will bear comparison with any of the provinces of Italy in richness and variety of products. But farther inland, east of Tiflis, a great change becomes noticeable on the other side of the transverse ridge of the Suram or Meskes mountains. Arid upland plains and parched hillsides take the place of the rich verdure and luxuriant arborescent growth of Imeretia, Svanetia and Mingrelia, the districts which occupy the valleys of the Ingur and Rion and the tributaries of the latter. A very similar change likewise becomes noticeable in the higher regions of the Caucasus mountains north of the pass of Mamison. The valleys of the Rion and Ardon and of others that flow in the same direction, are almost wholly destitute of trees, but where the bare rock does not prevail, the mountain slopes are carpeted with grass. "Treeless valleys, bold rocks, slopes of forbidding steepness (even to eyes accustomed to those of the Alps), and stone-built villages, scarcely distinguishable from the neighbouring crags" (Freshfield) Austere and unattractive though those valleys are, the same epithets cannot be applied to the deep gorges by which in most cases the streams make their escape through the northern subsidiary range. These defiles are declared to be superior in grandeur to anything of the kind in the Alps. That of Darial (the Terek) is fairly well known, but those of the Cherek and the Urukh, farther west, are stated to be still more magnificent. Not only do the snow-clad ranges and the ice-panoplied peaks surpass the loftiest summits of the Alps in altitude; they also in many cases excel them in boldness and picturesqueness of outline, and equal the most difficult of them in steepness and relative inaccessibility.

Hydrography.—Nearly all the larger rivers of Caucasia have their sources in the central parts of the Caucasus range. The torrential streams of Mdzimta, Pzou, Bzyb and Kodor drain the

country west of Elbruz. The Ingur, Tskhenis-Tskhali, Rion and its tributaries, *e.g.*, the Kvirila, are longer but also in part torrential; they drain the great glacier region between Elbruz and Kasbek. The Rion is the *Phasis* of the ancients and flows through the classic land of Colchis. The Lyakhva and Aragva, tributaries of the Kura, carry off the waters of the main range south of Kasbek, and other tributaries, such as the Yora and the Alazan, collect the surplus drainage of the main Caucasus range farther east. The other large river of this region, the Aras, has its sources, not in the Caucasus range, but on the Armenian highlands a long way south-west of Ararat. The rivers which go down northwards from the central Caucasus have longer courses than those on the south. The most important of these are the Kubañ and the Terek; most of the streams which have their sources among the central glaciers draining into the latter, *e.g.*, the Malka, Baksan, Chegem, Cherek, Urukh, Ardon. The Kuma, which alone pursues an independent course through the steppes, farther north than the Terek, has its sources, not in the main ranges of the Caucasus, but in a group of mountains near Pyatigorsk. Its waters become absorbed in the sands of the desert steppes before they reach the Caspian. Of the streams that carve into chequers the elevated plateau of Daghestan, four, known by the common name of the Koisu, unite to form the Sulak. The only other stream deserving of mention in this province is the Samur. Both rivers discharge their waters into the Caspian, as also does the Zumgail, a small stream which drains the eastern extremity of the Caucasus range.

Volcanic Evidences.—Ancient but now extinct volcanic centres occur frequently at the intersections of the main range with the transverse ranges; of these the most noteworthy are Elbruz and Kasbek. The town of Shemakha near the eastern end of the system was the scene of volcanic outbreaks as late as 1859, 1872 and 1902; while in the adjacent peninsula of Apsheron mud volcanoes exist in large numbers. All along the northern foot of the system hot mineral springs gush out at various places, such as Pyatigorsk, Zhelesnovodsk, Essentuki and Kislovodsk; and the series is continued along the north-eastern foot of the highlands of Daghestan, *e.g.*, Isti-su, Eskiendery, Akhta. Also similar evidences of volcanic activity characterize the northern border of the Armenian highlands on the southern side of the Rion-Kura depression, in the mountains of Ararat, Alagöz, Akmangan, Samsar, Godoreby, Great and Little Abull, and in the mineral springs of Borzhom, Abbas-tuman, Sleptzov, Mikhailovsk and Tiflis.

Geology.—The structure of the Caucasus is comparatively simple, and in the form of a fan. In the centre are crystalline rocks which disappear towards the east. Beneath them, on both sides, plunge the strongly folded Palaeozoic and Jurassic schists. On the north the folded beds are followed by a zone of Jurassic and Cretaceous beds which rapidly assume a gentle inclination towards the plain. On the south the corresponding zone is affected by numerous secondary folds which involve Upper Miocene deposits. In the east, the structure is somewhat modified. The crystalline band is lost. The northern Mesozoic zone is very much broader, and is thrown into simple folds like those of the Jura mountains. The Mesozoic zone is absent in the south, and the Palaeozoic zone sinks abruptly in a series of faulted steps to the plain of the Kura, beneath which no doubt the continuation of the Mesozoic zone is concealed.

The geological sequence begins with the granite and schists of the central zone, which extend from Fisht (west) to some distance beyond Kasbek (east). Then follow the Palaeozoic schists and slates. Fossils are extremely rare in these beds; *Buthotrephis* has long been known, and traces of *Calamites* and ferns, and in the west fossils which appear to indicate a Devonian age. Upon the Palaeozoic rest Mesozoic deposits (Lias to Upper Cretaceous). Different views exist as to the position of unconformities, but important ones occur at the base of the Tithonian (Upper Jurassic) and at the base of the Trias. In general the Upper Jurassic beds are much more calcareous on the north than they are on the south. The Mesozoic are followed by Tertiary deposits, which on the north are nearly horizontal but on the south are in part included in the folds—the Eocene and Miocene being folded, while later beds, though sometimes elevated, may not be affected by the folding. The final folding of the chain, proceeding from north-east, undoubtedly occurred at the end of the Miocene period. Folding also occurred probably during the Permian and again during the Upper Jurassic (direction south-west). Also the difference in character of the Jurassic beds on the two sides of the chain appears to indicate that a ridge existed in that period. The last phase in the history of the Caucasus was the growth of the great volcanoes of Elbruz and Kasbek, which stand upon the old rocks of the central zone, and by the outflow of sheets of lava upon the sides of the chain. The cones are composed largely of acid andesites, but many of the lavas are augite andesites and basalts. There seem to have been two periods of eruption, and as some of the lavas have flowed over Quaternary gravels, the latest outbursts must have been of very recent date.

Near the northern foot of the Caucasus, especially near the hot mineral springs of Pyatigorsk, a group of igneous rocks rises above the plain. They are laccolites of trachytic rock, and raised the Tertiary beds above them in the form of blisters. Subsequent denudation has removed the sedimentary covering and exposed the igneous core. Petroleum occurs in the Tertiary beds at both ends of the chain.

Freshfield, *Exploration of the Caucasus* (2nd ed., 1902, 2 vols.); H. Abich, *Aus Kaukasischen Ländern* (2 vols., 1896); C. von Hahn, *Kaukasische Reisen und Studien* (1896) and *Bilder aus dem Kaukasus* (1900); G. Merzbacher, *Aus den Hochregionen des Kaukasus* (2 vols., 1901); J. Mourier, *L'Art au Caucase* (new ed., 1912); E. A. Martel, *La Côte d'Azur russe* (1909); S. Graham, *A Vagabond in the Caucasus* (1911); A. Herbert, *Casuals in the Caucasus* (1912); M. Rikli, *Natur und Kulturbilden der Eiszeit im Kaukasus* (1914); M. Varandian, *La conflit arméno-géorgien et la guerre du Caucase* (1919); A. Dirr, *Caucasian folk-tales* (1925). The geology of the Caucasus is dealt with in E. Fournier, *Description géologique du Caucase central* (1896); F. Löwinson-Lessing, *Guide des Excursions du VIIe Congrès géol. internat.* (1897); and F. Oswald, *Notes on the Geological Map of the Caucasus* (1914). *A travers le Caucase* (1905) by E. Levier is especially valuable for botany and N. Y. Dinnik writes on the fauna in *Bull. Soc. Impériale des Naturalistes de Moscou* (1901). Much valuable information about the Caucasus is preserved in *Izvestia* and *Zapiski* of the Russian and Caucasian geographical societies. V. Dingelstedt has a number of papers on this region in the *Scottish Geographical Magazine* (1889–1904). A useful geological map is by F. Oswald (1914), scale of 1:1,000,000; and the Russian general staff have a good map on the scale of 1:210,000. (J. I. P.)

HISTORY

To the ancient Greeks Caucasia, and the mighty range which dominates it, were a region of mystery and romance. It was there that they placed the scene of the sufferings of Prometheus (*vide* Aeschylus, *Prometheus Vinctus*), and there, in the land of Colchis, which corresponds to the valley of the Rion, that they sent the Argonauts to fetch the golden fleece. Outside the domain of myth, the earliest connection of the Greeks with Caucasia would appear to have been through the maritime colonies, such as Dioscurias, which the Milesians founded on the Black sea coast in the 7th century B.C. For more than two thousand years the most powerful state in Caucasia was that of Georgia (*q.v.*). The southern portion of Transcaucasia fell during the 1st century B.C. under the sway of Armenia, and with that country passed under the dominion of Rome, and so eventually of the Eastern empire. During the 3rd century A.D. Georgia and Armenia were invaded and in great part occupied by the Khazars, and then for more than a thousand years the mountain fastnesses of this borderland between Europe and Asia were the refuge, or the resting-place, of successive waves of migration. The Huns and the Avars appeared in the 6th century, and the Mongols in the 13th. In the 10th century bands of Varangians or Russified Scandinavians sailed out of the Volga and coasted along the Caspian until they had doubled the Apsheron peninsula, when they landed and captured Barda, the chief town of Caucasian Albania.

But, apart from Georgia, historical interest in Caucasia centres in the long and persistent attempts which the Russians made to conquer it, and the heroic, though unavailing, resistance offered by the mountain races, more especially the Circassian and Lesghian tribes. Russian aggression began early in the 18th cen-

tury, when Peter the Great, establishing his base at Astrakhan on the Volga, and using the Caspian for bringing up supplies and munitions of war, captured Derbent from the Persians in 1722, and Baku in 1723. But these conquests, with others made at the expense of Persia, were restored to the latter power after Peter's death, a dozen years later. At that period the Georgians were divided into various petty principalities, the chief of which were Imeretia and Georgia (Kharthlia), owing at times a more or less shadowy allegiance to the Ottoman sultan. In 1770, when at war with Turkey, the Russians crossed over the Caucasus and assisted the Imeretians to resist the Turks, and from the time of the ensuing peace of Kuchuk-kainarji the Georgian principalities looked to Russia as their protector against the Turks. In 1783 George XIII., prince of Georgia and Mingrelia, formally put himself under the suzerainty of Russia, and after his death Georgia was converted (1801) into a Russian province. The same fate overtook Imeretia nine years later. Meanwhile the Russians had also subdued the Ossetes (1802) and the Lesghian tribes (1803) of the middle Caucasus. By the peace of Gulistan in 1813 Persia ceded to Russia several districts in Eastern Caucasia, from Lenkoran northwards to Derbent. Nevertheless the mountain tribes were still independent, and their subjugation cost Russia a sustained effort of thirty years. At first the Russians were able to continue their policy of conquest and annexation without serious check. After acquiring the northern edge of the Armenian plateau, partly from Persia in 1828 and partly from Turkey in 1829, Russia in 1832 crushed a rising in Daghestan. The next seven years were occupied with the subjugation of the Abkhasians along the Black sea coast, and of other Circassian tribes in the west. Meanwhile Shamyl, a chief and religious leader of the Lesghians, had roused the Lesghian tribes farther east. His resistance was finally broken after 20 years of warfare by Prince Baryatinsky, who succeeded in capturing Shamyl's stronghold of Weden, and then in surrounding and capturing (1859) that chieftain himself on the inaccessible rocky platform of Gunib in the heart of Daghestan. But it was not until 1864 that the Russians finally stifled all opposition. Then followed a wholesale emigration of the Circassians, who sought an asylum in Turkish territory, leaving their native region almost uninhabited and desolate. During the Russo-Turkish War of 1877–78 the self-exiled Circassians and other Caucasian mountaineers, supported by a force of 14,000 Turks, made a determined attempt to wrest their native glens from the power of Russia; but, after suffering a severe defeat at the hands of General Alkhazov, the Turks withdrew, and were accompanied by some 30,000 Abkhasians, who settled in Asia Minor. A few months later the Lesghians in Daghestan, who had risen in revolt, were defeated and their country once more reduced to obedience. By the peace of Adrianople, Russia still further enlarged her Transcaucasian territories by the acquisition of the districts of Kars, Batum and Ardahan. After a peaceful period of a quarter of a century the Armenian subjects of Russia in Transcaucasia were filled with bitterness and discontent by the confiscation of the properties of their national (Gregorian) Church by the Russian treasury. Nor were their feelings more than half allayed by the arrangement which made their ecclesiastics salaried officers of the Russian state. This ferment of unrest, which was provoked in the years 1903–04, was exacerbated by the renewed outbreak of the century-long racial feud between the Tatars and the Armenians, at Baku and other places. Nearly the whole of the region between the Caucasus and the Perso-Turkish frontier on the south, from the Caspian sea on the one side to the Black sea on the other, was embroiled in a civil war of the most sanguinary and ruthless character, the inveterate racial animosities of the combatants being in both cases inflamed by religious fanaticism. An end was put to these disorders only by the mutual agreement of the two contestants in Sept. 1905.

The Revolution of 1905 in Russia aroused the desire for self-government that has never long been dormant in the Caucasus. The agrarian policy of the Tsarist Government added fuel to the fire of discontent, and the refusal to recognize their individual national languages was a further source of grievance to Armenians, Tatars and Georgians alike. Nevertheless the Russian Government ruthlessly pursued its repressive policy. On the outbreak of the World War in 1914, when they had learnt that Russia was the ally of France and Great Britain, the Caucasian nationalities eagerly responded to the call to arms. But even this action had no effect upon the Russian Government, and the governship of General Yudenitch was specially noteworthy for its severity. Hence the February Revolution of 1917 was hailed with joy throughout the Caucasus when the individual nationalities attempted to establish a Federal republic that should be governed by a Transcaucasian diet. But the failure of Kerensky's administration and the triumph of Bolshevism spelt failure for the Caucasian Republic also. The component states made a brief attempt to preserve their independence of Moscow under mildly socialistic forms of government, but the military strength of the Soviet soon overcame their resistance. First one and then another was overrun and conquered, and Soviet republics set up under the guidance of Moscow. Despite the maintenance by the Moscow Government of these republics in the Caucasus, the desire amongst some of the population for complete independence of the U.S.S.R. has not been extinguished.

CAUCASUS, CAMPAIGN IN THE. Though both Russian and Turk spoke of a "Caucasus front" and gave to their armies engaged on this front the designation "Caucasian" in World War I, the operations actually took place at a considerable distance from the Caucasus in the region covered by the historical term Armenia, a bleak, almost undeveloped area. In 1914, on the Russian side, railway communication ended at Sarikamis, about 40 mi. S.W. of Kars and 15 mi. from the frontier; on the Turkish side, 600 mi. of indifferent roads and tracks separated their armies operating in the Erzerum area from the railhead at Ankara.

The Turkish Plan.—The 3rd Turkish army had been assembling during Sept. and Oct. 1914 in the neighbourhood of Erzerum. It consisted of three army corps with the fighting strength of about 100,000 men. The plan evolved by Enver Pasha was a wide enveloping movement with Kars as the objective. This plan wholly ignored the absence of communications and the climatic conditions. The Russian attitude was, at the outset, purely defensive; two of the three regular corps, stationed in the Caucasus in peace, had been sent to the Austro-German front. Yet the Russians made the first advance, moving across the frontier on the road to Erzerum.

Enver arrived from Constantinople and assumed personal command of the 3rd army. He insisted, against the views of his German advisers, on putting into execution the ambitious plan he had conceived. Yet such fortitude and endurance did the poorly equipped and ill-fed Turkish troops display that they almost achieved the impossible. While the main Russian body was engaged with the 11th corps, the 9th corps appeared, in the last days of Dec. 1914, on the heights above Sarikamis, and the 10th corps on its left approached Kars. The Russian commander's nerve failed him at the crisis; and the situation was saved only by his chief of the staff, Gen. N. N. Yudenich. He collected forces for a counterattack, which resulted in the practical annihilation of the two Turkish turning corps, worn out and disorganized by their approach march; the 11th corps was then in its turn driven back. The losses of the Turkish 3rd army were about 85%. Enver at once handed over the command and returned to Constantinople.

During the whole of 1915 the fighting on the Caucasus front was of minor importance only, the main preoccupation lying elsewhere. The shattered 3rd army was gradually reconstituted under Mahmud Kiamil, and the Russians raised fresh units. But neither side was yet in shape for a serious offensive. In Sept. 1915 Grand Duke Nicholas took over command of the Caucasus front, an event which markedly enlarged the Russian effort in this theatre.

The Fall of Erzerum.—Once again an offensive on a large scale was made in the depth of winter. The grand duke wished to anticipate the arrival of Turkish reinforcements released by the British evacuation of Gallipoli. This enterprise was completely successful. The Russian capture of Erzerum (Feb. 16, 1916) was one of the finest feats of arms of World War I. The next Russian objective was Trebizond; its capture in April considerably simplified the supply problem. Meanwhile, the Turkish high command

had decided on a counterstroke. It ordered the assembly of a new army, the 2nd, under Izzet Pasha, in the Mush-Kharput region, to attack the Russian flank and rear and recapture Erzerum. The plan was sound enough, but the assembly, begun in April, was not complete in July. The grand duke became aware of the Turkish intentions and anticipated their attack by a heavy blow at the 3rd army, and broke it. The Russians occupied Erzincan in July. The counterstroke of the 2nd army took place in August, giving the Russians time to transfer troops from their right wing to meet it. After some heavy fighting the 2nd army's effort was definitely held. It had gained little ground at a considerable sacrifice in men.

During the winter of 1916–17 no movements took place. The Turkish 2nd and 3rd armies (Mustafa Kemal and Vahib Pasha respectively), now combined under Izzet Pasha, suffered terrible privations. Nor were the Russians much better off.

Attempted Russo-British Co-operation.—In Dec. 1916 the British army in Mesopotamia, under Gen. Sir Frederick Maude, began the attacks on the Turks at Kut, which were to lead to the capture of Baghdad in March. It was agreed that the cavalry corps of Baratov from Persia and of Chernozubov from between lakes Urmia and Van should advance on Mosul and thus, in co-operation with Maude, end the Mesopotamian campaign. The grand duke adopted the plan wholeheartedly, and the Turks would not have been able to resist effectively. But weather conditions and the difficulty of organizing a line of supply through the mountains of the Persian border caused delay; then the Russian revolution broke out.

Collapse of the Russian Army.—Throughout the summer the Russian army lay inactive, gradually disintegrating. Yudenich, who had succeeded the grand duke, gave up the command in August and was succeeded by Przhevalsky. But the end was near. In December an armistice was concluded on the Caucasus front, and after the peace of Brest-Litovsk (March 3, 1918), the Turks occupied Batum on April 14 and Kars on the 26th. But the Turkish control of Transcaucasia was short-lived, for General Allenby's crushing victory in Palestine spelled the loss of the war for the Turks. (A. P. W.; X.)

CAUCHON, PIERRE, French ecclesiastic, was born near Reims and became bishop of Beauvais in 1420, after having been a leading master of the University of Paris and a civil servant to the Burgundian government. As a councillor to the duke of Bedford, he presided over the trial of Joan of Arc at Rouen, which constitutes his chief title to fame. He took care to conduct the trial according to inquisitorial procedure and to obtain from the Maid a confession which would save her life.

In 1432 he became bishop of Lisieux. He took part in the Council at Basel in 1435. Cauchon died in 1442 and was subsequently excommunicated by Calixtus III.

See A Sarrazin, *Pierre Cauchon* (Paris, 1901); and works dealing with the trial of Joan of Arc (*q.v.*).

CAUCHY, AUGUSTIN LOUIS, Baron (1789–1857), French mathematician, was born in Paris, on Aug. 21, 1789, and died at Sceaux (Seine) on May 23, 1857. He studied at the École Polytechnique and the École des Ponts et Chaussées, and practised for some time as an engineer.

His health failed in 1813, and his father's friends, Lagrange and Laplace, persuaded him to devote himself entirely to mathematics. From 1816 onward he held three professorships in Paris, which he lost at the revolution of 1830, on declining to swear allegiance to Louis Philippe. A chair of mathematical physics was created for him at the University of Turin. He spent some time travelling with the duke of Bordeaux, grandson of Charles X, and in 1838 returned to France, resuming his chair at the École Polytechnique. Although acting only from the highest motives, Cauchy made himself objectionable to his colleagues by a self-righteous obstinacy and an aggressive religious bigotry.

The genius of Cauchy was promised in his simple solution of the problem of Apollonius (*i.e.*, to describe a circle touching three given circles) which he discovered in 1805, and in his generalization of Euler's theorem on polyhedra in 1811. More important is his memoir on wave propagation which obtained the *grand prix* of the Institut in 1816. His greatest contributions to mathematical science are characterized by the clear and rigorous methods which he introduced and are mainly embodied in his three great treatises, *Cours d'analyse de l'École Polytechnique* (1821); *Le Calcul infinitésimal* (1823); *Leçons sur les applications du calcul infinitésimal à la géométrie* (1826–28). He clarified the principles of the calculus by developing them with the aid of limits and continuity and was the first to prove Taylor's theorem rigorously, establishing his well-known form of the remainder. Thus the first phase of modern rigour, giving a satisfactory basis for the calculus, originated in Cauchy's lectures and researches of the 1820s in analysis. To the same period belongs his development of his (the first) version of the theory of functions of a complex variable, today indispensable in applied mathematics from physics to aeronautics. With equal originality, he made substantial contributions to the theory of numbers where, however, he went astray on Fermat's last theorem. He was one of the originators of the theory of permutation groups. In astronomy, he gave a shorter account than Leverrier's of the motion of Pallas. In mechanics, he made many researches, substituting the notion of the continuity of geometrical displacements for the principle of the continuity of matter. In optics, he developed the wave theory, and his name is associated with the simple dispersion formula. In elasticity, he originated the theory of stress, and his results are nearly as valuable as those of S. D. Poisson. His collected works, *Œuvres complètes d'Augustin Cauchy,* have been published in 27 volumes.

See C. A. Valson, *Le Baron Augustin Cauchy: sa vie et ses travaux* (1868).

CAUCUS, a political term used in the U.S. of a special form of party meeting, and in Great Britain of a system of party organization. The word originated in Boston, Mass., in the early part of the 18th century, when it was used as the name of a political club, the Caucus or Caucas club. There public matters were discussed and arrangements made for local elections and the choosing of candidates for offices. A contemporary reference to the club occurs in the diary of John Adams in 1763; but William Gordon (*History of the Independence of the United States of America* [1788]) speaks of the Caucus as having been in existence about 50 years before the time of writing (1774) and describes the methods used for securing the election of the candidates. The derivation of the word has been much disputed. The most plausible origin is an Algonquin word, *kaw-kaw-was,* meaning to talk, Indian words and names having been popular in America as titles for societies and clubs (*cf.* "Tammany"). In the United States "caucus" is used strictly of a meeting either of party managers or of duty voters, as for instance a "nominating caucus," for nominating candidates for office or for selecting delegates for a nominating convention. The caucus of the party in congress nominated the candidates for the offices of president and vice-president from 1800 till 1824, when the convention system was adopted. At the same time, the candidates for governor and lieutenant governor were nominated by the party members of the state legislatures in what was known as the legislative nominating caucus. Occasionally districts unrepresented in the legislature sent delegates to sit in with the members of the legislature when these nominations were made, and this was termed the mixed legislative nominating caucus. (*See* Primaries.)

The word is used in the United States to denote meetings of the members of a party in congress or in a legislature or a city council, to determine matters of party policy on proposed legislation or legislative offices. "Caucus" first came into use in Great Britain in 1878 in connection with the organization of the Liberal Association of Birmingham by Joseph Chamberlain and F. Schnadhorst on strict disciplinary lines, more particularly with a view to election management and the control of voters, which became the model for other Liberal associations throughout the country. It was to this supposed imitation of the U.S. political "machine" that Lord Beaconsfield gave the name "caucus," and the name came to be used, not in the U.S. sense of a meeting, but of a closely disciplined system of party organization, chiefly as a stock term of abuse applied by politicians of one party to the controlling

organization of its opponents.

CAUDINE FORKS, the *furculae Caudinae*, narrow passes in the mountains near Caudium in Samnium (possibly near Forchia) where the Samnites defeated the Romans in 321 B.C. *See* ROME: *Ancient History;* and E. T. Salmon in *J. Rom. Studies*, p. 12 ff. (1929).

CAUL, a close-fitting woman's cap, especially one made of network worn in the 16th and 17th centuries; hence, the serous membranous covering to the heart, brain or the intestines, and particularly, a portion of the amnion, or bag of waters, which is sometimes found remaining round the head of a child after birth. To this, called in Scotland "sely how," holy or lucky hood, many superstitions have been attached; it was looked on as a sign of good luck, and when preserved, was kept as a protection against drowning.

CAULAINCOURT, ARMAND AUGUSTIN LOUIS, MARQUIS DE (1773–1827), later DUKE OF VICENZA, was born on Dec. 9, 1773. His father was the friend of Josephine de Beauharnais and of Talleyrand and, after Thermidor, was able to help his son who had, as a noble, been deprived of his captaincy by the Revolution and was a cavalry sergeant in 1794. J. B. A. Aubert-Dubayet took him to Constantinople in 1796–97. Jean Bernadotte gave him a regiment in 1799, which he led at Hohenlinden. He was a good soldier, but Talleyrand chose him for the mission in 1801 to St. Petersburg, where he made a lasting impression on Alexander I. On return in 1802 he was made aide-de-camp to Napoleon. A mission against royalist agents in 1804 involved him in the arrest of the duc d'Enghien, but he always resented the charge that he had been an accomplice in the crime. Having been grand equerry in the great campaigns, he went as ambassador to Russia in Nov. 1807 and struggled to maintain the alliance. He was made duke of Vicenza in June 1808. Recalled almost in disgrace in 1811, he made, at Wilno (Vilnius) in 1812, a memorable protest against the invasion, when Napoleon called him a "Russian." Yet he was Napoleon's sole companion in the sledge journey from Smorgoni in December. In 1813 he signed the armistice of Pläswitz in June, was plenipotentiary at Prague in August and replaced H. B. Maret as minister of foreign affairs in November. He was Napoleon's "man of peace" and has been charged with betraying him in order to secure it. After the congress of Châtillon (February-March 1814) he returned to Napoleon, negotiated with the tsar, concluded the treaty of April 10, 1814, and was with Napoleon in the grim week which followed. Minister again in the Hundred Days, he was saved from proscription by Alexander's intervention. In retirement he tried to clear his name in the Enghien case. He died of cancer on Feb. 19, 1827.

See his *Mémoires*, ed. by J. Hanoteau, 3 vol. (Paris, 1933; Eng. trans., London, 1950). (I. D. E.)

CAULICULUS, in architecture, a form like a stalk, crowned with leaves, but which grow scrolls, leaves or other stalks; especially in the Corinthian capital, and in the branching scroll or *rinceau*.

CAULIFLOWER: *see* CABBAGE.

CAULONIA (Καυλωνια), an ancient Greek city in Italy, in the country of the Bruttii, on the east coast of Calabria. It was the southernmost Achaean colony, established perhaps in the first half of the 7th century B.C. as an outpost of Croton, with a founder from Achaea in the Peloponnese. It was always a small city, but its copious and beautiful archaic coinage (from the second half of the 6th century B.C.) shows its importance. It took the side of Athens in the Peloponnesian War. Destroyed by Dionysius of Syracuse in 389 B.C. but soon afterward restored, it was captured by Campanian troops during the invasion of Pyrrhus and stood a siege (209 B.C.) in Hannibal's interest. After this it declined, and Strabo speaks of it as deserted. Excavations have revealed remains of the fortifications with towers of the Hellenistic period. Near the shore scanty remains of a large Doric temple (first half of 5th century B.C.) were found, and a small temple must have stood near the lighthouse; copious architectural terra cottas, with elements derived from the Ionic order, are associated with both. The excavated houses belong to a late period. The tombs date from the 6th to the 3rd centuries B.C. but are poor.

See P. Orsi in *Monumenti dei Lincei*, xxiii (Rome, 1914), 685 *ff.*, and xxix (1924), 409 *ff.*

CAUSALITY or **CAUSATION.** The word "cause" is derived from the Latin *causa*, the standard translation of the Greek αἴτιον and αἰτία. By the time it came into English, in the 13th century, the word already had a wide range of uses, some of them highly sophisticated, since it was a key term in science, philosophy and the law.

Sense I: Human Agency.—Both *causa* and its Greek equivalents were used in legal contexts to refer to the voluntary action of an agent for which he could be held responsible. The responsible person is the person whose action could have been otherwise and but for whose action the event under investigation would not have occurred. One can already detect here the idea of the point of application of a remedy, an idea which, as we shall see, is an important element in later uses.

Divorced from its association with the law courts, the word "cause" is used for any action which an agent performs in order to bring about an event or state of affairs (the effect), whether in nature or in another agent. Thus a man can cause a statue to be unveiled by pressing a button or cause another man to do something by offering him a bribe. In this sense (sense I), to cause an event to occur is to perform an action with the expectation and intention that the event will follow. The words "produce" and "bring about" are synonyms of "cause" and can be used either of the agent or of his action. We also have a vast number of more specialized verbs such as "hit," "kick," "lift" and "move" which may be said to express causal ideas.

When one man causes another to do something, the second man is, under some circumstances, said to act, not "of his own free will," but "under compulsion" or "under constraint." To have power over someone is to be able to constrain, compel or oblige him to do something. We shall see that the idea of compelling, like that of producing, plays a part in later senses of "cause."

In ordinary life we are often concerned to produce, prevent or counteract events and states of affairs, but our actions are limited to the movements of our own bodies. I can move my own foot; I cannot, in the same sense, move a stone; but I can cause a stone to move by kicking it. To bring about any change in natural objects, it is necessary for us to know what action that we can perform will be followed by the desired change. Thus I cannot, of my own volition, heat water; but I can put a kettle on the fire, and I know that, if I do this in suitable circumstances, the water will be heated. It is often the case that the same change can be brought about by any of a number of alternative actions. Thus I can light a room either by pressing a switch or by drawing back the curtains or by striking a match. Each of these actions is called a "sufficient condition" of producing light; and since, in practice, it is usually required to know only that an action will be *sufficient*, not that it is *necessary*, to produce the effect, the word "cause" usually means sufficient condition. It is important to notice that, when we use "cause" in this way, the effect must be very broadly conceived. The sort of light produced by pressing a switch is very different from that produced by striking a match. The more narrowly the effect is specified the fewer will be the possible alternative sufficient conditions. Beheading, shooting through the heart and administering a dose of arsenic are all ways of causing death; but if the condition of the corpse is specified more narrowly than by the word "dead," a number of these possible causes will be excluded.

A cause, in this sense, must clearly be prior in time to its effect. It need not be contiguous in space and time; but since we know from our everyday experience that the transmission of movement from one body to another only occurs when the bodies are in contact, common sense always assumes that cause and effect are linked by a continuous substance. By igniting one end of a fuse I can cause an explosion to occur several minutes later and several yards away; but only if the fuse is unbroken.

Sense II: Causes in Nature.—By a natural transition the word "cause" is also used (sense II) for a natural event that stands in the same relation to some other event or state of affairs as the action stood in sense I. Thus the explosion that I caused

(sense I) by lighting the fuse could have been caused (sense II) by some sparks from a locomotive. For a reason to be given later, the ideas of "producing" and "compelling" which belong naturally to "cause" in sense I were retained for "cause" in sense II. A cause (sense II) was thought to be, not merely the sufficient condition of its effect, but something which had the power to produce it.

A great part of our early education consists in the discovery of causes in these two senses. Thus, in order to achieve our most elementary aims, it is necessary for us to know that fire burns, that food nourishes and that bodily injury causes pain. The idea of cause has its roots in purposive activity and is employed in the first instance when we are concerned to produce or to prevent something. To discover the cause of something is to discover what has to be altered by our own activity in order to produce or to prevent that thing; but once the word "cause" comes to be applied to natural events, the notion of altering the course of events tends to be dropped. "Cause" is then used in a nonpractical, purely diagnostic way in cases where we have no interest in altering events or power to alter them. Thus we can speak of the cause of an eclipse or of an earthquake. The connecting link between the practical and the purely diagnostic uses is the idea of "sufficient condition." To discover the cause of an event is to discover something among its temporal antecedents such that, if it had not been present, the event would not have occurred.

Cause in the Practical Sciences.—The concept of cause is widely employed in the practical sciences, such as medicine and engineering. For in these sciences we are largely interested either in bringing about a certain state of affairs (*e.g.*, building a bridge) or in locating the sufficient condition of a state of affairs with a view to its removal (*e.g.*, discovering the cause of a disease or of the breakdown of a machine). The procedure of a practical scientist differs from that of an ordinary intelligent man only in that he needs to be more careful and accurate in his diagnosis of causes and in that he is assisted in his diagnosis by being able to draw on a large fund of theoretical science (*e.g.*, physiology or mechanics).

From this it has been concluded that all science is the search for causes. This conception has been popular with philosophers such as Francis Bacon and J. S. Mill, who regarded science primarily as a means of acquiring power over nature. But to conclude that the statements of theoretical science must be fundamentally causal in form is to make the error of introducing into theoretical science a concept which has its roots in practical activity and which always bears the mark of its origin. Causal explanations necessarily (from the meaning of the word) spotlight a particular event or state of affairs and explain it in terms of temporally prior sufficient conditions; but theoretical sciences are not limited to this mode of explanation and have in fact tended to discard it in favour of other modes. (*See* below, *Historical Development.*)

Sense III: Cause as Explanation.—The word "cause" has also a wider use (sense III) in which it is equivalent to "explanation," whether or not the explanation is causal in senses I or II. Thus the word "because" can be used to introduce any type of answer to a question beginning "Why?" In this sense a cause need not be an action or event, but may be a state of affairs, a trait of character or, indeed, anything such that, if it were not present, the effect would not occur. Thus a husband's jealousy might be the cause of the breakdown of a marriage and the weakness of a link in a chain the cause of the chain's breaking. In the latter case the weakness of the link is not thought to be the sole cause; for, in calling it the cause, we do not intend to imply that no other conditions were necessary. We know that many factors must be present in the antecedent other than that called "the cause"; for example, the weak link would not have broken if no strain had been put on it. For this reason Mill thought that the selection of one factor as cause from a total set of antecedents was arbitrary.

There is, however, always a reason for our choice. We single out, as cause, that factor which it is possible or convenient for us to alter in order to produce or to prevent the effect. The breaking point of a chain is a function both of the strength of its weakest link and of the load put on it; consequently we can prevent the weak link's breaking again either by replacing it by a stronger one or by refraining from subjecting it to such heavy loads. We select the weakness of the link or the weight of the load as cause according to the remedy which it is most desirable to apply. Similarly, mosquitoes are said to cause malaria, although, for malaria to occur, there must be human bodies as well as mosquitoes; but it would be impolitic to try to abolish malaria by eliminating the human race. In this sense of "cause" alternative explanations do not exclude each other; any number of them can be true, and the cause will be relative to the interests and abilities of the investigator.

Historical Development.—The connection between the three senses seems probably to lie in the historical fact that, when the serious investigation of nature began in the 6th century B.C., it was customary to couch all explanations of natural events in anthropomorphic terms. The pattern of explanation appropriate to human action, which already contained the idea of cause (sense I), was thought applicable to natural phenomena; and, this being so, it was inevitable that the idea of cause (sense II) should retain the anthropomorphic elements of producing and compelling. The idea that a cause (sense II) is an agent which has the power to produce its effect or to compel it to occur bedevilled philosophical and scientific accounts of causation until the matter was clarified by David Hume (*see* below, *Hume's Criticism*) in the 18th century.

Cause from Aristotle to Copernicus.—For Aristotle all science was the search for causes (*i.e.*, explanations). His "four causes," which provided the framework of explanation until the 16th century, were four general types of answer to the question, "Why is something what it is?" Two of these causes, the material and the formal, we should regard as pertaining to the description of a thing rather than to a causal explanation of it. The material cause is the matter or "potential" from which the thing is made; the formal cause is, literally, the shape or, metaphorically, the structure or organizing principle which distinguishes it from other bits of the same matter (*see* FORM). Thus the material cause of a statue is a piece of bronze, the formal cause its human shape. A mathematical formula, for example the equation of a circle in Cartesian geometry, would be a formal cause.

Aristotle's efficient and final causes, on the other hand, correspond more closely to our uses of "cause." The efficient cause is the agent (*e.g.*, the sculptor) who brings the thing into being or imposes the form on the matter: the final cause is the purpose for which the thing is produced. That the whole scheme is anthropomorphic is shown both by the presence of the idea of "producing" in efficient cause and also by the fact that the final cause was thought to be, in the last resort, the only complete and satisfactory explanation of why a thing is what it is. The underlying idea is that everything does what it does because it is trying to achieve its purpose. In particular, all motion is explained as being due to a thing's attempt to come to rest at its natural resting place.

Cause in Renaissance Science.—In the period from Copernicus to Sir Isaac Newton the concept of causation underwent a change that may be described as the progressive elimination of the anthropomorphic elements in the Aristotelian conception. Two main strands can be detected in this change: (1) the attempt to refine the concept of cause (sense II) in such a way as to make it suitable for the purposes of theoretical science (*see* below, *The Refined Concept*); and (2) the transition from explanations in terms of efficient causes to explanations in terms of law.

Although the Aristotelian conception of explanation dominated the middle ages, a minority of mathematically minded scientists continued to follow the tradition of Pythagoras and Plato. According to this tradition, to explain a phenomenon is to discover the laws which it obeys. The astronomer Ptolemy, in the 2nd century A.D., maintained that it was legitimate to interpret the facts of planetary motion by means of any mathematical scheme which would "save the phenomena"; and Copernicus' heliocentric theory was accepted in the first instance, not because it was experimentally verified, but because it saved the phenomena with greater mathematical elegance than did its rivals. The 15th and 16th

centuries witnessed a great revival of Platonism; Johann Kepler equated "causes" with "reasons" and regarded the cause of planetary motion as a set of laws from which the observed movements of the planets can be deduced. This view introduces the idea of necessity into that of causation, first in an anthropomorphic sense as the necessity by which objects are compelled to obey God's laws and secondly as the logical necessity which relates premisses to conclusions.

The transition from explanations in terms of efficient causes to explanations in terms of law was largely the work of Galileo. From the point of view of an analysis of causation the importance of his work is threefold. In the first place, he undermined Aristotelian explanations of why things move as they do by showing in a series of experiments that they do not move in the ways which the explanations presuppose. This discredited the whole enterprise of explaining phenomena in terms of final causes and thereby opened the way for other types of explanation. Secondly, the substitution of exact description for explanation (or, as it is sometimes put, of the question "How?" for the question "Why?") led eventually to a conception of science in which all explanation just *is* description. A phenomenon is now said to be explained when the regularity which it exemplifies is able to be incorporated into a system of laws, for example, by being shown to be a logical consequence of those laws. In this way Kepler's laws of planetary motion, which are compendious ways of describing the movements of the known planets, are said to be explained when they are shown to follow from Newton's general laws of motion when constants are substituted for the variables in Newton's laws. Thirdly, Galileo and his contemporaries limited their descriptions to those aspects of phenomena that can be measured, and the spectacular success of physics resulted in its being taken as a model for all the theoretical sciences. Hence scientific explanation came to be thought of as the discovery of functional correlations between variables, a conception from which the idea of efficient cause has disappeared.

Cause in Newton's Philosophy.—The full implications of this revolution in theoretical science were not, however, appreciated at the time. In Newtonian physics, the concept of efficient cause, with its attendant idea of "production" and the contrast between "caused" and "free," still survives as an anomalous element. In the first law of motion, "free motion" is said to be uniform motion in a straight line, and forces are introduced as the causes of deviation from free motion. All observed motions can be analyzed into two components, a free component (inertia) and a component due to a force acting. The second law states that the force acting on a body is always proportional to the product of its mass and acceleration; but Newton never regarded the word "force" just as a name for this product. As a natural scientist he eschewed speculation into the nature of forces, thinking it sufficient for scientific purposes that we should be able to calculate and observe their effects. But he always regarded a force as an unknown somewhat which is the efficient cause of observed motion.

In a modern statement of Newtonian mechanics this conception of forces as efficient causes disappears, what remains being a set of differential equations correlating the total state of an isolated system at any one time with its total state at any other time. An example will help to make this clear. Consider a moving billiard ball striking another which is at rest. From the point of view of common sense the movement of the first ball up to the moment of impact is one event (the cause) and the movements of the two balls after impact is another, complex event (the effect). From the standpoint of classical mechanics, however, the system is not divided into two events. It is considered as a single system in which there is at every time the same quantity of momentum. From the equations of motion of the system together with a specification of the position and velocity of each body in it at any given time, we can calculate (if we disregard disturbing factors such as friction) the position and velocity of each body in the system at any other time. Since the laws of mechanics are reversible in respect of time, the division of the system into an earlier and a later phase is irrelevant.

These two explanations do not conflict with one another and it would be a mistake to say that, if the explanation furnished by classical mechanics is true, the common sense explanation must be false. The concept of cause reappears naturally in any practical or diagnostic application of the laws of mechanics. For, if I want to impart a given velocity to the second ball, the laws of mechanics enable me to calculate the momentum that must be introduced into the system by the movement of my arm. Similarly, if I want to explain why the second ball moved as it did, I can calculate by means of the laws of mechanics the velocity with which a ball of known mass must have struck it.

The Refined Concept of Cause.—We must now return to the attempt to refine the concept of cause (sense II) for the purposes of theoretical science. It is this attempt that gives rise to most of the traditional philosophical problems about causation. These problems are mainly due (1) to a confusion between cause in sense II and cause in sense III whereby some philosophers have been led to suppose that all explanations of natural phenomena must be causal in sense II; and (2) to the retention of the elements of "producing" and "compelling" from sense I. Hobbes defined a cause as "the aggregate of all the accidents both of the agents how many so ever they be, and of the patient, put together; which when they are all supposed to be present, it cannot be understood but that the effect is produced at the same instant: and if any one of them be wanting, it cannot be understood but that the effect is not produced." The word "accident" is here used in a technical sense in which it is roughly equivalent to "quality."

This concept of cause resembles the unrefined concept (sense II) in that causal statements are made in qualitative, not quantitative, terms and in that it retains the idea of "producing." It differs, however, from the unrefined concept in many important ways. The causal relation is said to be logically necessary: the cause is a necessary as well as a sufficient condition of the effect, and cause and effect are contemporaneous. These ill-assorted elements cannot in fact be comprised within a single concept and it is not difficult to deduce absurdities from a concept so composed.

We have already seen that a cause in sense II is necessarily prior to its effect in time and that it is one element singled out from the total antecedent of the effect, the selection being relative to the interests and abilities of the investigator. We have also seen that the effect had to be more or less vaguely specified. In the refined concept both cause and effect must be precisely specified and the cause is the total necessary and sufficient condition. It now follows that cause and effect must be instantaneous events and must be contemporaneous with each other. For, if the cause has duration, however short, it cannot in its earlier phases be sufficient to produce its effect, since the effect does not occur. The total antecedent only becomes sufficient at the instant the effect occurs: at any prior time the supposed cause is not sufficient to produce the effect, and it follows that cause and effect must be contemporaneous. If this is so, the cause of the cause must be contemporaneous with it; so all causes and effects will be contemporaneous.

From argument such as this some philosophers have tried to prove the unreality of time and change; but all such arguments are illegitimate in that they depend on employing a concept of cause that contains self-contradictory elements. We cannot employ both the idea of producing and the idea of a total set of necessary and sufficient conditions in the same concept, since the idea of producing is essentially that of an action which, supervening on a given set of conditions, is followed by an event which would not have occurred if the action had not supervened, while the idea of a total set of necessary and sufficient conditions requires cause and effect to be contemporaneous.

Hume's Criticism of the Concept of Cause.—The full implications of the revolution in physics outlined above were first appreciated by David Hume, who showed in the first place that the relation of cause and effect is neither logically necessary nor observable in a single instance. It is not logically necessary since we can conceive of an event's being preceded by any other event whatsoever, and what we can conceive could (logically) occur. If in fact an event of a certain type is always preceded by the same other type of event, we only know this from experience.

Equally, the relation is not observable in a single instance since all that we observe in an instance is a succession of events; we do not observe in the earlier event that "power" or "agency" which is essential to the concept of cause. And if we cannot observe this in a single instance we cannot observe it in any number of instances. Nevertheless, Hume knew that when we call something a cause we intend to assert more than temporal priority and contiguity in time and place. The third element, which he called "necessary connection," had been thought to lie in the "efficacy" or "productive power" of the cause. But Hume saw that, divorced from their associations with human action, words such as "efficacy," "agency," "power" and "production" are mere synonyms for the necessary connection that they are supposed to explain. Finally Hume came to the view that for an assertion of causality we require, besides contiguity and succession, only that the succession should have been repeated many times without any contrary instance; and he held that the idea of necessary connection was the determination of the mind to pass from the idea of the cause to that of the effect. An assertion of cause is an expression of confident expectation based on habit.

As a contribution to the problem of induction Hume's analysis was of the greatest importance; but as an explanation of the idea of necessary connection it seems inadequate. Hume failed to notice that this idea is really that of logical necessity transported from its proper place in a deductive system to an improper place in causal (sense II) explanations. When we say that the planets "must" move as they do, we do not mean that they are compelled to do so by efficient causes; we mean that the description of their observed motions follows logically from the laws of motion that we have adopted. The planets must move as they do, *if* Newton's laws are true and if the observations from which their movements are predicted were correct.

Following Hume, J. S. Mill defined the cause of a phenomenon as "the antecedent or concurrence of antecedents on which it is invariably and unconditionally consequent." The word "unconditionally" reintroduces the confusions inherent in the refined concept of cause. Since Mill was mainly interested in the social sciences, his theory represents a trend away from explanations in terms of mathematically formulated laws toward the older view of causation as a relation between events qualitatively described. His canons of induction require the analysis of complex events into factors and the discovery, by observation and experiment, of those factors which are invariably and unconditionally present when a certain phenomenon occurs and absent when it does not occur. Such an analysis, however, cannot be exhaustive without introducing the absurdities involved in the concept of an unconditional cause. Mill's canons of induction are useful in ordinary life and in the practical sciences, in fact wherever we are operating with the concept of cause (sense II) and do not attempt to refine it by requiring the cause to be necessary, sufficient and unconditional.

The Present State of the Question.—The notion of efficient cause survives in our ordinary language in such words as "produce," "bring about," "make," "due to," "result of" and "consequence of" and in the host of more specialized causal verbs. When the subject of these verbs is an inanimate thing the anthropomorphic element is a mere linguistic survival and does not (for most people) express anything present in thought: the cause is simply thought of as a sufficient condition discovered to be sufficient by experience. In ordinary life we are not troubled by the logical problem of induction; that is to say, we do not stop to ask why the fact that a succession of events has been observed to occur many times should justify our expectation that it will occur again. The examination of this problem is beyond the scope of this article. (*See* INDUCTION.)

In the sciences, explanations are mostly of the type known as "hypothetico-deductive," according to which observation suggests a generalization or law from which consequences can be deduced. The consequences can then be verified or falsified by controlled experiment or, where this is impossible, by observation. In the theoretical sciences, generalizations and laws usually take the form of functional correlations between variables, and the idea of efficient cause does not appear. Any set of laws which saves the phenomena is considered legitimate; but since a given set of phenomena can be saved by any of an infinite number of alternative sets of laws it is necessary to provide criteria for choosing one set rather than another. The usual criteria are mathematical simplicity (which is largely a matter of taste), comprehensiveness and predictive fruitfulness. The concept of efficient cause still appears within this framework in those sciences which depend largely on qualitative analysis and, especially, in the practical sciences.

CAUSE AND EFFECT: *see* CAUSALITY OR CAUSATION.

CAUSEWAY. A path on a raised dam or mound across marshes or low-lying ground; the word is also used of old paved highways, such as the Roman military roads. "Causey" is still used dialectically in England for a paved or cobbled footpath. The word is properly "causey-way," from *causey*, a mound or dam which is derived, through the Norman-French *caucie* (*cf.* modern *chaussée*), from the late Latin *via calciata*, a road stamped firm with the feet (*calcare*, to tread).

CAUSSES, a natural region in the south of the central plateau of France, chiefly in the departments of Lozère and Aveyron, west of the curving Cevennes and south of the Lot valley. This vast plateau of Jurassic limestone, sloping westward, is divided into several sections by deep-cut river channels. These smaller plateaus, barren and deserted, are called the *Causses* from *cau*, the local form of the French *chaux* (*i.e.*, lime). The most typical is the Causse Méjan, south of the Tarn between Florac and Millau, a sterile sparsely peopled tableland lying between 3,000 and 4,000 ft. above sea level. To the north lies the Causse de Sauveterre prolonged westward by the Causse de Sévérac. Those of Quercy, Gramat and Rouergue are lower and less arid. Drainage features such as underground streams, fissures and potholes (*avens*) are characteristic. The inhabitants (Caussenards) cultivate rye and potatoes where possible but subsist for the most part on the sheep from whose milk Roquefort cheese is made. Similar dry limestone areas elsewhere are designated under the cognate German *Karst* or Italian *Carso* (*qq.v.*).

CAUSSIN DE PERCEVAL, ARMAND PIERRE (1795–1871), French orientalist, was born in Paris and died there during the siege.

After extended travels in Asia Minor, he succeeded his father Jean Jacques (1759–1835) as professor of Arabic at the Collège de France.

His works include a useful *Grammaire arabe vulgaire* (4th ed., 1858), and an enlarged edition of Élie Bocthor's *Dictionnaire français-arabe* (3rd ed., 1864); but his great reputation rests on his *Essai sur l'histoire des Arabes avant l'Islamisme, pendant l'époque de Mahomet*, 3 vol. (1847–49), in which the native traditions as to the early history of the Arabs, down to the death of Mohammed and the complete subjection of all the tribes to Islam, are set forth with much learning and lucidity.

CAUSTIC. That which burns (Gr. καυστικός, burning). In *surgery*, the term given to substances which destroy living tissues and so inhibit the action of organic poisons, as in bites, malignant disease and gangrenous processes. Such caustic substances include silver nitrate (lunar caustic), potassium and sodium hydrates (the caustic alkalis) (*see* ALKALI), zinc chloride, an acid solution of mercuric nitrate, and pure carbolic acid (phenol).

In *mathematics*, the "caustic surfaces" of a given surface are the envelopes of the normals to the surface, or the loci of its centres of curvature.

In *optics* (geometrical optics) the term "caustic" is applied to the envelope of luminous rays after reflection or refraction. In the first case the envelope is termed a cata-caustic, in the second a dia-caustic. Cata-caustics are to be observed as bright

curves when light is allowed to fall on a polished cylindrical surface as a napkin ring or a curved polished riband of steel placed on a table. By varying the curvature of the riband of steel or moving the source of light a variety of patterns can be obtained. The investigation of caustics, based as it is on the assumption of the law of the rectilinear propagation of light and the validity of the experimental laws of reflection and refraction, is essentially of a geometrical nature, and as such attracted the attention of mathematicians of the 17th and succeeding centuries, more notably John Bernoulli, G. F. de l'Hopital, E. W. Tschirnhausen and Louis Carre.

See Arthur Cayley, *Memoirs on Caustics* in Phil. Trans. for 1857 and 1867.

CAUSTIC SODA (sodium hydroxide, NaOH) is a solid, white, deliquescent chemical compound much used as an intermediate material in the production of many chemicals. It is generally made by one of two methods, either through exchange of base by the causticizing of soda-ash (Na_2CO_3) with hydrated lime or directly, through the action of an electric current upon a solution of common salt (NaCl). The latter newer process is tending to supersede the former, especially where cheap electric power is available or where a ready market for chlorine and hydrogen, by-products of the electrolytic process, exists. Because of its large production, caustic soda is classed as a "heavy chemical." It is used as an alkaline reagent, in the manufacture of soap, sodium salts, rayon, paper, medicines, textile products, in petroleum and vegetable oil refining, in tanning and in the synthesis of many organic compounds such as indigo, alizarin, resorcin, formates and oxalates.

CAUTERETS, a watering place of southwestern France in the department of Hautes-Pyrénées, 20 mi. S.W. of Lourdes by rail. Pop. (1946) 1,012. It lies in the beautiful valley of the Gave de Cauterets, and is well known for its thermal springs, and as a station for winter sports. About 50,000 visitors are attracted annually. The 22 springs produce copious supplies of sulphuretted water and serve nine *établissements*. Their temperature varies between 75° and 137°. Cauterets is a centre for excursions, the Monné (8,937 ft.), the Cabaliros (7,651 ft.), the Pic de Chabarrou (9,550 ft.), the Vignemale (10,820 ft.), and other summits being in its neighbourhood. The properties of the waters have been known at least since the 10th century. They became famous in the 16th century when Marguerite de Valois composed the "Heptameron," on the model of Boccaccio's "Decameron," while visiting the spa with her court.

CAUTÍN, a province of southern Chile, bounded north by Malleco and Arauco, east by Argentina, south by Valdivia, and west by the Pacific. Area 6,707 sq.mi.; pop. (1952 census) 365,072, including many European immigrants, principally Germans. Cautín lies within the temperate rain forest region of the south, its chief products are timber, cattle, grain and apples. The state railway from Santiago to Puerto Montt crosses the province from north to south; branch lines to such places as Cherquenco, Cunco, Tolten and Carahue provide good rail service to most parts of the province. Two partially navigable rivers cross the province from east to west, the Tolten and the Cautín, the lower reaches of the latter being known as the Río Imperial. The province once formed part of the territory occupied by the Araucanian Indians, and Temuco, the capital of the province, long remained the centre of greatest concentration of these people. Temuco, a city of 51,497 inhabitants in 1952, is on the Río Cautín. It is an important rail centre, market town, and gateway to the famous lake district of south Chile.

CAUTLEY, SIR PROBY THOMAS (1802–1871), English engineer and palaeontologist, was born in Suffolk in 1802. After several years' service in the Bengal artillery, which he joined in 1819, he was engaged on the reconstruction of the Doab canal. He had charge of the completed canal for 12 years (1831–43). In 1840 he reported on the proposed Ganges canal, for the irrigation of the country between the rivers Ganges, Hindan, and Jumna. This project was sanctioned in 1841, but work was not begun until 1843, and even then Cautley found himself hampered in its execution by the opposition of Lord Ellenborough. For want of competent help he had to do the drudgery of surveying and levelling himself, for some time. From 1845 to 1848 he was in England because of ill-health, and on his return to India he was appointed director of canals in the North-West Frontier Province. After the Ganges canal was opened in 1854 he spent some time in England, and from 1858 to 1868 he occupied a seat on the council of India. He died at Sydenham, near London, on Jan. 25, 1871. Cautley was a distinguished palaeontologist and contributed numerous memoirs, some written in collaboration with Hugh Falconer, to the *Proceedings* of the Bengal Asiatic society and the Geological Society of London on the geology and fossil remains of the Sivalik hills.

CAUVERY (KAVERI), a river of southern India. Rising in Coorg, high amid the Western Ghats, in 12° 25′ N. lat. and 75° 34′ E. long., it flows generally southeast across the plateau of Mysore, and finally enters the Bay of Bengal through two principal mouths in Tanjore district. Its length is 472 mi. Its course in Coorg is tortuous, and its bed generally rocky with high banks covered with luxuriant vegetation. On entering Mysore it passes through a narrow gorge, then widens to a breadth of 300 to 400 yd. The bed is too rocky for navigation. In its course through Mysore the channel is interrupted by a number of anicuts or dams for irrigation. In Mysore the Cauvery forms the two islands of Seringapatam and Sivasamudram, which vie in sanctity with Srirangam Island lower down in Trichinopoly district. Around Sivasamudram Island are the celebrated falls of the Cauvery, where the river branches into two channels, each making a descent of about 320 ft. After entering Madras state, the Cauvery forms the boundary between the Coimbatore and Salem districts, until it reaches Trichinopoly district. Sweeping past the historic rock of Trichinopoly, it again breaks at Srirangam Island into two channels, which enclose between them the delta of Tanjore, the garden of southern India. The northern and larger channel is called the Coleroon (Kolidam). On the seaward side of the delta are the open roadsteads of Negapatam and Karikal. The only navigation on any part of its course is carried on in basket work boats.

There is an extensive irrigation system in the delta. The Grand anicut (or weir), built in the 2nd century where the Cauvery divides into two channels, feeds the deltaic irrigation system of Tanjore. A second anicut across the Coleroon (1836–38) was necessary to save the old system from the disaster of silting, but it also added to the irrigated area. The Mettur project, a dam and canal more than 200 mi. from the sea, was completed in 1938. It improved the water supply to more than 1,000,000 ac. already irrigated, added another 300,000 ac. and provided 50,000 kw. of electric power, thus creating an important industrial area. The Cauvery falls, under an older power scheme, provide electricity to Mysore and Bangalore and the Kolar gold mines.

The Cauvery is known to devout Hindus as Dakshini Ganga, or the Ganges of the south, and its entire course is holy ground. (T. HER.)

CAVA DEI TIRRENI, a town and episcopal see of Campania, Italy, in the province of Salerno, 6 mi. N.W. by rail from the town of Salerno. Pop. (1951), commune, 39,086. It lies fairly high in a richly cultivated valley, surrounded by wooded hills, and is a favourite resort. A mile to the southwest is the village of Corpo di Cava (1,970 ft.), with the Benedictine abbey of La Trinità della Cava, founded in 1025 by St. Alferius. The church and the greater part of the buildings were entirely modernized in 1796. The old Gothic cloisters are preserved. The archives, now national property, include documents and manuscripts of great value.

M. Morcaldi, *Codex Diplomaticus Cavensis* (1873–93) published many important documents relating to the abbey.

CAVAEDIUM, in architecture, a synonym for atrium (*q.v.*), the central hall or court of a Roman house. Vitruvius lists five types: (1) The Tuscanicum. This, the most common type, was without columns, the hole in the roof being supported by the framing of the roof timbers. (2) The Tetrastylon, in which four columns supported the roof at the corners of its opening. (3) The Corinthian, in which more than four columns are employed, so that the cavaedium becomes, in essence, a peristyle (*q.v.*). (4) The Displuviatum, where the roof sloped down, away from the opening, instead of toward it. (5) The Testudinatum, in which the entire area was covered by a continuous roof.

CAVAGNARI, SIR PIERRE LOUIS NAPOLEON (1841–1879), British military administrator, the son of a French general by his marriage with an Irish lady, was born at Stenay,

Meuse, on July 4, 1841. He obtained naturalization as an Englishman, and entered the military service of the East India Company. He served through the Oudh campaign against the mutineers in 1858 and 1859. In 1861 he was appointed an assistant commissioner in the Punjab, and in 1877 became deputy commissioner of Peshawar and took part in several expeditions against the hill tribes. In 1878 he was attached to the staff of the British mission to Kabul, which the Afghans refused to allow to proceed. In May 1879, after the death of the amir Shere Ali, Cavagnari negotiated and signed the treaty of Gandamak with his successor, Yakub Khan. By this the Afghans agreed to admit a British resident at Kabul, and Cavagnari was appointed. He took up his residence in July, and for a time all seemed to go well, but on Sept. 3 Cavagnari and the other European members of the mission were massacred in a sudden rising of mutinous Afghan troops. (*See* AFGHANISTAN.)

CAVAIGNAC, LOUIS EUGÈNE (1802–1857), French general, born in Paris on Oct. 15, 1802, belonged to a family famous in French revolutionary annals. He was the son of JEAN-BAPTISTE CAVAIGNAC (1762–1829), who was a member of the Convention, and acted as its commissioner in the repression of the opponents of the Revolution in various parts of France. At the Restoration he was proscribed as a regicide. Jean-Baptiste's brother, JACQUES MARIE, VICOMTE CAVAIGNAC (1773–1855), was one of Napoleon's generals and commanded the cavalry of the 11th Corps in the retreat from Moscow (1812). GODEFROY CAVAIGNAC (1801–1845), elder brother of Louis Eugène, took part in the Parisian risings of Oct. 1830, 1832 and 1834, and was one of the founders of the Société des Droits de l'Homme. Very highly esteemed for his chivalrous character among the republicans, he was probably personally both the most estimable and able of the old guard of republicans. His reputation was largely, if not wholly, responsible later for the advancement of Louis Eugène, who entered the army.

In 1831 Louis Eugène was removed from active duty in consequence of his declared republicanism, but in 1832 he was recalled to the service and sent to Algeria, where he held a series of commands during the next 16 years. In 1848, the revolutionary Government promoted him governor-general. He refused the post of minister of war because the Government would not fall in with his plan to occupy Paris by troops. Like L. A. Thiers, Cavaignac conceived the idea of drawing the "red republicans" of Paris out into open insurrection, in order that they might be crushed and the domination of the moderates secured. After the National Assembly had eliminated the Socialist members Louis Blanc and Albert (*qq.v.*) from the Government, Cavaignac was made minister of war. The revolt on which he had calculated broke out on June 22, 1848 (*see* NATIONAL WORKSHOPS). Cavaignac withdrew his troops from the affected parts of Paris, till, in his opinion, the revolt had gained sufficient head. He took advantage of the general panic, further, to insist on the resignation of the Government and the granting of dictatorial powers to himself, which was agreed on June 25. His attack on the Parisian rebels, who were exclusively working class, led to the bloodiest and most obstinate conflict that had up till then occurred in Paris; at its end, in his victory on the 26th, Cavaignac permitted, in accordance with his plan, the severest reprisals which decimated the ranks of the Socialists and broke their power.

Both he and his adversaries expected that after laying down his dictatorship he would be elected president. But they had not allowed for the magic of the name of "Louis Napoleon Bonaparte"; a "landslide" of peasant and proletarian votes gave 5,434,226 to the future Napoleon III. and only 1,448,107 to Cavaignac. The disappointed general went into opposition and at the time of the *coup d'état* (Dec. 2, 1851) was even imprisoned for a short while. After his release he abandoned politics and died in retirement on Oct. 28, 1857.

See Louis Menard, *Prologue d'une Révolution* (reprinted 1904); Ch. Schmidt, *Les Journées de juin 1848* (1926); P. de la Gorce, *Histoire de la 2de République* (1914); G. Renard, *La République de 1848* (1900–8); R. W. Postgate, *Revolution from 1789 to 1906* (1920, full bibliog.).

His son, JACQUES MARIE EUGÈNE GODEFROI CAVAIGNAC (1853–1905), French politician, was born in Paris on May 21, 1853. He served as a civil engineer in Angoulême until 1881, when he became master of requests in the Council of State. In 1882 he was elected deputy for Saint-Calais (Sarthe) in the republican interest. In 1885–86 he was under-secretary for war in the Henri Brisson Ministry, and he served in the cabinet of Émile Loubet (1892) as minister of marine and of the colonies. He had exchanged his moderate republicanism for radical views before he became war minister in the cabinet of Léon Bourgeois (1895–96). He was again minister of war in the Brisson cabinet in July 1898, when he read in the chamber a document which definitely incriminated Capt. Alfred Dreyfus. On Aug. 30, however, he stated that this had been discovered to be a forgery by Col. Henry, but he refused to concur with his colleagues in a revision of the Dreyfus prosecution, which was the logical outcome of his own exposure of the forgery. Resigning his portfolio, he joined the Nationalist group in the chamber, and became an energetic supporter of the Ligue de la Patrie Française. In 1899 Cavaignac was an unsuccessful candidate for the presidency of the republic. He died at his country-seat near Flée (Sarthe) on Sept. 25, 1905. He wrote an important book on the *Formation de la Prusse contemporaine* (1891–98), dealing with the events of 1806–13.

See J. M. Cavaignac, *Les deux généraux Cavaignac* (1897); A. Deschamps, *Les deux généraux Cavaignac* (1898); W. Arnoulim, *L'Action clericale en France, Les Cavaignacs devant l'histoire* (1905).

CAVAILLON, a town of south-eastern France in the department of Vaucluse, 20 mi. S.E. of Avignon. Pop. (1936), 8,452. It lies at the southern foot of Mount St. Jacques on the right bank of the Durance above its confluence with the Coulon. To the south of the present town lay the Roman *Cabellio,* a place of some note in territory of the Cavares. Since mediaeval times the town has for the most part followed the fortunes of the Comtat Venaissin, in which it was included. Till the Revolution it was the see of a bishop, and had a large number of monastic establishments. The church of St. Véran is a fine example of 12th century Provençal architecture, with a cloister adjoining. The town is the centre of a rich and well-irrigated plain, which produces fruits and early vegetables. Silk-worms are reared, and silk is an important article of trade. The preparation of preserved vegetables and fruits, distilling and the manufacture of straw hats and leather are carried on.

CAVALCANTI, GUIDO (*c.* 1250–1300), Italian poet and philosopher, was the son of a philosopher whom Dante, in the *Inferno,* condemns to torment among the epicureans and atheists; but he himself was a friend of the poet. By marriage with Beatrice, daughter of Farinata Uberti, he became head of the Ghibellines. He was banished to Sarzana, where he caught a fever, of which he died. Cavalcanti has left a number of love sonnets and canzoni, in honor of a French lady, whom he calls Mandetta. His complete poetical works are contained in Giunti's collection (Florence, 1527; Venice, 1531–32).

The most famous of his sonnets and canzoni are translated by D. G. Rossetti in his *Dante and his Circle* (1874).

CAVALCASELLE, GIOVANNI BATTISTA (1820–1897), Italian writer on art, was born at Legnago on Jan. 22, 1820. He became a student at the Academia delle Belle Arti in Venice, and from early youth studied the art treasures of Italy. His relations sent him to Padua, hoping that he might become an engineer, but in 1844 he returned to his artistic studies. He visited the cities of Tuscany, and then set out to see the masterpieces of Italian art in foreign countries. During a stay in Germany in 1846 and 1847 he made the acquaintance of Joseph Archer Crowe in a post carriage between Hamm and Minden. The two young men felt drawn to each other and met again in Berlin, where they studied together some pictures in the museum. On his return to Venice Cavalcaselle took an active part in the revolution of 1848 against the Austrian rule. He was arrested by Austrian gendarmes and narrowly escaped being shot. He then joined the forces of Garibaldi and was taken prisoner by the French in 1849. He arrived in a miserable plight in Paris, where by good fortune he again met Crowe, and with his help came to

London. The two friends occupied rooms together and worked on a history of early Flemish painters, published in 1857. In the same year Cavalcaselle returned to Italy. In 1864 Crowe and Cavalcaselle published their great work, *New History of Italian Painting*, which was followed by the *History of Painting in North Italy*. Other joint works were *Titian* (1876) and *Raphael* (1883). Cavalcaselle's independent writings are of less importance: *Sul più autentico ritratto di Dante* (1865); *Sulla conservazione dei Monumenti ed oggetti di belle arti; Sulle riforme dell' insegnamento academico* (1875).

Cavalcaselle was for some time secretary to the great art critic and collector, Giovanni Morelli, and his travelling companion when Morelli compiled the inventory of the works of art in the Marca d'Ancona for the Italian Government. Towards the end of his life Cavalcaselle held office as ispettore di belle arti in the Ministry of Education in Rome. He died on Oct. 31, 1897.

Crowe and Cavalcaselle's histories of Italian art are standard works, and have recently been re-edited by Langton Douglas and Tancred Borenius.

CAVALIER, JEAN (1681–1740), the famous chief of the Camisards (*q.v.*), was born at Mas Roux, near Anduze (Gard), on Nov. 28, 1681. His father, an illiterate peasant, had been compelled by persecution to become a Roman Catholic along with his family, but his mother brought him up secretly in the Protestant faith. Threatened with prosecution for his religious opinions he went to Geneva, where he passed the year 1701; he returned to the Cévennes on the eve of the rebellion of the Camisards, who by the murder of the Abbé du Chayla at Pont-de-Monvert on the night of July 24, 1702, raised the standard of revolt. Some months later he became their leader. He showed an extraordinary genius for war. Within a period of two years he was to hold in check Count Maurice de Broglie and Marshal Montrevel, and to carry on one of the most terrible partisan wars in French history.

He maintained the most severe discipline. Each battle increased the terror of his name. On Christmas day, 1702, he dared to hold a religious assembly at the very gates of Alais, and put to flight the local militia which came forth to attack him. At Vagnas, on Feb. 10, 1703, he routed the royal troops, but, defeated in his turn, he was compelled to find safety in flight. But he reappeared, was again defeated at Tour de Bellot (April 30), and again recovered himself, recruits flocking to him to fill up the places of the slain. Cavalier boldly carried the war into the plain, made terrible reprisals, and threatened even Nîmes itself. On April 16, 1704, he encountered Marshal Montrevel himself at the bridge of Nages, with 1,000 men against 5,000, and, though defeated after a desperate conflict, he made a successful retreat. Cavalier was induced to attend a conference at Pont d'Avène near Alais on May 11, 1704, and on May 16, he made submission at Nîmes. Louis XIV. gave him a commission as colonel, which Villars presented to him personally, and a pension of 1,200 livres. At the same time the king authorized the formation of a Camisard regiment for service in Spain under his command.

Before leaving the Cévennes for the last time he went to Alais and to Ribaute, followed by an immense concourse of people. But Cavalier had not been able to obtain liberty of conscience, and his Camisards almost to a man broke forth in wrath against him, reproaching him for what they described as his treacherous desertion. On June 21, 1704, with a hundred Camisards who were still faithful to him, he departed from Nîmes and came to Neu-Brisach (Alsace), where he was to be quartered. From Dijon he went on to Paris, where Louis XIV. gave him audience and heard his explanation of the revolt of the Cévennes. Returning to Dijon, fearing to be imprisoned in the fortress of Neu-Brisach, he escaped with his troop near Montbéliard and took refuge at Lausanne. But he was too much of a soldier to abandon the career of arms. He offered his services to the duke of Savoy, and with his Camisards made war in the Val d'Aosta. After the peace he crossed to England, where he formed a regiment of refugees which took part in the Spanish expedition under the earl of Peterborough and Sir Cloudesley Shovel in May, 1705. At the battle of Almansa the Camisards found themselves opposed to a French regiment, and without firing the two bodies rushed one upon the other. "I fought," Cavalier wrote on July 10, "as long as a man stood beside me and until numbers overpowered me, losing also an immense quantity of blood from a dozen wounds which I received." Marshal Berwick never spoke of this tragic event without visible emotion.

On his return to England a small pension was given him. He settled at Dublin, where he published *Memoirs of the Wars of the Cévennes under Col. Cavalier*, written in French and translated into English with a dedication to Lord Carteret (1726). He was made general on Oct. 27, 1735, and on May 25, 1738, was appointed lieutenant-governor of Jersey. He was promoted major-general in July, 1739, and died in the following year.

See N. A. F. Puaux, *Vie de Jean Cavalier* (1868); David C. A. Agnew, *Protestant Exiles from France*, ii. 54–66 (1871); Charvey, *Jean Cavalier: nouveaux documents inédits* (1884). Eugène Sue popularized the name of the Camisard chief in *Jean Cavalier ou les fanatiques des Cévennes* (1840). A new edition of Cavalier's *Mémoires sur la guerre des Cévennes* was published by F. Puaux in 1918.

CAVALIER, a horseman, particularly a horse-soldier or one of gentle birth, trained in knightly exercises. The word is taken through the French from the Late Lat. *caballarius*, a horseman. *Chevalier*, the French word of parallel descent, means "knight," and is chiefly used in English for a member of certain foreign military or other orders, particularly of the Legion of Honour. Cavalier in English was early applied in a contemptuous sense to an overbearing swashbuckler. Originally used as a term of reproach, it was soon adopted as a title of honour by the supporters of Charles I. in the Great Rebellion, who applied Roundhead to their opponents, and at the Restoration the court party preserved the name, which survived till the rise of the term Tory (*see* WHIG AND TORY). The term "cavalier," in fortification, means a work of great command constructed in the interior of a fort, bastion or other defence, so as to fire over the main parapet without interfering with its firing. A greater volume of fire can thus be obtained, but the great height of the cavalier makes it an easy target for a besieger's guns.

CAVALIERI, BONAVENTURA (1598–1647), Italian mathematician, was born at Milan; his name also occurs in the forms Cavallieri, Cavaglieri, Cavalerius, and de Cavalerüs. He became a Jesuit at an early age and later was inspired to study mathematics by reading a copy of Euclid. On the recommendation of his Order he was made a professor at Bologna in 1629; the post, which he held until he died, was renewed periodically. In 1635 Cavalieri wrote *Geometria indivisibilium continuorum nova quadam ratione promota*, in which he first stated his principle of indivisibles. The form of the principle was unsatisfactory and was attacked by Guldin. In reply to this attack Cavalieri wrote *Exercitationes geometricae sex* (1647), stating the principle in the more satisfactory form in which it was used by 17th century mathematicians. This work also contained the first rigorous proof of Guldin's theorem relating to the volume of a solid of revolution. The theorem had occurred in the writings of Pappus and had been used in an unsatisfactory fashion by Kepler. Using the principle of indivisibles as a sort of integral calculus, Cavalieri solved a number of problems proposed by Kepler. Other books by Cavalieri are: *Lo specchio ustorio ovvero trattato delle settioni coniche* (1632), *Directorium generale uranometricum, in quo trigonometriae logarithmicae fundamenta ac regula demonstrantur* (1632) and *Trigonometria plana et sphaerica* (1643). Cavalieri died at Bologna on Dec. 3, 1647.

The life of Cavalieri has been written by P. Frisi (Milan, 1776), and by F. Predari (Milan, 1843).

CAVALIERI, EMILIO DEL (1550?–1599?), Italian composer, was born in Rome about 1550 of a noble family and became one of the famous Florentine group of musical reformers —Peri, Rinuccini, Caccini and the rest—who had such an important influence on the subsequent developments of the art.

Cavalieri's style is more facile than that of Peri and Caccini, but he is inferior to them in depth of musical expression. He is, however, important as having been the first to apply the new monodic style to sacred music, and as the founder of the Roman

school of the 17th century which included Domenico Mazzocchi, Giacomo Carissimi and Alessandro Scarlatti.

CAVALLI, FRANCESCO (1602–1676), an early Italian operatic composer of note, was born at Crema in 1602. His real name was Pietro Francesco Caletti-Bruni, but he is better known by that of Cavalli, the name of his patron, a Venetian nobleman. He became a singer at St. Mark's in Venice in 1617, second organist in 1639, first organist in 1665 and in 1668 *maestro di cappella.* He is, however, chiefly important for his operas, 27 of which are still extant, most of them being preserved in the library of St. Mark's at Venice.

Claudio Monteverdi had found opera a musico-literary experiment, and left it a magnificent dramatic spectacle.

Cavalli succeeded in making it a popular entertainment. He reduced Monteverdi's extravagant orchestra to more practical limits, introduced melodious arias into his music and popular types into his libretti. His operas have all the characteristic exaggerations and absurdities of the 17th century, but they have also a remarkably strong sense of dramatic effect as well as a great musical facility and a grotesque humour which was characteristic of Italian grand opera down to the death of Alessandro Scarlatti.

CAVALLINI, PIETRO (*c.* 1259–1344), Italian painter, born in Rome, was taught painting and mosaic by Giotto di Bondone while employed at Rome; it is believed that he assisted his master in the mosaic of the Navicella or ship of St. Peter, in the porch of the church of that saint. He also studied under the Cosmati. Luigi Lanzi describes him as an adept in both arts, and mentions with approbation his grand fresco of a crucifixion at Assisi, still in tolerable preservation; he was, moreover, versed in architecture and in sculpture.

According to George Vertue, it is highly probable that Cavallini executed, in 1279, the mosaics and other ornaments of the tomb of Edward the Confessor in Westminster abbey. Cavallini would thus be the Petrus Civis Romanus whose name is inscribed on the shrine; but a comparison of dates invalidates this surmise.

He died in 1344 at the age of 85. Some important works by Cavallini in the church of Santa Cecilia in Trastevere, Rome, were discovered early in the 20th century.

CAVALLOTTI, FELICE (1842–1898), Italian politician, poet and dramatic author, was born in Milan. In 1860 and 1866 he fought with the Garibaldian corps, but he first attained notoriety by his antimonarchical lampoons in the *Gazzetta di Milano* and the *Gazzetta Roas* between 1866 and 1872. Elected to parliament in 1872, his turbulent eloquence secured for him the leadership of the extreme left in 1886 on Agostino Bertani's death. His advocacy of democratic reform made him the most popular man of his day next to Francesco Crispi, against whom he waged an unceasing and bitter campaign. He was killed in a duel with Count Macola.

See A. de Mohr, *Felice Cavallotti: La Vita e le opere* (Milan, 1899).

CAVALRY, known in most armies after World War II as armoured cavalry, constitutes one of the major ground combat arms of a military force and is the element the main duties of which are to furnish full terrestrial information of the enemy while screening the movements of its own army; to pursue and demoralize a defeated enemy; at all times to threaten and intercept his communications (lines of supply and command); in battle to strike suddenly and swiftly at weakened points, turn exposed flanks or force or exploit a penetration or breakthrough. While it could fight dismounted, cavalry originally was considered as an arm which fought on horseback, using the horse's mobility in manoeuvring and his impetus in charging.

By the middle of the 16th century the term cavalry was applied to mounted men of all kinds employed for combatant purposes. Cavalry missions have always required a high degree of mobility, and during the early part of the 20th century, in order to accomplish assigned tasks, the arm adopted fast-moving armoured vehicles. Cavalry operating entirely in armoured fighting vehicles became known as "mechanized cavalry" and subsequently as "armoured cavalry." The weapons of the armoured cavalry are tanks, self-propelled guns and howitzers, automatic weapons, mortars, rocket launchers, rifles, pistols, bayonets and grenades.

The U.S. army organization act of 1950 eliminated cavalry as a branch and provided for an armour branch, "a continuation of the cavalry."

History of Cavalry Tactics.—The two most primitive types of soldier are the foot soldier and the horse soldier, the first being characteristic of early European warfare, and the second of early Asiatic warfare, since in southern Europe (that is, in the countries south and west of the Danube and the Rhine) few suitable breeds of war horses existed—hence the poverty of Roman cavalry and of early Grecian cavalry. When infantry met infantry, battles were decided by numbers or armament or discipline; and when cavalry met cavalry, as in Scythia, battles were seldom decided at all, degenerating as they normally did into skirmishes, forays and scattered pursuits. In hilly country, such as most of Greece, cavalry were normally impotent to attack infantry, as is exemplified in the Graeco-Persian Wars (490–479 B.C.); while in open plain land, so frequently found in Asia Minor, they could destroy infantry by besieging them in the field, as happened to Crassus, at Carrhae in 53 B.C. The truth of the matter is that the two arms were complementary, each providing the other with powers not inherent in either separately. Infantry in an advance were useless unless their rear services were protected, and so also were cavalry in the advance, unless the positions won by them could be held so that their forward movement might not be interrupted.

The art of an advance through a hostile country has always pivoted on the power of pushing forward a secure and movable base in order to develop from it offensive power. Once infantry and cavalry were combined, the first formed the movable base, and the second provided the offensive power. The function of cavalry in any armed force was to fill that requirement of a balanced army which demands a fighting ground element superior to the main element—infantry—in mobility near and on the battlefield, and possessing in common with that arm the ability to engage in offensive and defensive fighting, whether independently or in conjunction with other arms.

When the advance merged into the attack, three targets would present themselves; namely, the enemy's infantry, his cavalry and his baggage train. If the third could be seized and held, the severest possible blow could be dealt the enemy's organization; consequently the supply services would be well protected by the battle front. Infantry could oppose infantry frontally, but if attacked in flank, or rear, by infantry or cavalry, they were taken at a tremendous disadvantage. Throughout history flank protection was furnished by cavalry. The infantry front may then be pictured as a slowly moving wall behind which were assembled the supply services, and on the flanks of which were hinged two cavalry wings, which, like doors, could swing forward and backward, "flapping" away any hostile force which might attempt to raid the baggage train, or attack the infantry in the rear. In battle, the first problem was, therefore, the destruction of one or both of the hostile cavalry wings, for when once the opposing infantry wall was bereft of its swinging doors, not only did its flanks become attackable, but also its rear. If, meanwhile, its front could be so firmly held that it was unable to change front, a cavalry attack on its flanks, or rear, was likely to prove decisive. In brief, the object of infantry was to provide a base of operations for cavalry; and the power of cavalry was to be sought, first in ability to overcome their like, and second in being able to develop a sufficiency of speed so as to circumvent an infantry front, and attack it in the rear before it could face about, which, in the case of an organized army, was an extremely difficult and dangerous operation; impossible if the front was firmly held.

Early Cavalry.—During the early classical age tactical organization was based on the nature of the country rather than on any idea of weapon co-operation or combination between the arms. Thus, in Sparta there was practically no cavalry, while in Scythia mounted bowmen alone existed. Nevertheless, as soon as the Asiatic horsemen came into contact with European foot soldiers, as took place in the 5th century B.C., the problem of tactical co-operation, namely, how to equip, arm and manoeuvre a body of men so that offensive power may be developed from a protec-

tive base, was thrust to the fore. This problem was solved by Philip of Macedon, and proved out by his son Alexander the Great.

The backbone of Philip's army was the phalanx, or infantry mass. Armed with the Sarissa, a pike from 18 to 21ft. long, it formed an impenetrable hedge of spears to cavalry attack, though it offered a somewhat vulnerable target to archers both mounted and on foot. To protect it from these, numbers of lightly armed infantry were attached to it, their duty being very similar to that of the British light infantry during the Peninsular War in Spain at the beginning of the 19th century. Recognizing the strong protective and resisting power which the phalanx possessed, Philip was one of the first among the ancients to grasp the fact that stability of organization alone is insufficient to guarantee the act of disruption being followed up by the act of annihilation. The phalanx could not pursue without breaking its formation, it was not armed for the pursuit, and in the pursuit, the pursued almost invariably moves faster than the pursuer, whether both be on foot or mounted. To render the act of annihilation possible, Philip added to the phalanx a superb force of cavalry in the proportion of one trooper to every six heavy foot soldiers. This cavalry he organized in three bodies: Heavy armoured cavalry for the charge, his Companion cavalry being the most notable corps; light cavalry, or Hussars, for reconnaissance and outpost work, and Dragoons who could fight on foot or on horseback. His heavy cavalry doctrine was profoundly simple—horse and rider combined were used as a "projectile" against the enemy once he was held by the phalanx, when the object of his cavalry became the annihilation of all resistance. The tactics which his son developed from this organization were equally simple, and astonishingly effective. Advancing in parallel order to his enemy, he obliqued his right, bringing it forward, and while his centre, protected on its left by the left cavalry wing, held the enemy to his ground, he delivered a series of terrific punches at his opponent's centre, or left, with a view to penetrate or envelop. At the battles of the Granicus (334 B.C.), Issus (333 B.C.), and Gaugamela (331 B.C.) his Companion cavalry decided the day, and at the battle of the Hydaspes (326 B.C.) his cavalry so completely dislocated the Indian Army that his phalanx was able to disrupt it.

Cavalry as the Decisive Arm: 327 B.C.-Adrianople, A.D. 378.—From the days of Alexander onwards, cavalry, on account of their mobility, became the decisive arm. Hannibal's use of cavalry was superb, as the battles of the Trebbia (218 B.C.) and of Cannae (216 B.C.) testify. In both of these the Carthaginian cavalry completely dislocated the Roman legions by a rear attack. In the Roman armies the lack of good cavalry proved their ruin, and it was not until such a force was raised and trained by Scipio Africanus that the Carthaginians were eventually defeated at the battle of Ilipa (205 B.C.), and annihilated at that of Zama (202 B.C.). At Ilipa Scipio beat Hasdrubal by a double envelopment carried out by infantry and cavalry, and at Zama he smashed Hannibal by holding him in front with infantry and striking him in rear with cavalry.

During the days of Julius Caesar, the most serious defeat sustained by the Romans was that of Crassus at the hands of Surena, the Parthian general, whose entire force was composed of mounted archers and heavy cavalry. The Parthians, adopting an improved form of Scythian tactics, won a decisive victory; of the 40,000 Romans who crossed the Euphrates 20,000 were killed and 10,000 made prisoners. The Parthian success was due to the inability of the Romans to develop offensive power from a moving base. Their organization did not enable them to ward off shock and envelopment, while that of their enemy did permit of them enveloping and charging; for in this battle their heavy cavalry provided the necessary stability for the attack of their mounted bowmen and the distraction effected by this attack enabled the heavy cavalry of the Parthians to dislocate and disrupt the Roman legions.

From the battle of Pharsalus (48 B.C.) the legion learned for a space how to hold its own against cavalry, mainly by employing cavalry. Under Diocletian (A.D. 245–313) cavalry rose from one-tenth to one-third of the infantry, and numbered some 160,000; but this great mass of horse was withdrawn from the infantry, and by being formed into a frontier guard lost its offensive spirit. Meanwhile a steady decline took place in the infantry, mercenaries were enlisted, discipline was relaxed, pay increased and armour discarded because of its weight. Of the latter Vegetius wrote: ". . . to avoid fatigue, they allow themselves to be butchered shamefully like cattle." This separation of infantry and cavalry was the main tactical cause of the decline of Rome's military power. The unsupported Roman cavalry, trained as frontier police and for protective duties, were no match for the fierce barbarian horsemen who were now distracting the empire. From the first irruption of the Goths, in the year 248, the Roman cavalry were steadily increased until by the reign of Constantine (288–337) cavalry composed the principal part of the Roman armies; but all in vain. At Adrianople in 378, three Roman legions sent against the Visigoths were overwhelmed and practically annihilated. The Gothic horsemen, *having perfected a new-fangled stirrup*, rode and fought with a vigour and deadliness new to the mounted warrior. Caught massed under a blazing sun, the Roman flank was struck relentlessly by the Gothic horse, and again the dislocation of the Romans, which heralded their disruption, was effected by a cavalry rear attack. The Emperor Valens lost his life, and 40,000 legionnaires perished. From that day cavalry was to become the predominant arm for a thousand years, while the infantry deteriorated into a mere auxiliary.

Cavalry the Predominant Arm: Chalons, 451-Agincourt, 1415.—Fifty-two years after Adrianople, Roman arms at Tricameron won a decisive victory over the Vandals in Africa purely by cavalry. Belisarius had found so little use for his infantry that he mounted them to serve as dragoons. In Europe, however, the hardy and warlike barbarian tribes, fighting chiefly on horseback, soon flooded the Roman provinces. By 410 A.D., the Goths under Alaric captured Rome, and the "mistress of the world" was handed over to the licentious fury of the Huns. The barbarian advance culminated in the battle of Chalons (451) where Attila, after uniting Germany and Scythia, was met and defeated by Aetius and Theodoric. This was the last victory won by Imperial Rome in the West; the dark ages descended upon western Europe, and in the conduct of war that area entered the epoch of the iron-clad lancer.

From the days of Justinian (483–565) to those of the fourth Crusade, which resulted in the sack of Constantinople (1204), highly organized armies comprising well-equipped heavy and light cavalry were maintained by the Eastern empire. In the West, however, military art virtually disappeared, and as principalities took form and feudalism was established the common folk were virtually prohibited from taking part in the "noble" trade of war, which was carried on by raiding and pillaging barons. As the military caste of this period was based on wealth, and as western Europe was largely roadless, cavalry remained the predominant arm, and sought perfection not through improved tactics, or organization, but through armour. By the opening of the 9th century the old military organization of Rome had been replaced by comparatively small bands of mailed knights followed by a mob of retainers who pillaged the countryside and so acted as "administrative units." In England, in the Low Countries and in Switzerland, infantry were still maintained, but were so ill-equipped that when confronted by cavalry in open, or even semi-open, country they were forced to seek protection behind palisades, as was the case with the Saxons at Hastings (1066). Under Charlemagne the mail-clad knight was reaching his zenith, and, as is always the case when the peak of supremacy is topped, decline follows. To the knight of the middle ages the protective base of his offensive power was no longer afforded by the infantry mass, but by the armour he wore, his mobility being provided by his horse. As long as he was not met by equally well mounted and armoured antagonists this combination of mobility and protection proved tactically irresistible, yet seldom did it lead to profitable strategical results. But as soon as he was, it became neutralized, and with neutralization, tactics as an art utterly deteriorated and were replaced by mob fighting.

This self-contained protective power of cavalry is most noticeable during the Crusades, for in spite of the low discipline of the

Christian knights and their very rudimentary knowledge of tactics, normally their casualties were remarkably small. At the battle of Hazarth (1125), Baldwin lost only 24 men, while the Turkish losses amounted to 2,000; at Jaffa (1191) two Crusaders were killed on one side and 700 Turks on the other. The Crusaders, however, lost large numbers of horses, and as the rabble of beggars and vagrants who accompanied them were useless as infantry (further, the code of chivalry did not sanction their use), at times it became necessary for knights to fight on foot, or to abstain from fighting altogether. This involuntary change in tactics led to the Crusaders rediscovering the value of the protective infantry base as a mobile fortress from which the mounted knights could sally forth. In 1248, St. Louis of France adopted this change intentionally. Near Damietta he landed his knights and drew them up on foot in order of battle to cover his disembarkation. The interesting point to note in these operations is that the action of these knights foreshadowed the approaching revival of infantry: "They formed up in serried ranks, placed their bucklers upright in the sand before them, and resting their long lances on the top of their shields, presented an impenetrable array of steel points, before which the Muslim horse fell back in confusion." One of the military influences of the Crusades was the weakening of feudalism through the rise of a commercial class made rich by buying up the knights' lands. This class was concentrated in the cities, and as early as 1057 Pavia and Milan raised armies of their own, largely composed of infantry.

Another result of increasing prosperity was the reintroduction of plate armour, which though it rendered the knight on foot practically invulnerable to infantry attack, when mounted, more and more did it sacrifice his mobility to protection. This seriously influenced the value of the dismounted base, for armour had become so heavy that the dismounted knight was unable to move far on foot. At the battle of Tagliacozzo (1268), Conradin's Ghibelline knights were so heavily armoured that Charles of Anjou's cavalry, after having exhausted them by repeated charges, rolled them out of their saddles by seizing them by their shoulders.

With signs of cavalry power diminishing in the West, there appeared in the East the very essence of power by the mounted warrior. In the latter part of the 12th century there arose on the plains of Mongolia the most formidable cavalry warrior of human annals—Genghis Khan. Utilizing the horsemanship and spirit of conflict which permeated the character of his people, he created vast organized mounted hordes which swept the entire northern and eastern areas of Asia. It is alleged that a mounted force of 700,000 men, held together by a discipline of unyielding iron, rode to his will. Death was the penalty for turning back during action without an order or for neglecting to pick up equipment dropped by a front-file man. From a penetrating native perception, the Khan conceived the powers of co-ordinated and disciplined cavalry. Vigilant and ceaseless training perfected a standard for tactical measures. "A man of my bodyguard," Genghis Khan had announced, "is superior to a regimental commander of another division." The tactical skill of the Mongols had been developed in the stress of war. They had learned to keep track of an enemy's movements while concealing their own. In manoeuvre for battle they had learned not to depend on commands given by a voice which often cannot be heard in the uproar of moving mounted men. Regiments signalled their movements by raising black or white flags during the day and by a similar use of coloured lanterns at night. Other signals were given by the use of whistling arrows, which emitted sound through a hollow pierced head. They hid their formations at times behind a drifting smoke screen. The Mongol horde, unlike the Crusade, formed a movement of deadly intensity by virtue of its disciplined co-ordination and cohesion towards a common end. Followed by immense trains of wagons and great herds of cattle, they could exist for years off the country invaded. They crossed rivers on ice or in leathern boats. They fought mainly with arrows, avoiding close struggle, and strove to destroy their enemies from afar with projectile weapons. There was a fluidity and flexibility in their movements found wanting in the fixed, cumbersome ranks of European forces.

After the death of the great Khan, 150,000 Mongols under the able Sabutai, in 1235, marched towards the setting sun and threatened to flood the whole of Europe. In the next six years this enormous horde had marched one-fourth the distance around the globe. Sabutai swept through present day Russia and on to the plains of Hungary and Poland. Eastern Europe, from the Carpathians to the Baltic, fell under his domain. Although victorious in their fierce battle with the Poles at Wahlstall in April 1241, the strength of the invading Mongols had been so taxed that they turned back to the East. The leaders of western Europe learned little concerning the capacity of highly mobile cavalry in great numbers presented to them by the Mongolian mounted men.

Meanwhile, in western Europe progress in the construction of the bow and the crossbow was another reason for increasing the thickness of armour. At the siege of Abergavenny, in 1182, it is recorded that the Welsh arrows could penetrate an oak door four inches thick. No chain mail could withstand such a blow, consequently plate armour was worn over the mail shirt. As armour increased in weight natural obstacles began to play a decisive part on the battlefield. When ground could not be crossed on horseback it had to be crossed on foot, and the knight deprived of his horse lost much of his tactical value, consequently an able enemy sought every means in his power to compel him to dismount. One of these means was choice of ground, another, archery; for horse armour never proved satisfactory.

At the battle of Dupplin Muir (1332), Baliol and Beaumont did not beat the earl of Mar by reckless charges, but by skillful weapon co-operation. The majority of their knights were dismounted and formed into a phalanx, the flanks of which were protected by archers, while 40 mounted knights were kept in reserve. The earl of Mar charged the phalanx which remained unshaken; his knights, immobilized by the archers on the flanks, were routed by Baliol's mounted squadron. This battle is the birth of a new era in tactics—the tactics of bow, pike and lance combined. It formed the mould in which all the English operations of the Hundred Years' War were cast, a war which proved disastrous to the gallant but insubordinate French chivalry, as the battles of Crécy (1346), Poitiers (1356), and Agincourt (1415) testify. The cavalry difficulty throughout was the armouring of the horse. At Crécy (where gunpowder was first introduced) the horse proved the weak link in the French organization, for of the next great battle, namely Poitiers, John le Bel wrote of the French knights: "All fought on foot, through fear that, as at the battle of Crécy, the archers would kill their horses." Meanwhile in Switzerland infantry armed with pike and halberd, and fighting in phalangeal order, were taking toll of German and Austrian cavalry; and in Bohemia, Ziska by employing wagons in laager created movable fortresses known as the Wagenburg (wagon fort) against which his enemy's cavalry shattered themselves in vain. As wealth increased, mercenaries once again came to the fore, and being professional soldiers whose pay as well as whose lives depended on their art, tactics once again began to assume a coherent form, especially under the English commander-in-chief of Pope Urban V, Sir John Hawkwood, who may be considered the first great general of modern times. From the battle of Poitiers onwards cavalry fell into a rapid decline; the French knights learned nothing, and as the bow and pike destroyed them a new weapon arose in the crude bombards of the 14th century, which was destined to revolutionize the whole art of war, to reduce cavalry to the position they held in the days of the Scythians, and to advance infantry to the heyday of the Spartan phalanx. At the battle of Formigny (1450), three small culverins threw the English archers into disorder, and at Morat (1476) Charles the Bold of Burgundy was defeated by the Swiss who made good use of 6,000 hand guns.

Cavalry in the Age of Gunpowder.—For 1,000 years cavalry had sought to solve the problem of mobility through protection by armour. This being no longer possible, because armour could be penetrated by the bullet, after much trial and error a solution was sought through fire-power (the very cause of its obsolescence), that is to say, by combining cavalry with the other arms. In 1494, Charles VIII of France entered Rome, and in the words of Machiavelli: "He conquered Italy with a piece of chalk."

Arming a tenth of his infantry with the escopette, a species of arquebus, and accompanied by 140 heavy cannon and a number of small pieces, nothing could resist him, and so all he had to do was to chalk off areas on the map to which he wished to go, and there he went.

As armour grew lighter the knight exchanged his lance for the petronel, a type of hand cannon, in order to fire on infantry in place of charging them. This form of attack was first used by the French at the battle of Cerisoles, in 1544, and proved effective because the attack could be prolonged indefinitely, and against such organized Scythian tactics the infantry were powerless until the arquebus was improved, when cavalry became more immobile than ever. Soon the petronel was replaced by the arquebus-à-rouet, and a little later on by the wheel-lock pistol, which was first used by the German cavalry at the battle of St. Quentin, in 1557.

The lance now vanished, and attempts were made to develop cavalry mobility by mixing squadrons with infantry units. As early as the battle of Pavia (1525), the Marquis of Pescara had adopted this organization, and though in a clumsy way it linked fire-power and shock, the mobility of cavalry was so limited by the pace of the infantry that the cavalry attack was reduced to a walk. Twenty-five years after this battle, Marshal de Brissac mounted a number of his infantrymen on horseback, and the era of the modern Dragoon, or mounted infantryman, was initiated.

During the Thirty Years' War (1618–48) the employment of cavalry increased, cavalry mobility being sought not through their own fire power but through that of infantry, and especially artillery. Supported by artillery, Gustavus Adolphus' cavalry rode forward, fired their pistols and charged home with the sword. At Breitenfeld (1631) and at Lutzen (1632) his cavalry played the decisive part. In England he was emulated by Cromwell—the battle of Grantham (1643) was decided by the sword, so was Marston Moor (1644), and so was Naseby (1645). In France the reversion to shock tactics was no whit behind-hand: Turenne favoured the *arme blanche*, and issued instructions to his cavalry to use the sword alone. The impetuous Condé did likewise, and so also Marshal Luxembourg at Leuze, in 1691. In Germany, however, Montecuculi still favoured fire-arms for cavalry; he considered the lance useless, and looked upon the horses of his Dragoons solely as a means of conveyance.

This change is significant and cannot alone be attributed to the genius of such cavalry leaders as Pappenheim and Gustavus. The underlying reason for it is probably to be found in the universal adoption of the matchlock, and the consequent reduction of the pikemen. The matchlock was a slow-loading and unreliable weapon, especially in rainy weather when infantry are apt to be surprised in mist or fog. It was on such occasions as these that cavalry frequently proved themselves the decisive arm, up to the adoption of the percussion cap in 1839. A notable instance of this was the battle of Eylau (1807). During the 18th century the idea of the shock continued to grow. Marlborough used cavalry in mass. Blenheim (1704) was decided by cavalry, and so was Malplaquet (1708). In these battles are to be discovered the germ of the superb cavalry actions of Ziethen and Seydlitz, which characterized the Seven Years' War (1756–63). Charles XII of Sweden carried the shock to its extreme. He prohibited the use of armour, raced over Europe, rode to death two horses while reviewing a regiment, and met an impetuous end at Pultowa (1709). Marshal Saxe, in a reasoned degree, emulated him.

Under Frederick the Great, cavalry once again reached its zenith, and out of 22 of his battles at least 15 were won by the cavalry arm working in close co-operation with gun and musket. In his regulations for cavalry Frederick wrote: "They will move off at a fast trot and charge at the gallop, being careful to be well closed together. His Majesty will guarantee that the enemy will be beaten every time they are charged in this way." The exploits of Seydlitz and Ziethen proved that Frederick was not wrong. Rosbach (1757) was a great cavalry victory, and so, in a lesser degree, was Zorndorf (1758). The secret of Frederick's success lay not only in the artillery preparation which heralded the charge, nor in his system of attack, but in the training of his troopers.

The war of the American Revolution (1775–81) provides no example of outstanding cavalry work, nor do the French Revolutionary Wars, except for the brilliant charge of the English 15th Hussars at Villers-en-Couché (1794), where some 300 British and Austrian cavalry charged and routed 10,000 French infantry and cavalry, driving them into Cambrai with a loss of 1,200 men. The slowing down of the shock first became perceptible in Bonaparte's campaign in Egypt, when the world-famed Mameluke cavalry failed to make any real impression on his infantry squares. At Mount Tabor (1799) 6,000 French infantry under Kléber gained a decisive victory over 30,000 Turks and Mamelukes. From this battle onwards to the World War of 1914–18 the declining power of cavalry remains constant.

Napoleon relied on all arms, but particularly on fire power, and in spite of the many cavalry charges executed during his wars, his cavalry were pre-eminently a strategic force for observation and protection, and a tactical force for pursuit. With his strategic employment of cavalry, no commander was ever more completely informed at all times of the movements and composition of the hostile army than was Napoleon. His earlier manoeuvres, conceived after a careful synchronization of time and space factors, were made practical by skillfully led cavalry. Far-flung columns, well in advance of his main armies, not only kept him posted of hostile movements but were influential in manoeuvring an enemy into an area of Napoleon's own selection. Once contact was gained by main bodies, cavalry invariably were withdrawn to flanks or to the rear in reserve. While mounted charges were executed, they were made at that period in battle when the enemy was shattered by fire and the keen discernment of Napoleon foresaw conclusive results. From the flanks and rear his cavalry were able to deliver the decisive thrust or spring in pursuit of a routed enemy, which meant destruction rather than an orderly retirement and the ability to fight again after reconcentration and reorganization. At Eylau (1807) Napoleonic cavalry, encountering the Russian Cossacks, were confronted for the first time by a mobile element of their own quality; pursuit proved impossible, and strategic reconnaissance ineffective. In the Emperor's subsequent campaigns of 1812–13–14, superior enemy cavalry nullified any real fruits of victory, and in the retreat from Moscow were responsible mainly for the gradual disintegration of the Grand Army. The freedom of manoeuvre, the basis of Napoleon's success, had been reversed.

The Napoleonic wars were followed by 40 years of profound military coma. In 1823, Capt. John Norton, of the 34th English Regiment, invented the cylindro-conoidal bullet. He received no encouragement, for the duke of Wellington considered that the Brown Bess could not be bettered, yet Norton's bullet was the greatest military invention since the flint-lock. In 1853, Capt. Minié, of the French army, invented a similar projectile. In England, Sir William Napier opposed its adoption as he considered that it would destroy the infantry spirit by turning infantry into "long range assassins." It was, however, adopted; it had a range of 1,000yd., and it sealed the doom of the cavalry charge. The war in Crimea (1854–55) taught soldiers nothing new regarding cavalry except to emphasize its misuse by ill-informed commanders of combined arms and to demonstrate the gallantry and spirit of the arm. The battle of Balaclava gave to the world only the famed epic of "The Charge of the Light Brigade" and evidence of the courage, discipline and combative will to close with an enemy characteristic of the British mounted warrior. (*See* BALACLAVA.) (J. F. C. F.; J. K. H.; X.)

The Mounted Rifleman.—In the next war, the American Civil War (1861–65), a pronounced transition in cavalry tactics took form. The evolution of its tactics switched radically from the accepted European tenets of that day. The Confederate states, largely rural and agricultural, were able to create promptly a considerable cavalry to be used in strictly cavalry roles. The Union, largely of urban population, organized cavalry at a slower pace and employed it, initially, on the futile assignments of outpost, convoy, messenger and other associated activities. Employing cavalry in large units, Lee, in Virginia, was able to reap the benefit of decisive victories during the first two

years of the war; his own intentions were always screened from the enemy, while their movements and dispositions habitually were known to him. By May 1862, the Union, finally awake, assembled 10,000 horses into a cavalry corps. At Chancellorsville this formidable cavalry force was dispatched southward on a useless raid. Lee's cavalry, under James Stuart, discovering an open flank on the Union right, skilfully screened the movement of Thomas ("Stonewall") Jackson's corps, which launched a powerful surprise attack resulting in one of the most complete victories of Confederate arms. By 1863 cavalry tactics on both sides had become concerned principally with dismounted action and proved so effective that the mounted charge was a rarity thereafter. The eventual defeat of Lee was made possible in part through the able employment of a highly mobile cavalry and infantry force under Philip Sheridan. Repeated attacks against the Confederate lines of supply effected their dislocation by depriving them of a protected base. Increased powers of weapon fire had forced a new development of the cavalry dragoon or mounted rifleman—not to be confused with mounted infantry, which utilizes horses only as transportation and habitually fights dismounted; the mounted rifleman is trained and equipped to fight either dismounted or mounted. The revolver, introduced in this war, had proven a formidable cavalry weapon.

The wars which followed in Europe in 1866 and 1870 were marked by a complete disregard of the cavalry lessons learned from the American Civil War. The Austro-Prussian War (1866) saw 56,000 cavalrymen still armed with the lance and sabre charging in the face of the breech-loading needle gun and the Minié rifle. The Franco-German War (1870–71) saw 96,000 cavalry take the field similarly equipped. Their tactics called only for mounted action. French cavalry had learned nothing since Waterloo. The Germans were bold and pushful, using their cavalry strategically with considerable effect in order to cover their own movements while discovering those of the enemy. The massed charge was attempted. Jean A. Margueritte failed; Adalbert von Bredow succeeded, but at terrific cost. His was the last successful massed boot-to-boot cavalry charge in military history.

In South Africa (1899–1902) the Boers, accepting the lessons of the American Civil War, fought with large numbers of mounted riflemen who moved hither and yon, came and went, attacked and retired almost at will. The British faced this type of action initially with a force in which infantry predominated and included a few cavalry regiments armed with swords or lances and depending mainly on these weapons for combat. Not until British mounted elements were reorganized on a dragoon basis were the British able to conquer a people immeasurably their inferior in numbers and resources.

In the Russo-Japanese War (1904–05) cavalry action of little consequence occurred. The outstanding note was the absence of the lance and sword, which were nowhere seen. In combat, the rifle was supreme; any thought of reliance on the sword was banished. The few achievements of Russian cavalry in this war came through the effect of fire action. Little use was made of the cavalry masses of Alexei Kuropatkin organized and equipped on the European model of massed action. Japanese cavalry, with few exceptions, carried out their performances with the carbine and usually in close touch with their own infantry.

World War I.—During World War I, little use was made of the potential power of cavalry available to both sides. The limitations which the bullet placed on cavalry movement begot the trench; for had cavalry been able to move, the construction of entrenched fronts would have been all but impossible. On the western front, ten German cavalry divisions (approximately 70,000) faced ten French and one British cavalry divisions. The tool was there for the appearance of a master of the art of war capable of visualizing the power and capabilities of a numerous cavalry on missions of inspired and skillful design. There was need for mounted riflemen, not the European cavalry of that day relying principally on the sword and lance in mounted action. The French cavalry were split into useless detachments, and the only sizable force, under Sordet, was marched futilely over the whole of southern Belgium and northern France; his operations availed nothing. The single British cavalry division, operating collectively as a unit, rendered invaluable assistance to the main forces by employing ground fire to delay the German advance south of Mons until reorganization behind them was effected. While their grand plan conceived a powerful enveloping thrust southward through northwestern France, the Germans made little use of the potential power of their cavalry to aid that operation. The bulk of their mounted forces was scattered over the fronts of several field armies rather than assembled for a decisive effort.

On the eastern front, Russia produced initially 24 cavalry divisions (approximately 200,000 horsemen), but like the leaders of ancient Rome, the Russian commanders expended the potential power of this force by scattering it along an entire frontier. The armies of Alexander Samsonov and Paul Rennenkampf invaded East Prussia with forces totalling 400,000 combined arms to meet the most crushing defeat of the war at Tannenberg. The decisive victory of the Germans was made possible largely by the success of a single German cavalry division in delaying the army of Rennenkampf. Later, Russia increased its cavalry to 54 divisions; but with military leaders unable to cope with the requirements of massed co-ordination, this vast force accomplished little. It was, indeed, the indirect cause of breaking down the transportation system of the country by the requirements of forage.

Cavalry achievements in this war reached their highest plane in Palestine under Edmund Allenby, an outstanding commander of mobile troops. At Armageddon, Sept. 1918, Allenby faced a strong Turkish army with a superior force of combined arms including three cavalry divisions and bombardment aviation. Crushing the enemy right, he dispatched his cavalry, not against the hostile flank, but against the rear. Fleeing Turkish elements crowded into the ravines and defiles which characterized the terrain. Halted and confused by combat aviation, they were annihilated when struck by the charging cavalry columns. The lesson of Armageddon lay not so much in the prowess of ground mobility as in the example of the formidable power of such forces when supported by fire from the air—a dreadful warning of the devastating type of future war. The transcendent lesson from this war was an exemplification of the need of essential supporting fires for all cavalry action—again, fire power and movement.

Four years of stabilized warfare on the continent of Europe had contributed little to the concept of offensive manoeuvre predicated on fire power and movement. Industrial civilization had furnished new potentialities to the power of weapon fires by development of automatic arms and the co-ordinated concentrative effect of massed artillery. Advancement in automotive vehicles afforded new concepts in factors of time and space. Combat aviation gave new reaches to radii of action and means of fire support. Armoured divisions were developed between World Wars I and II which included all supporting arms needed in modern warfare; infantry, artillery, signal, engineers, etc. These divisions were organized for missions requiring independent action, using great mobility and fire power.

World War II.—From the earliest stages of World War II, there emerged military leaders who had developed as an art of war the co-ordinated employment of mass machines on the ground and in the air. The Germans had conceived the effective means of creating fire power from a moving base for the support of highly mobile combat elements through close tactical air support. They produced a fire effect so devastating as to dislocate all hostile defenses and permit freedom of movement for a mobile mass. Under this rain of fire from the air the newer heavy cavalry breached hostile positions by the power of shock. The lighter cavalry, with amazing powers of mobility, rushed forward through the breaches to spread fanlike in devastating attacks upon the nerve and supply centres in the rear. Once in the open the sustained drive of this new cavalry continued under the protective power of their own self-contained fire. Mobility reached great heights. Poland as a first-class power was crushed in the space of days. The highly publicized static defenses of the French Maginot line were passed, and the streamlined power of the German offensive quickly overran western Europe. There were few if any battles of mass tanks on the European continent up to this time but in Africa on the Libyan, with a wide expanse of terrain, a new theory

was developed. Armed forces fought each other with as many as 500 tanks employed on each side. Mobility, surprise and shock were the deciding factors.

In the summer of 1944 the Allied Powers invaded the Normandy coast and launched a successful attack by a team of combined arms with each arm playing its major role. There were infantry, armoured divisions, separate tank battalions, all supported by tactical and strategic air. The operation began with one of the largest air-support missions of the entire war; 2,500 supporting aircraft flew over St. Lô, Fr., to saturate an area 6,000 yd. wide by 3,000 yd. deep. This was followed by close fighter support over advancing armoured columns. In this operation, the infantry divisions, with separate tank battalions in support, made the initial hole in the German lines and held the shoulders of the penetration, while the armoured divisions, using their speed, shock and mobility, splintered the enemy defenses and drove more than 400 mi. into the rear of the enemy's lines. Six weeks later the Allied armies, stopped by a lack of supplies, were at the German border.

Sixteen U.S. armoured divisions successfully applied the principles of fire, movement and shock action to help defeat the axis in World War II. Under Gen. George S. Patton, Jr., many of these units fought their way from Normandy to the Rhine and the Danube, overcoming the last of the famed German panzers in the west. At the same time other elements were pushing up the rugged Italian peninsula and through southeastern France to join their comrades beyond the Alps. With them in this effort were separate mechanized cavalry units which had been designed and equipped primarily for reconnaissance missions, and a large number of separate tank battalions. The reconnaissance units were called upon to perform a great variety of combat missions and spent only a small part of their time on reconnaissance.

It was generally acknowledged after World War II that the tank had become the decisive weapon of the ground force combat team. Military leaders recognized the strategic and tactical importance of armour and its characteristic mobility, massed fire power and terrific shock action.

CAVAN, one of the three counties of the old province of Ulster which are part of the Republic of Ireland. It is bounded north by Fermanagh and Monaghan, east by Monaghan and Meath, south by Meath, Westmeath and Longford and west by Longford and Leitrim. Pop. (1951) 66,377. Area 730 sq.mi.

In the northwest, County Cavan is occupied by hills of Millstone Grit, forming a wild country of mountains and bogs and rising to 2,188 ft. in the Cuilcagh. There occurs the Shannon Pot, source of the Shannon river. Farther east, approaching the county town of the same name, there is an extensive low-lying area of drift-covered Carboniferous limestone, resulting in undulating land. This region is one of the classic examples of drumlin topography, the innumerable low boulder-clay hills giving rise to a most complex drainage pattern consisting of a multiplicity of lakes known as Lough Oughter. The drainage system centres finally on the river Erne, which bisects the county from south to north. Many other lakes are scattered over the county, the largest being Lough Gowna, Lough Sheelin and Lough Ramor, all on or near the southern boundary. The eastern part of the county is developed on Silurian and Ordovician rocks, while near Kingscourt, in the extreme east, occurs an outlier of Triassic beds, downfaulted among the older Palaeozoics. Extensive deposits of gypsum have been located in this Triassic outlier, and an important manufacture of plaster and wallboard, capable of supplying all Irish needs and providing an export trade also, was developed after World War II.

The soil is generally a stiff clay, cold and watery, but capable of much improvement by drainage. In those districts not well adapted for tillage, the ground is peculiarly favourable for trees. The woods were at one time considerable, and the timber found in the bogs is of large dimensions. The farms are generally small, though in the higher lands there are larger grazing farms. Oats and potatoes are the principal crops; cattle rearing is the main occupation of the people. Flax, once of some importance, is almost neglected. The bleaching of linen and the distillation of whisky are both carried on to a small extent.

The town of Cavan was for centuries the seat of the O'Reillys, rulers of East Breifne (the western part of the county). In 1579 Cavan was made shire ground as part of Connaught, and in 1584 it was formed into a county of Ulster.

Some few remains of antiquity exist in the shape of cairns, raths and the ruins of small castles, chief among the latter being the 13th-century O'Reilly fortress, Cloughoughter castle, which stands on an island (an ancient crannog) of Lough Oughter. It was taken by the Cromwellians in 1653 and has been in ruin ever since. Three miles from the town of Cavan is Kilmore, which has a Protestant cathedral (1858–60) containing a Romanesque doorway brought from the abbey of Trinity Island in Lough Oughter. The see of Kilmore or Tir Briuin (Breffni) dates from before 1136, but in 1839 Ardagh was added to it and in 1841 Elphin was united to Kilmore and Ardagh to form the see of Kilmore and Elphin and Ardagh. The seat of the Roman Catholic bishop of Kilmore is at Cavan. County Cavan returns four members to the *dail eireann*. (D. G.)

CAVAN, an urban district and county town of County Cavan, Ire., 85½ mi. N.W. of Dublin by railway. Pop. (1951) 3,555. A Franciscan friary, founded in 1300 by Giolla O'Reilly, formerly existed there and was the burial place of O'Reilly of Breifne (d. 1491) and of Owen Roe O'Neill (d. 1649). On Tullymongan hill was the principal residence of the O'Reillys. The town was burned in 1690 by the Enniskilleners under Wolseley when they defeated James II's troops under the duke of Berwick. The town has some linen trade. It is the seat of the Roman Catholic diocese of Kilmore, which includes parts of counties Leitrim, Fermanagh, Meath and Sligo, and its modern Romanesque cathedral was completed in 1941.

CAVANILLES, ANTONIO JOSÉ (1745–1804), Spanish botanist, was born in Valencia on Jan. 16, 1745. In 1801 he became director of the botanic gardens at Madrid, where he died on May 4, 1804. In 1785–86 he published *Monadelphiae Classis Dissertationes X*, and in 1791 he began to issue *Icones et descriptiones plantarum Hispaniae*.

CAVATINA, originally a short song of simple character, without a second strain or any repetition of the air. It is now frequently applied to a simple melodious air, as distinguished from a brilliant aria, recitative, etc.

CAVAZZOLA (CAVAZZUOLA), the usual appellation of PAOLO MORANDO (*c.* 1486–1522), Italian painter. He was first trained under Francesco Morone, but his first dated work, the "Madonna Cagnola" (1508; Villa Gazzada near Varese), shows the Venetian characteristics acquired from his more notable master, F. Bonsignori; these were fully developed in his "Madonna" of 1514 (Berlin). Later, he was influenced by Raphael.

FAMOUS CAVES THROUGHOUT THE WORLD

1. The Giants' hall. Carlsbad Caverns, national park, New Mexico. Series of connected caverns, probably largest in world
2. Great Onyx cave, near Mammoth cave, Kentucky
3. Carlsbad cave, national monument, New Mexico. The king's throne room
4. Caverns of Luray, Virginia, Leidy column, in the blanket room
5. Shenandoah caverns, Virginia. "The Castle of Cardross"
6. Caverns of Luray, Virginia. Helen's Shawl
7. Black Hills, South Dakota. Wind cave
8. Syracuse, Sicily. The Ear of Dionysius
9. Indian Chamber cave, Jenolan, N.S.W., Australia. The Orient cave

culation does not fit the cave pattern. Such caves must be older than the hills and valleys of the region and are therefore judged to be products of the second method of origin.

A limestone or dolomite cave therefore is, or once was, a subterranean water course, its length far greater than its width or height. During a large part of its development it functioned like a pipe line, the flow occurring under hydrostatic conditions. After lowering of the water table, the cave became more like a roofed valley, with a free surface stream on its floor for a time, perhaps to the present.

Secondary Deposits.—Most enterable caves have ceased to grow larger; instead, they are suffering decrease in size from the secondary deposition of calcium carbonate in the form of travertine and stalagmites on the floor, draperies and curtains on the walls, and stalactites on the ceiling. The deposited material has been obtained from the roof rock by downward percolating rain water since air came to occupy the cave. To these secondary growths caves owe much of their beauty and most of their interest to the average visitor. Forms of the deposits are extraordinarily varied, chiefly in vertical dimensions, and fancy sees in them an almost unbelievable range of resemblances to forms already in the beholder's experience. The usual pure white of the calcium carbonate may be mottled and shaded with delicate hues of red, yellow and gray. Translucency may characterize some of the deposits and lend added charm.

Primitive Shelter.—Primitive man in all lands has utilized the natural shelter provided by caves, the rock shelter type having been his favourite. His tools, weapons, ornaments, hearths, the bones of his kills, even his wall pictographs and paintings have provided archaeologists with so much information that "cave man" has become a popular term for our early ancestors (*see* ARCHAEOLOGY: *Old World Archaeology*). Ice Age (Pleistocene) extinct carnivores—cave bear, cave lion, cave hyena—also used available caves south of the ice sheets of Europe and North America as refuges and dens, their remains being preserved in earthy floor deposits and beneath secondary floors of travertine.

Romance of Caves.—Legends and written history include many stories involving caves as heroes' refuges, robbers' dens, savages' holdouts, hiding places for conspirators or patriots or persecuted religious groups.

Every country in the world has commercialized caves, opened, lighted, paved where necessary and provided with stairways, bridges and even elevators for the convenience of sightseers. The lure of underground exploration of "wild caves" has produced many groups of amateur speleologists, popularly called spelunkers. (*See* also articles on various caves, such as COLOSSAL CAVERN; FINGAL'S CAVE; JACOBS' CAVERN; KENT'S CAVERN; LURAY CAVERN; MAMMOTH CAVE; POSTOJNA; WYANDOTTE CAVE; etc.)

Bretz, "Vadose and Phreatic Features of Limestone Caverns," *Journal of Geology*, vol. l, pp. 675–871 (1942); W. M. McGill, *Caverns of Virginia*, bulletin 35. Virginia Geological Survey (1935); R. W. Stone, *Pennsylvania Caves*, bulletin G3, Pennsylvania Geological Survey (Harrisburg, Pa., 1932); W. E. Davies, *Caverns of West Virginia*, vol. xix, West Virginia Geological Survey (1949). (J. H. Bz.)

CAVEA, a term applied to the rows of spectators' seats in Greek and Roman theatres and in Roman amphitheatres; also, less commonly, to the cells for wild beasts underneath the arena.

CAVEAT, in law, a notice given by the party interested (caveator) to the proper officer of a court of justice to prevent the taking of a certain step without warning. It is entered in connection with dealings in land registered in the land registry, with the grant of marriage licences, to prevent the issuing of a lunacy commission, to stay the probate of a will, letters of administration, etc. "Caveat" is also a term used in United States patent law (*see* PATENTS).

CAVEAT EMPTOR, a Latin phrase meaning literally "Let the buyer beware." It represents a legal rule in the purchase and sale of personal property that the buyer purchases at his own risk in the absence of an express warranty, or unless the law implies a seller's warranty, or there is found to have been fraud in the transaction. (*See* SALE OF GOODS.)

CAVELL, EDITH LOUISA (1865–1915), British nurse, was born Dec. 4, 1865, at Swardeston, Norfolk. She entered the London hospital as a probationer in 1895. In 1907 she was appointed the first matron of the Berkendael Medical institute, Brussels, which became a Red Cross hospital on the outbreak of World War I. From November 1914 to July 1915 wounded and derelict English and French soldiers were hidden from the Germans by Prince Reginald de Croy at his château near Mons, thence conveyed to the houses of Edith Cavell and others in Brussels, and furnished by them with money to reach the Dutch frontier, with the aid of guides obtained through Philippe Baucq. On Aug. 5, 1915, Edith Cavell was arrested and imprisoned. She admitted having sheltered and helped to convey to the frontier about 200 English, French and Belgians. A court-martial was held (Oct. 7 and 8), and a Belgian lawyer, Sadi Kirschen, defended Edith Cavell. On Oct. 9 she and Philippe Baucq were sentenced to death with three others who were afterward reprieved. Despite efforts to obtain a reprieve in which Brand Whitlock, the U.S. minister at Brussels, was active, Miss Cavell and Baucq were shot on Oct. 12. Miss Cavell, who had tended many wounded German soldiers with devoted care, faced the firing squad with a dignity which moved the world. To the British chaplain who administered a final sacrament, she made the remark, "Patriotism is not enough," which at once became as historic as Nelson's utterance at Trafalgar. On May 15, 1919, her body was removed to Norwich cathedral, after a memorial service in Westminster abbey. A memorial statue stands opposite the National Portrait gallery, London.

CAVENDISH, GEORGE (1500–1562?), the biographer of Cardinal Wolsey, was the elder son of Thomas Cavendish, clerk of the pipe in the exchequer. About 1527 he entered the service of Cardinal Wolsey as a gentleman-usher, and for the next three years he was in the closest personal attendance on the great man. It is plain that he enjoyed Wolsey's closest confidence to the end, for after the cardinal's death George Cavendish was called before the privy council and closely examined as to Wolsey's latest acts and words. Many years passed before his biography was composed. At length, in 1557, he wrote it out in its final form. It was impossible to publish it in the author's lifetime, but it was widely circulated in manuscript. The book was first printed in 1641 in a garbled text under the title of *The Negotiations of Thomas Wolsey.* The genuine text, from contemporary manuscripts, was first published in 1810. Until that time it was believed that the book was the composition of George Cavendish's younger brother William, the founder of Chatsworth, who also was attached to Wolsey; but Joseph Hunter, in a tract called *Who Wrote Cavendish's Life of Wolsey?* (1814), proved the claim of George. The book is the sole authentic record of a multitude of events highly important in a particularly interesting section of the history of England. Its biographical excellence was first emphasized by Bishop Mandell Creighton, who insisted that Cavendish was the earliest of the great English biographers and an individual writer of particular charm and originality.

See the edition of the *Life* published by S. W. Singer in 1815, which was reprinted, with a biographical introduction, by Henry Morley in the Universal Library Series (1885). *See* also Francis Bickley, *The Cavendish Family* (1911).

CAVENDISH, HENRY (1731–1810), English chemist and physicist, elder son of Lord Charles Cavendish, brother of the 3rd duke of Devonshire, and Lady Anne Grey, daughter of the duke of Kent, was born at Nice on Oct. 10, 1731. He was sent to school at Hackney in 1742, and in 1749 entered Peterhouse, Cambridge, which he left in 1753 without taking a degree. He appears to have spent some time in Paris with his brother Frederick during the following years, and apparently occupied himself in the study of mathematics and physics. Until he was about 40 he seems to have enjoyed a moderate allowance from his father

In his earlier pictures the figures are frontal and rather flat; later they are turned a little and more definitely modelled. His works can be identified by vivid, hard colour, a strong interest in small birds and other naturalistic details, over-careful drawing of eyes and the depiction of a finger of one hand in a pointing gesture. These features can be seen in the "Isabella d'Este" (*c.* 1514), apparently the only surviving painted likeness of the great noblewoman. Cavazzola's other works include the "Passion" polyptych, finished in 1517 (Verona); "St. Roch" (left wing of an altarpiece, 1518) and "Virgin and Child," both in the National gallery, London; and his last dated work, the "Vision of the Madonna" altarpiece (1522, Verona). According to G. Vasari, in aspiring to greatness he undermined his health. He worked mainly in his native Verona, dying there on Aug. 13, 1522.

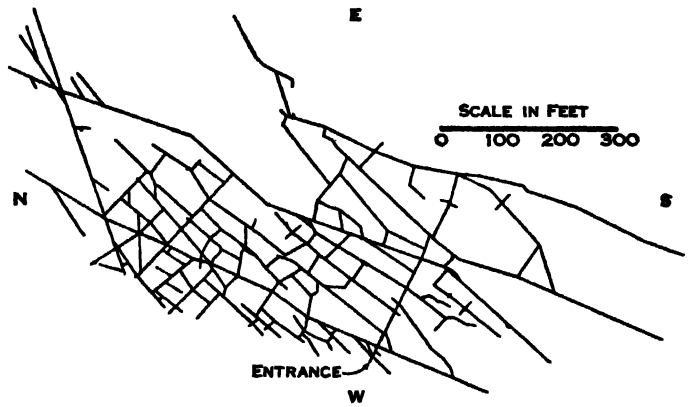
See A. Alcardi, *Paulo Morando* (Verona, 1853).

CAVE, EDWARD (1691–1754), English printer, was born at Newton, Warwickshire, Feb. 27, 1691, and died Jan. 10, 1754. He entered the grammar school at Rugby, where his father was a cobbler, but was involved in pranks which cost him the headmaster's favour and the hope of proceeding to the university. After many vicissitudes he became apprentice to a London printer and was sent to Norwich to conduct a printing house and weekly paper. While engaged in printing and journalism, he obtained employment in the post office (1723) and presently a clerkship of franks, retiring only in 1745. He meanwhile undertook the exchange of news between London and provincial papers. In 1728 he was implicated with others in a charge of breach of privilege. In 1731 he bought a printing house and set up a press at St. John's Gate, Clerkenwell, and launched the *Gentleman's Magazine* (*see* PERIODICAL), of which he remained proprietor during his lifetime, editing it under the pseudonym of Sylvanus Urban, Gent. This, the first magazine, offered extracts and abridgments from the contemporary press, "with some other matters of Use or Amusement that will be communicated to us." In 1732 he began to issue from surreptitious and often scanty reports accounts of the debates in both houses of parliament, and in 1738 was censured for printing the king's answer to an address before it had been announced by the speaker. Thenceforth the debates appeared as those of the "senate of Great Lilliput." In 1747 he was reprimanded for publishing an account of the trial of Lord Lovat and discontinued the reports, beginning afresh with brief accounts of transactions in parliament in 1752.

From Cave Samuel Johnson got his earliest regular literary employment, on these debates and in other writing and editing. Cave was, moreover, concerned in the publication of several of Johnson's works besides those which appeared (in whole or in part) in the magazine: notably, *London*, the *Life of Savage*, *Irene* and the *Rambler*. On his death, Johnson wrote a sympathetic obituary notice.

See John Nichols, *Literary Anecdotes of the Eighteenth Century*, vol. v (London, 1812) and *Introduction to General Index of the Gentleman's Magazine* (London, 1821); C. L. Carson, *The First Magazine* (Providence, R.I., 1938); B. B. Hoover, *Samuel Johnson's Parliamentary Reporting* (Berkeley, Calif., 1953). (M. M. Ls.)

CAVE, a cavity in rock large enough for human entrance and traverse. Cavern is nearly synonymous, but generally means a large cave or a large connected group of caves. A rock shelter is a cave whose mouth is the largest cross section of the cavity and whose roof has adequate projection out over the floor. Collapse of part of the cave roof to make a hole completely through to the surface constitutes one common type of sinkhole, a cave without a roof.



Origin.—Caves may originate with the making of the rock which encloses them or they may be secondary to the rock making. To the first group belong caves in congealed lava flows, made generally by freezing of the surface of the lava stream while the deeper portion remains liquid and continues to flow. Failure of supply under these conditions may allow the fluid lava to drain out and leave a linear hollow tube perhaps tens of feet in diameter.

Most caves belong to the second group, having been made by removal of material after the enclosing rock was made. Some of these occur along exposed coasts where mechanical erosion occurs under vigorous wave attack. These sea caves are not limited to any particular kind of rock and they lack marked linearity and subterranean extent. Rock shelters commonly are the result of crumbling and falling away of weak rock on a hillside beneath stronger rock which forms the roof.

Limestone and Dolomite Caves.—These rocks contain the largest caves and the largest number of caves of the earth's surface. They are all secondary, having been made by the solvent action of circulating ground water. These calcareous rocks, slightly soluble in pure water, are more rapidly attacked if the water has brought organic acid or carbon dioxide down from the surface in it. The circulation occurs chiefly along the usually horizontal bedding planes and the commonly vertical joint cracks, the water moving under gravity to lower levels and to eventual escape as springs and seepages. The sides of these primitive passages are attacked and the dissolved material removed, thus enlargement results. From perhaps a multitude of such early water routes, integration of the subterranean water system proceeds by greater enlargement of more favourably located routes and abandonment of less favoured ones.

Limestone and dolomite caves have been discovered in well drillings below the water table (upper level of saturated rock) and therefore completely filled with water. Some caves are enterable in dry weather only, being completely filled during the rainy seasons. Many are traversable at all times, although they carry perennial streams on their floors. Some lack streams entirely, but possess shapes and wall sculptures that indubitably are of solutional origin.

The question therefore arises as to whether caves in calcareous rock (1) have been made in large measure by solutional and abrasional stream work on the floor while only air occupied the upper part of the cave, and thus have been deepened and perhaps widened in the manner by which surface streams enlarge

PLAN OF MARK TWAIN CAVE, HANNIBAL, MO.

An outstanding example of a cave system in which the ground plan was determined entirely by vertical joints and in which development occurred almost wholly below an earlier, higher water table

their valleys or (2) have been made at some earlier time when the water table was higher in the rock, the cave being completely filled at the time. Lowering of the water table occurs in any region as the surface streams deepen their valleys and thus provide lower exits for seepages and springs. Thus, by this second view, enterable limestone and dolomite caves, with streams on their floors, are going through a second episode in their development. They are still water routes, but their enlargement now is occurring only in the basal portions.

The many caves possessing solutional shapes on their ceilings seem to require, for their origin, a tube-full flow, like that of a water main. The ground plan of many caves suggests the street system of a city, a multitude of narrow, linear, intersecting passages having been developed along two or more sets of nearly vertical joints in the rock. This lack of integration into one main water course with tributary courses argues strongly for origin in the saturated zone below the water table.

There are many horizontally extended caves under hills whose catch of rainfall never could have provided the ground-water flow recorded and whose directional control of any ground-water cir-

culation does not fit the cave pattern. Such caves must be older than the hills and valleys of the region and are therefore judged to be products of the second method of origin.

A limestone or dolomite cave therefore is, or once was, a subterranean water course, its length far greater than its width or height. During a large part of its development it functioned like a pipe line, the flow occurring under hydrostatic conditions. After lowering of the water table, the cave became more like a roofed valley, with a free surface stream on its floor for a time, perhaps to the present.

Secondary Deposits.—Most enterable caves have ceased to grow larger; instead, they are suffering decrease in size from the secondary deposition of calcium carbonate in the form of travertine and stalagmites on the floor, draperies and curtains on the walls, and stalactites on the ceiling. The deposited material has been obtained from the roof rock by downward percolating rain water since air came to occupy the cave. To these secondary growths caves owe much of their beauty and most of their interest to the average visitor. Forms of the deposits are extraordinarily varied, chiefly in vertical dimensions, and fancy sees in them an almost unbelievable range of resemblances to forms already in the beholder's experience. The usual pure white of the calcium carbonate may be mottled and shaded with delicate hues of red, yellow and gray. Translucency may characterize some of the deposits and lend added charm.

Primitive Shelter.—Primitive man in all lands has utilized the natural shelter provided by caves, the rock shelter type having been his favourite. His tools, weapons, ornaments, hearths, the bones of his kills, even his wall pictographs and paintings have provided archaeologists with so much information that "cave man" has become a popular term for our early ancestors (*see* ARCHAEOLOGY: *Old World Archaeology*). Ice Age (Pleistocene) extinct carnivores—cave bear, cave lion, cave hyena—also used available caves south of the ice sheets of Europe and North America as refuges and dens, their remains being preserved in earthy floor deposits and beneath secondary floors of travertine.

CAVENDISH, HENRY (1731–1810), English chemist and physicist, elder son of Lord Charles Cavendish, brother of the 3rd duke of Devonshire, and Lady Anne Grey, daughter of the duke of Kent, was born at Nice on Oct. 10, 1731. He was sent to school at Hackney in 1742, and in 1749 entered Peterhouse, Cambridge, which he left in 1753 without taking a degree. He appears to have spent some time in Paris with his brother Frederick during the following years, and apparently occupied himself in the study of mathematics and physics. Until he was about 40 he seems to have enjoyed a moderate allowance from his father

(d. 1783), but in the latter part of his life an aunt left him a fortune which, together with his patrimony, made him one of the richest men of his time. It was commonly said that he was the richest of the philosophers and the most philosophical of the rich.

Cavendish lived principally at Clapham Common, but he had also a town house in Bloomsbury which is now marked with a tablet. His library was in a house in Dean street, Soho; and there he used to attend on appointed days to lend books to men who were properly vouched for. He was a regular attendant at the meetings of the Royal society, of which he became a fellow in 1760, and he dined every Thursday with the club composed of its members. Otherwise, he had little intercourse with society; indeed, his chief object in life seems to have been to avoid the attention of his fellows. With his relatives he had little communication, and even Lord George Cavendish, his second cousin, whom he made his principal heir, he saw only for a few minutes once a year. His dinner was ordered daily by a note placed on the hall table, and his women servants were instructed to keep out of his sight on pain of dismissal. In person he was tall and rather thin; his dress was old-fashioned and singularly uniform, and was inclined to be shabby about the times when the precisely arranged visits of his tailor were due. He had a slight hesitation in his speech, and his air of timidity and reserve was almost ludicrous. He never married. He died at Clapham on Feb. 24, 1810, leaving funded property worth £700,000, and a landed estate of £8,000 a year, together with canal and other property, and £50,000 at his bankers'. He was buried in the family vault at All Saints' church, Derby. In 1927 this church became the cathedral church of the new diocese of Derby, and it was decided to erect a monument there to Henry Cavendish.

Cavendish's scientific work was wide in its range. He took for his motto, "Everything is ordered by measure, number and weight." The papers he himself published form an incomplete record of his researches, since many of the results he obtained became generally known only years after his death; yet the Institute of France in 1803 chose him as one of its eight foreign associates. His first communication to the Royal society, a chemical paper on "Factitious Airs" (*Philosophical Transactions*, 1766), consisted of three parts, a fourth part remaining unpublished until 1839, when it was communicated to the British association by Canon W. Vernon Harcourt. This paper dealt mostly with "inflammable air" (hydrogen), which he was the first to recognize as a distinct substance, and "fixed air" (carbon dioxide). He determined the specific gravity of these gases with reference to common air, investigated the extent to which they are absorbed by various liquids and noted that the air produced by fermentation and putrefaction has properties identical with those of fixed air obtained from marble. He introduced new refinements into his experiments, such as the use of drying agents and the correction of the volume of a gas for temperature and pressure. In the following year he published a paper on the analysis of one of the London pump waters (from Rathbone place, Oxford street), which is closely connected with the memoirs referred to above, since it shows that the calcareous matter in that water is held in solution by the "fixed air" present and can be precipitated by lime. In 1783 he described observations he had made to determine whether or not the atmosphere is constant in composition; after testing the air on nearly 60 different days in 1781 he could find, after 400 determinations in the proportion of oxygen, no difference of which he could be sure, nor could he detect any sensible variation at different places. Two papers on "Experiments on Air," printed in the *Philosophical Transactions* for 1784 and 1785, contain his great discoveries of the compound nature of water and the composition of nitric acid. Starting from an experiment, narrated by Joseph Priestley, in which John Warltire fired a mixture of common air and hydrogen by electricity, with the result that there was a diminution of volume and a deposition of moisture, Cavendish burned about two parts of hydrogen with five of common air and noticed that the only liquid product was water. In another experiment he fired by electric spark a mixture of hydrogen and oxygen in a glass globe, similar to the apparatus now called "Cavendish's eudiometer," and again obtained water. Proceeding with these experiments he found that the resulting water contained nitric acid. In the second of the two papers he gives an account of the methods by which the composition of nitric acid was discovered. He observed also that a small fraction, about $\frac{1}{120}$, of the "phlogisticated air" of the atmosphere differed from the rest. In this residue he doubtless had a sample of the inert gas argon, which was only recognized as a distinct entity more than 100 years later by J. W. Rayleigh and Sir William Ramsay (*qq.v.*). In the meantime, many able chemists, including such masters as J. L. Gay-Lussac and R. W. von Bunsen, had made "complete" analyses of atmospheric air. It may be noted that, while Cavendish adhered to the phlogistic doctrine, he did not hold it with anything like the tenacity that characterized Priestley. Thus, in his 1784 paper on "Experiments on Air," he remarks that not only the experiments he is describing but also "most other phenomena of nature seem explicable as well, or nearly as well," upon the Lavoisierian view; but he did not accept it and continued to use the language of the phlogistic theory. Experiments on arsenic, published for the first time in 1921, showed that Cavendish had investigated the properties of arsenic acid about ten years before K. W. Scheele. He showed that arsenic oxide contained less phlogiston (*i.e.*, more oxygen) than arsenious oxide, which in turn contained less than free arsenic.

Cavendish's work on electricity, with the exception of two papers containing relatively unimportant matter, remained in the possession of the Devonshire family until 1879, when the papers were edited by James Clerk Maxwell as the *Electrical Researches of the Hon. Henry Cavendish*. This work shows that Cavendish had anticipated the researches of C. A. Coulomb, Michael Faraday and others. He investigated the capacity of condensers and constructed a series of condensers with which he measured the capacity of various pieces of apparatus using the "inch of electricity" as the unit of capacity. He discovered specific inductive capacity and measured this quantity; he showed that electric charges are confined to the surface of a conductor and that the inverse square law of force between charges holds to within 2%. Cavendish introduced the idea of potential under the name of "degree of electrification" in a paper published in 1771 under the title "Attempt to Explain Some of the Principal Phenomena of Electricity by Means of an Elastic Fluid." He investigated the power of different substances to conduct electrostatic discharges (*Phil. Trans.*, 1775) and completed an inquiry which amounted to an anticipation of Ohm's law.

Cavendish took up the study of heat, and had he published his results promptly he might have anticipated Joseph Black (*q.v.*) as the discoverer of latent heat and of specific heat. He published a paper on the freezing point of mercury in 1783, and in this paper he expressed doubt of the fluid theory of heat. He regarded heat as a manifestation of internal motion of the smallest particles, whereas Black considered it to be material in nature.

Cavendish's last great achievement was his series of experiments to determine the destiny of the earth (*Phil. Trans.*, 1798). The apparatus he employed was devised by John Michell, though Cavendish had the most important parts reconstructed to his own designs. The figure he gives for the specific gravity of the earth is 5.48, but in fact the mean of the 29 results he records works out at 5.448. Other publications of his later years dealt with the height of an aurora seen in 1784 (*Phil. Trans.*, 1790), the civil year of the Hindus (*ibid.*, 1792), and an improved method of graduating astronomical instruments (*ibid.*, 1809). Cavendish also had a taste for geology and made several tours in England for the purpose of gratifying it.

A *Life* by George Wilson (1818–59), printed for the Cavendish society in 1851, contains an account of his writings, both published and unpublished, together with a critical inquiry into the claims of all the alleged discoverers of the composition of water. Some of his instruments are preserved in the Royal institution, London, and his name is commemorated in the Cavendish Physical laboratory at Cambridge, which was built by the 7th duke of Devonshire.

The remainder of Cavendish's papers was placed at the disposition of the Royal society by the duke of Devonshire. In 1921 the previously published work, together with a number of unpublished experiments, appeared under the title *The Scientific Papers of the Honourable Henry Cavendish, F.R.S.; Vol. I, The Electrical Researches*, revised with preface and notes by Sir J. Larmor; *Vol. II, Chemical and Dynamical*, edited by Sir Thomas Edward Thorpe, with additions by Charles Chree and others.

CAVENDISH or CANDISH, **THOMAS** (1555?–1592), the third circumnavigator of the globe, was born in Trimley St. Martin, Suffolk, and educated at Corpus Christi college, Cambridge. In 1585 he accompanied Sir Richard Grenville to America. Soon returning to England, he undertook an elaborate imitation of Drake's great voyage. On July 21, 1586, he sailed from Plymouth with 123 men in three vessels, only one of which (the "Desire," of 140 tons) returned. By way of Sierra Leone, the Cape Verde Islands and Cabo Frio in Brazil, he coasted down to Patagonia (where he discovered "Port Desire," his only important contribution to knowledge), and passing through the Straits of Magellan fell upon the Spanish settlements and shipping on the west coast of South and Central America and of Mexico. Among his captures was the treasure galleon the "Great St. Anne," which he seized off Cape St. Lucas, the southern extremity of California (Nov. 14, 1587). After this success he struck across the Pacific for home, touching at the Ladrones, Philippines, Moluccas and

Java. He rounded the Cape of Good Hope, and arrived at Plymouth on Sept. 9–10, 1588, having circumnavigated the globe in two years and 50 days. It is said that his sailors were clothed in silk, his sails were damask and his topmast covered with cloth of gold. Yet by 1591 he was again in difficulties, and planned a fresh American and Pacific venture. John Davis (*q.v.*) accompanied him, but the voyage (undertaken with five vessels) was an utter failure. He died and was buried at sea, on the way home, May 20, 1592.

CAVENDISH, SIR WILLIAM (*c.* 1505–1557), founder of the English noble house of Cavendish, was the younger brother of George Cavendish (*q.v.*). His father, Thomas, was a descendant of Sir John Cavendish, the judge, who in 1381 was murdered by Jack Straw's insurgent peasants at Bury St. Edmunds. Of William's education nothing seems known, but in 1530 he was appointed one of the commissioners for visiting monasteries; he worked directly under Thomas Cromwell, whom he calls "master," and to whom many of his extant letters are addressed. In 1541 he was auditor of the court of augmentations, in 1546 treasurer of the king's chamber, and was knighted and sworn of the privy council. Under Edward VI and Mary he continued in favour at court; during the latter's reign he partially conformed, but on the occasion of the war with France he with other Derbyshire gentlemen refused the loan of £100 demanded by the queen. He died in 1557. Cavendish acquired large properties from the spoils of the monasteries, but in accordance with the wish of his third wife, Elizabeth, he sold them to purchase land in Derbyshire. This wife was the celebrated "building Bess of Hardwick," daughter of John Hardwicke of Hardwicke, Derbyshire; she completed the original building of Chatsworth house,—begun in 1553 by her husband,—of which nothing now remains. Her fourth husband was George Talbot, 6th earl of Shrewsbury. By her Cavendish had six children; an elder son who died without issue; William, who in 1618 was created earl of Devonshire; Charles, whose son William became 1st duke of Newcastle; Frances, who married Sir Henry Pierpont and was the ancestress of the dukes of Kingston; Elizabeth, who married Charles Stuart, earl of Lennox, and was the mother of Arabella Stuart; and Mary, who married Gilbert Talbot, 7th earl of Shrewsbury.

CAVETTO, in architecture, any projecting moulding (*q.v.*) with a concave profile of single curvature.

CAVIARE or CAVIAR, the roe of various species of *Acipenser* or sturgeon prepared, in several qualities, as an article of food. The word is common to most European languages and supposed to be of Turk or Tatar origin, but the Turk word *khavyah* is probably derived from the Italian *caviala;* the word does not appear in Russian.

The best caviare, which can only be made in winter and is difficult to preserve, is the loosely granulated, almost liquid kind, known in Russia as *ikra.* It is prepared by beating the ovaries and straining through a sieve to clear the eggs of the membranes, fibres and fatty matter; it is then salted with from 4% to 6% of salt. The difficulty of preparation and of transport made it a table delicacy in western Europe, where it has been known since the 16th century, as is evidenced by Hamlet's "His play . . . pleased not the million, 'twas caviare to the general."

Caviare is eaten either as an hors d'oeuvre, particularly in Russia and northern Europe, with kümmel or other liqueurs, or as a savoury, or as a flavouring to other dishes. The coarser quality, in Russia known as *pajusnaya* (from *pajus,* the adherent skin of the ovaries), is more strongly salted in brine and is pressed into a more solid form than the *ikra;* it is then packed in small barrels or hermetically sealed tins. This forms a staple article of food in eastern Europe and Russia, where the best forms of caviare are still made. The greater quantity of the coarser kinds are exported from Astrakhan, the centre of the trade. Large amounts are made each year for export in America and also in Germany, Norway and Sweden. The roe of tunny and mullet pickled in brine and vinegar, is used, under the name of "botargo," along the Mediterranean littoral and in the Levant.

CAVIGLIA, ENRICO (1862–1945), Italian soldier, was born at Finale Marina (Genoa) on May 4, 1862. After Italy's entry into World War I he was promoted to major general and commanded the Bari brigade. In June 1916 he took over the 29th division and later was promoted lieutenant general. In July 1917 he was given command of the 24th corps, which broke through the Austrian lines on the Bainsizza plateau. In June 1918 he was chosen to command the 8th army, which played an important part in the final victory of Vittorio Veneto. From January to June 1919 Caviglia was minister of war, and as such became a senator. In November of the same year he was promoted army general. In Jan. 1920 he took over the command in Venezia Giulia. His task was difficult, since the discipline of the troops had been severely shaken by the example of Gabriele d'Annunzio's Fiume raid. He restored discipline, and ultimately (Dec. 1920) did not hesitate to use force in driving D'Annunzio from Fiume. In 1926 he was made a marshal. He died March 22, 1945.

CAVITE, a municipality and capital of the province of Cavite, Luzon, Philippines, on a forked tongue of land in Manila bay, 8 mi. S. of Manila. Pop. (1948) 35,052.

A native town was already in existence there when the Spaniards arrived and took possession after their occupation of Manila. The Dutch bombarded Cavite in 1647 and it was long a revolutionary centre. In 1872 a military insurrection broke out and in 1896 there was an execution of 13 of the insurgents to whom a monument was erected by their Filipino sympathizers in 1906. The home of Emilio Aguinaldo, the insurrection leader against both Spain and the United States, was the adjoining municipality of Cavite Viejo.

On May 1, 1898, Commodore George Dewey of the United States navy commanded a naval force which overcame the Spanish fleet and captured the town. From 1898 until 1941 it was the chief naval base and coaling station of the U.S. fleet in Asiatic waters, the coaling docks being at Sangley point in the north end of the municipality. But on Dec. 7 it was attacked by Japanese forces, who held it until 1945, when the base was recaptured by the U.S. After the Philippines became independent, provisions were made to allow the U.S. to continue to hold it for certain limited activities.

The surrounding region, of volcanic origin, is fertile and produces Manila hemp, rice, sugar, copra, cacao, coffee and corn. There are convenient transportation connections with Manila. The U.S. navy established a radio station and arsenal, and remains of Spanish fortifications were still visible in modern times.

CAVOUR, CAMILLO BENSO, COUNT OF (1810–1861), Italian statesman, was born at Turin on Aug. 1, 1810. Being a younger son (his brother Gustavo was the eldest), Cavour was destined for the army, and became an engineer officer. He soon developed strongly marked Liberal tendencies and an uncompromising dislike for absolutism and clericalism, which made him a suspect in the eyes of the police and of the reactionaries. After the accession to the throne of Charles Albert, whom he always distrusted, he resigned his commission (1831). During the next few years he devoted himself to the study of political and social problems, to foreign travel and to acquiring a thorough knowledge of practical agriculture. Cavour's political ideas were greatly influenced by the July revolution of 1830 in France, which proved that a historic monarchy was not incompatible with Liberal principles, and he became more than ever convinced of the benefits of a constitutional monarchy as opposed both to despotism and to republicanism. He applied his knowledge of agriculture to the management of his father's estate at Leri, which he greatly improved, he founded the Piedmontese Agricultural society and took the lead in promoting the introduction of steam navigation, railways and factories into the country. Thus his mind gradually evolved, and he began to dream dreams of a united Italy free of

foreign influence. In 1847 the psychological moment seemed to have arrived, for the new pope, Pius IX., showed Liberal tendencies and seemed ready to lead all the forces of Italian patriotism against the Austrian domination. Cavour, although he realized that a really Liberal pope was an impossibility, saw the importance of the movement and the necessity of profiting by it. He founded a newspaper at Turin called *Il Risorgimento*, which advocated the ideas of constitutional reform. In Jan. 1848 the revolution first broke out in Sicily, and Cavour, in a speech before a delegation of journalists, declared that the king must take a decided line and grant his people a constitution. Charles Albert, after much hesitation, was induced to grant a charter of liberties (Feb. 8, 1848). Cavour continued his journalistic activity, and his articles in the *Risorgimento* came to exercise great influence both on the king and on public opinion. When the news of the revolt of the Milanese against the Austrians reached Turin on March 19, Cavour advocated war against Austria. His article in the *Risorgimento* made such an impression that it put an end to the king's vacillations, and a few days after its appearance war was declared (March 25).

During the war elections were held in Piedmont. Cavour was returned in June, and he took his seat in parliament on the right as a Conservative. He was not a good speaker, but he gradually developed a strong argumentative power, and he rose at times to the highest level of an eloquence which was never rhetorical. After the dissolution in Jan. 1849, Cavour was not re-elected. The new parliament had to discuss, in the first instance, the all-important question of whether the campaign should be continued now that the armistice was about to expire. The king decided on a last desperate throw, and recommenced hostilities. On March 23 the Piedmontese were totally defeated at Novara, a disaster which was followed immediately by the abdication of Charles Albert in favour of his son Victor Emmanuel II. The new king was obliged to conclude peace with Austria and the Italian revolution was crushed, but Cavour did not despair. There were fresh elections in July, and this time Cavour was returned. His speech on March 7, 1850, in which he said that, "Piedmont, gathering to itself all the living forces of Italy, would be soon in a position to lead our mother-country to the high destinies to which she is called," struck the first note of encouragement after the dark days of the preceding year. He supported the ministry of which Massimo d'Azeglio was president in its work of reform and restoration, and in October of the same year, on the death of Santa Rosa, he himself was appointed minister of agriculture, industry and commerce. In 1851 he also assumed the portfolio of finance, and devoted himself to the task of reorganizing the Piedmontese finances. By far the ablest man in the cabinet, he soon came to dominate it, but as a result of a quarrel with d'Azeglio he resigned; he made use of his freedom to visit England and France again, in order to sound public opinion on the Italian question. In London he found the leaders of both parties friendly. At this time Sir James Hudson was appointed British minister at Turin, where he became the intimate friend of Cavour and gave him valuable assistance. In Paris, Cavour had a long interview with Prince Louis Napoleon, then president of the republic, and also met several Italian exiles in France.

On Cavour's return he found a new cabinet crisis, and was invited to form a ministry. By Nov. 4, he was prime minister. He devoted the first years of his premiership to developing the economic resources of the country; but in preparing it for greater destinies, he had to meet the heavy expenditure by increased taxation. Cavour's first international difficulty was with Austria; after the abortive rising at Milan in Feb. 1853, the Austrian Government, in addition to other measures of repression, confiscated the estates of those Lombards who had become naturalized Piedmontese, although they had nothing to do with the outbreak. Cavour took a strong line on this question, and on Austria's refusal to withdraw the obnoxious decree, he recalled the Piedmontese minister from Vienna. Then followed the Crimean War, in which Cavour first showed his extraordinary political insight and diplomatic genius. In spite of many difficulties and opposition from both extreme Conservatives and Radicals, he negotiated Piedmontese participation in the campaign as a means of bringing the Italian question before the Great Powers. General Dabormida, the minister of foreign affairs, disapproved of this policy and resigned. The vacant portfolio was offered to d'Azeglio, who refused it; whereupon Cavour assumed it himself. On the same day (Jan. 10, 1855) the treaty with France and England was signed, and shortly afterwards 15,000 Piedmontese troops under General La Marmora were despatched to the Crimea.

Events at first seemed to justify the fears of Cavour's opponents. Cholera attacked the Piedmontese soldiers, who for a long time had no occasion to distinguish themselves in action; public opinion became despondent and began to blame Cavour, and even he himself lost heart. Then came the news of the battle of the Tchernaya, fought and won by the Italians, which turned sadness and doubt into jubilation. Joy was felt throughout Italy, especially at Milan, where the victory was the first sign of daylight amid the gloom caused by the return of the Austrians. On the summoning of the Congress of Paris at the conclusion of the war, Cavour represented Piedmont. After much discussion, and in spite of the opposition of Austria, who as mediator occupied a predominant position, Cavour obtained that Piedmont should be treated as one of the Great Powers. By his marvellous diplomatic skill, far superior to that of his colleagues, he first succeeded in isolating Austria, secondly in indirectly compromising Napoleon in the Italian question, and thirdly in getting the wretched conditions of Italy discussed by the representatives of the Great Powers. It was now manifest that the liberation of Italy was personified in him. Cavour's chief measure of internal reform during this period was a bill for suppressing all monastic orders unconnected with education, preaching or charity; this aroused strong opposition and led to the minister's resignation. But he was soon recalled, for the country could not do without him, and the bill was passed (May 29, 1855).

Cavour now saw that war with Austria was merely a question of time, and he began to establish connections with the revolutionaries of all parts of Italy. He continued to strengthen Piedmont's military resources, but he well knew that Piedmont could not defeat Austria single-handed. He would have preferred an alliance with Great Britain, who would never demand territorial compensation; but although British sympathies were with Italy, the British Government was keenly anxious to avoid war. From Napoleon more was to be hoped, for the emperor still preserved some of his revolutionary instincts, while the insecurity of his situation at home made him eager to gain popularity by winning military glory abroad; but he still hesitated, and Cavour devoted the whole of his ability to overcoming his doubts. In spite of the Orsini outrage, an "accidental" meeting between Napoleon and Cavour was arranged and took place at Plombières in July, and although no definite treaty was signed the basis of an agreement was laid, whereby France and Piedmont were to declare war against Austria with the object of expelling her from Italy, and a north Italian State was to be formed; in exchange for this help France was to receive Savoy and possibly Nice. A marriage was to be arranged between Prince Jerome Bonaparte and Princess Clothilde, Victor Emmanuel's daughter. But the emperor still hesitated, and Cavour saw that the only way to overcome the many obstacles in his path was to force Austria's hand. Then there was the danger lest an Italy freed by French arms should be overwhelmed under French predominance; for this reason Cavour was determined to secure the co-operation of volunteers from other parts of Italy, and that the war should be accompanied by a series of risings against Austria and the local despots.

The moment war was seen to be imminent, parties of Italians of all classes, especially Lombards, poured into Piedmont to enlist in the army. Cavour also had a secret interview with Garibaldi, with whom he arranged to organize volunteer corps so that the army should be not merely that of Piedmont, but of all Italy. Every day the situation grew more critical, and on Jan. 10, 1859 the king in his speech from the throne pronounced the memorable words "that he could not remain deaf to the cry of pain (*il grido di dolore*) that reached him from all parts of Italy" —words which, although actually suggested by Napoleon, rang

like a trumpet-call throughout the land. In the meanwhile the marriage negotiations were concluded, and during the emperor's visit to Turin a military convention was signed between the two States, and Savoy and Nice were promised to France as a reward for the expulsion of the Austrians from Italy. But Napoleon, ever hesitating, jumped at the Russian proposal to settle the Italian question by means of his own favourite expedient, a congress. To this Austria agreed on condition that Piedmont should disarm and should be excluded from the congress; England supported the scheme, but desired that all the Italian States should be represented. Cavour was in despair at the turn events were taking but decided at last reluctantly to accept the proposal, lest Piedmont should be abandoned by all, while he clung to the hope that Austria would reject it. On April 19, the Austrian emperor, on the advice of the military party, did reject it; and on the 23rd, to Cavour's inexpressible joy, Austria sent an ultimatum demanding the disarmament of Piedmont. Cavour replied that his Government had agreed to the congress proposed by the Powers and that it had nothing more to say. On quitting the chamber that day he said to a friend: "I am leaving the last sitting of the last Piedmontese parliament"—the next would represent united Italy. France now allied herself definitely with Piedmont, and England, delighted at Cavour's acquiescence became wholly friendly to the Italian cause. A few days later Austria declared war.

As La Marmora now took the chief command of the army Cavour added the ministry of war to the others he already held. His activity at this time was astounding, for he was virtually dictator and controlled single-handed nearly all the chief offices of the State. The French and Piedmontese forces defeated the Austrians in several battles, and the people rose in arms at Parma, Modena, Florence and Bologna; the local princes were expelled and provisional governments set up. Cavour sent special commissioners to take charge of the various provinces in Victor Emmanuel's name. But these events, together with Prussia's menacing attitude, began to alarm Napoleon, who, after Solferino, concluded an armistice with Austria at Villafranca on July 8, without previously informing Cavour. When Cavour heard of it he was thunderstruck; he immediately interviewed the king at Monzambano, and in violent, almost disrespectful language implored him not to make peace until Venice was free. But Victor Emmanuel saw that nothing was to be gained by a refusal, and much against his own inclination, signed the peace preliminaries at Villafranca, adding the phrase, "pour ce qui me concerne," which meant that he was not responsible for what the people of other parts of Italy might do (July 12). Lombardy was to be ceded to Piedmont, Venetia to remain Austrian, the deposed princes to be reinstated, and the pope made president of an Italian confederation.

The cabinet resigned the next day, and Cavour privately advised the revolutionists of central Italy to resist the return of the princes, by force if necessary. Palmerston, who had meanwhile succeeded Malmesbury as foreign minister, informed France and Austria that Great Britain would never tolerate their armed intervention in favour of the central Italian despots. On Nov. 10, peace was signed at Zürich, and on the fall of the Rattazzi-La Marmora cabinet the king, in spite of the quarrel at Monzambano, asked Cavour to take office again. Napoleon still refused to consent to the union of Tuscany with Piedmont, but Cavour saw that Napoleon might be ready to deal; although the bargain of the preceding year had not been exactly fulfilled, as the Austrians were still in Venice, he again brought forward the question of Nice and Savoy. On March 24, the treaty was signed, and the emperor's opposition to the annexation of central Italy withdrawn. On April 2, the parliament representing Piedmont, the duchies of Parma and Modena, Tuscany and Romagna, met, and Cavour had the difficult and ungrateful task of explaining the cession of Nice and Savoy. In spite of some opposition, the agreement was ratified by a large majority.

The situation in the kingdom of Naples was now becoming critical, and Cavour had to follow a somewhat double-faced policy, on the one hand negotiating with the Bourbon king (Francis II.), suggesting a division of Italy between him and Victor Emmanuel, and on the other secretly backing up the revolutionary agitation. Having now learnt that Garibaldi was planning an expedition to Sicily with his volunteers, he decided not to oppose its departure; on May 5, it sailed from Quarto near Genoa. Garibaldi with his immortal Thousand landed at Marsala, and the whole rotten fabric of the Bourbon Government collapsed. He crossed over to the mainland, and entered Naples in triumph. But Cavour feared, that, although Garibaldi himself had always loyally acted in the king of Italy's name, the republicans around him might lead him to commit some imprudence and plunge the country into anarchy, and that Garibaldi might invade the papal States, which would have led to further international complications. But the pope had made considerable armaments; his forces, consisting largely of brigands and foreigners under the French general Lamoricière, maintained a menacing attitude on the frontier; Cavour decided on the momentous step of annexing the papal States with the exception of the Roman province. The Italian forces crossed the frontier from Romagna on Sept. 11, and were everywhere received with open arms by the people; Ancona was taken, Lamoricière was defeated and captured at the battle of Castelfidardo, and on the 20th King Victor marched into the Neapolitan kingdom. On Oct. 1, Garibaldi defeated the Neapolitan troops on the Volturno, and Gaeta alone, where King Francis of Naples had retired, still held out.

Cavour had to use all his tact to restrain Garibaldi from marching on Rome and at the same time not to appear ungrateful. He refused to act despotically, and summoned parliament to vote on the annexation, which it did on the 11th. Two days later Garibaldi magnanimously gave in to the nation's will and handed his conquests over to King Victor as a free gift. Gaeta surrendered on Feb. 13, and King Francis retired to Rome. Parliament was dissolved once more; the new chamber showed an overwhelming majority in favour of Cavour, and Victor Emmanuel was proclaimed king of Italy.

The last question with which Cavour had to deal was that of Rome. In October he declared in parliament that Rome must be the capital of Italy, for no other city was recognized as such by the whole country, and in Jan. 1861 a resolution to that effect was passed. But owing to Napoleon's attitude he had to proceed warily, and made no attempt for the present to carry out the nation's wishes. At the same time he was anxious that the Church should preserve the fullest liberty, and he believed in the principle of "a free Church in a free State." The long strain of these last years had been almost unbearable, and at last began to tell; the negotiations with Garibaldi were particularly trying, for while the great statesman wished to treat the hero and his volunteers generously, he could not permit all the Garibaldian officers to be received into the regular army with the same ranks they held in the volunteer forces. This question, together with that of Nice, led to a painful scene in the chamber between the two men, although they were formally reconciled a few days later. For some time past Cavour had been unwell and irritable, and the scene with Garibaldi undoubtedly hastened his end. A fever set in, and after a short illness he passed away on June 6, 1861. He was buried on his ancestral estate of Santena.

The death of Cavour was a terrible loss to Italy; there remained many problems to be solved in which his genius and personality were urgently needed. But the great work had been carried to such a point that lesser men might now complete the structure. He is undoubtedly the greatest figure of the *Risorgimento*, and although other men and other forces co-operated in the movement, it was Cavour who organized it and skilfully conducted the negotiations necessary to overcome all, apparently insuperable, obstacles. (L. V.)

CAVOUR (anc. *Caburrum* or *Forum Vibii*), a village of Piedmont, Italy, in the province of Turin, 32 mi. S.W. by rail and steam tram (via Pinerolo) from the town of Turin. Pop. 1,547 (town); 6,244 (commune). It lies on the north side of a huge isolated mass of granite (the Rocca di Cavour) which rises from the plain. On the summit was the Roman village. The town gave its name to the Benso family of Chieri, who were raised to the marquisate in 1771, and of which the statesman Cavour was a member.

CAVY, the name of several South American rodents of the family Caviidae (*see* RODENTIA); originally it was confined to the domesticated guinea pig and its allies of the genus *Cavia*. (The word "guinea" here may be a corruption of "Guiana" but more probably it means "foreign.") The true cavies are small, self-coloured animals, with short, rounded ears and no tail. They are partly diurnal and live in burrows. The diet is vegetarian and their cries are faint squeaks and grunts. Unlike the prolific guinea pig, which begins to breed at two months old and may be the parent of several hundred individuals in a year, the wild cavies breed only once a year, producing one or two young at a time. These are born in a very advanced stage of development and begin to feed themselves the following day.

Cavies are widely distributed in South America. The original of the domestic race is *C. cutleri* of Peru. *C. niata* is found at great elevations in the Andes. The restless cavy of Brazil is *C. pamparum*. The Patagonian cavy or mara (*Dolichotis australis*) resembles a hare in shape and habits, but lives in a burrow. Fossil species of this genus, of which there is a second smaller type in Argentina, have been found in Brazil and the Argentine.

CAWDOR, village and civil parish, Nairnshire, Scotland. Pop. (1931) 767. The village is situated 5 mi. S.S.W. of Nairn and 3 mi. from Gollanfield Junction on the L.M.S.R. In the vicinity is a large distillery. The castle was the scene, according to the tradition which Shakespeare has perpetuated, of the murder of King Duncan by Macbeth, thane of Cawdor (or Calder), in 1040. Since the oldest part of the structure dates from 1454, however, and seemingly had no predecessor, the tradition has no foundation in fact. The building stands on the rocky bank of Cawdor burn, a right-bank tributary of the Nairn. The massive keep with small turrets is the original portion of the castle, and to it were added, in the 17th century, the modern buildings forming two sides of a square. It is the seat of Earl Cawdor. Kilravock (pronounced *Kilrawk*) castle, 1½ mi. W. of Cawdor, commands the left bank of the Nairn. Its keep dates from 1460, and the later buildings belong to the 17th century. It has been continuously tenanted by the Roses, who settled at Kilravock in 1293, after which date son succeeded father in direct descent. Queen Mary was received at the castle in 1562, and Prince Charles Edward was entertained four days before the battle of Culloden. The gardens are beautiful.

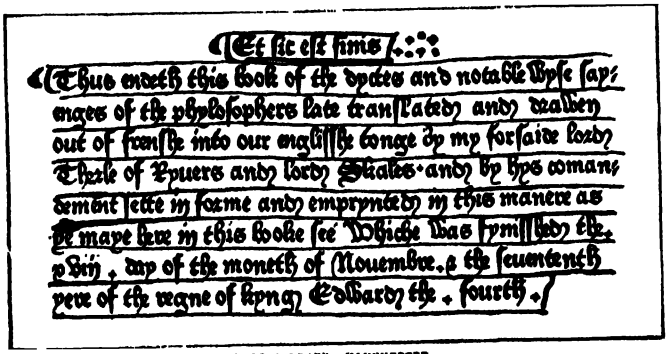
CAWNPORE, a city and district of British India in the Allahabad division of the United Provinces. The city is situated on the south bank of the Ganges, 40 m. south-west of Lucknow, and formed from early times a frontier outpost of the people of Oudh and Bengal against their northern neighbours. Clive selected it, on account of its commanding position, as the cantonment for the brigade of troops lent him by the nawab of Oudh. In 1801, when the Ceded Provinces were acquired by the East India Company, it became the chief British frontier station, but by the time of the Mutiny the frontier had left it behind, and it was denuded of troops. It is now again a military station of some importance, and a very large railway centre. But its industrial development has been unique in northern India. Starting with a government harness factory, the manufacture of leather goods in every form has attained the position of a first-class industry. There are also large cotton-mills, a woollen manufactory with a world-wide reputation and a number of engineering and other minor industries. Extensive city improvements have been launched in order to keep pace with the sanitary requirements of the growing labour force. On the outskirts of the city is a fine agricultural college and demonstration farm. The population of the city and cantonment in 1941 was 487,324.

The name of Cawnpore is indelibly connected with the blackest episode in the history of the Indian Mutiny—the massacre here in July 1857 of hundreds of women and children by the Nana Sahib. The entrenchment, where General Sir H. M. Wheeler with his small band of soldiers and the European and Eurasian residents were exposed for 21 days to the fire of the mutineers, is merely a bare field. About three-quarters of a mile away, on the banks of the river Ganges, is the Massacre Ghat. A grassy road between banks 10 to 12 ft. high leads down to the river, and it was among the trees on these banks that the murderers concealed themselves and shot down the little garrison as soon as they were embarked in the boats which were to take them to safety. On the Ghat itself, or temple steps down to the water, some 600 helpless people were slain, in spite of a promise of safe conduct from the Nana. The remaining 200 victims, who had escaped the bullets of the siege and survived the butchery of the river bank, were massacred afterwards and cast down the famous well of Cawnpore, which is now marked by a memorial and surrounded by gardens. The memorial is crowned by the figure of an angel in white marble, and on the wall of the well itself is the following inscription:

Sacred to the perpetual Memory of a great company of Christian people, chiefly Women and Children, who near this spot were cruelly murdered by the followers of the rebel Nana Dhundu Pant, of Bithur, and cast, the dying with the dead, into the well below, on the xvth day of July, MDCCCLVII.

The DISTRICT OF CAWNPORE is situated between the Ganges and Jumna rivers, and is a portion of the well-watered and fertile tract known as the Doab, the total area being 2,372 sq.mi. The general inclination of the country is from north to south. Besides the two great rivers, the principal streams are the Arand or Rhind, the Kavan or Singar, the Isan and the Pandu. The district is watered by four branches of the Ganges canal. The population in 1941 was 1,556,247.

CAXTON, WILLIAM (*c.* 1422–1491), the first English printer, was born somewhere in the Weald of Kent. The name, which was apparently pronounced Cauxton, is identical with Causton, the name of a manor in the parish of Hadlow. The date of Caxton's birth was arbitrarily fixed in 1748 by Oldys as 1412. Blades, however, inferred that in 1438, when he was apprenticed to Robert Large, he would not have been more than 16 years of age. Robert Large was a rich silk mercer who became lord mayor of London in 1439, and the fact of Caxton's apprenticeship to him argues that Caxton's own parents were in a good position. When Large died in 1441, Caxton was probably sent direct to Bruges, then the central foreign market of the Anglo-Flemish trade, for he presently entered business there on his own account. In 1450 his name appears in the Bruges records as standing joint surety for the sum of £100; and in 1463 he was acting governor of the company of Merchant Adventurers in the Low Countries. This association, sometimes known as the "English Nation," was dominated by the Mercers' Company, to the livery of which Caxton had been formally admitted in London in 1453. In 1464 he was appointed to negotiate with Philip, duke of Burgundy, the renewal of a treaty concerning the wool trade, which was about to expire. These attempts failed, but he was again employed in a similar but successful mission in Oct. 1468 to the new duke, Charles the Bold, who had just married Princess Margaret of York, sister of Edward IV. The last mention of Caxton in the capacity of governor of the "English Nation" is on Aug. 13, 1469, and it was probably about that time that he entered the household of the duchess Margaret, possibly in the position of commercial adviser.



He had already begun his translation of the popular mediaeval romance of Troy, *The Recuyell of the Historyes of Troye*, from the French of Raoul le Fèvre; and, after laying it aside for some time, he resumed it at the wish of the duchess Margaret, to whom the ms. was presented. From July 1471 until after Midsummer 1472 Caxton was in Cologne, and it was there, as his disciple

Wynkyn de Worde tells us, that he learned the art of printing. On his return to Bruges, he set up a press, in partnership with Colard Mansion, and there his *Recuyell* was printed in 1474 or 1475. His second book, *The Game and Playe of Chesse,* from the *Liber de ludo scacchorum* of Jacobus de Cessolis through the French of Jehan de Vignay, was finished in 1474, and printed in 1476; the last book printed by Mansion and Caxton at Bruges was the *Quatre derrenieres choses,* an anonymous treatise usually known as *De quattuor novissimis.*

CAXTON'S DEVICE, CONSISTING OF HIS INITIALS AND TRADE MARK, FOUND IN 11 OF HIS 102 BOOKS AND BROADSIDES. IT IS 5½"X4½"

Then Caxton returned to England and established himself, at Michaelmas, 1476, in the almonry at Westminster at the sign of the Red Pale. The first known piece of printing issued from the Caxton press in England is an *Indulgence* printed by Caxton and issued by Abbot Sant on Dec. 13, 1476, which was discovered in the Record Office in 1928 by Mr. S. C. Ratcliffe. The first dated book printed in England was Lord Rivers' translation (revised by Caxton) of *The Dictes and sayenges of the phylosophers* (1477) (*see* BLACK LETTER). The date, Nov. 18, 1477, is given in the colophon to the copy in the John Rylands Library, Manchester, the only one which possesses the colophon. From this time until his death Caxton was busy writing and printing. His services to English literature, apart from his work as a printer (*see* TYPOGRAPHY), are very considerable. His most important original work is an eighth book added to the *Polychronicon* (vol. viii. in the Rolls Series edition) of Ralph Higden. Caxton revised and printed John of Trevisa's work, and brought down the narrative himself from 1358 to 1460, using as his authorities *Fasciculus temporum,* a popular work in the 15th century, and an unknown *Aurcus de universo.* He printed Chaucer's *Canterbury Tales* (1478? and 1483), *Troilus and Creseide* (1483?), the *House of Fame* (1483?), and the translation of Boethius (1478?); Gower's *Confessio Amantis* (1483), and many poems of Lydgate. His press

BY COURTESY OF THE JOHN RYLANDS LIBRARY, MANCHESTER

COLOPHON TO CAXTON'S "DICTES AND SAYENGES OF THE PHYLOSOPHERS" (1477), THE FIRST BOOK PRINTED IN ENGLAND TO BEAR A DATE

The colophon, an inscription placed at the end of a book in early times, contained information now usually found on the title page

was, however, not worked for purely literary ends, but was a commercial speculation. For the many service-books which he printed there was no doubt a sure sale, and he met the taste of the upper classes by the tales of chivalry which issued regularly from his press. He printed Malory's *Morte d'Arthur,* and himself translated from the French the *Boke of Histories of Jason* (1477?), *The Historye of Reynart the Foxe* (from the Dutch, 1481 and 1489?), *Godfrey of Boloyne* or *The Siege and Conqueste of Jherusalem* (1481), *The Lyf of Charles the Grete* (1485), *The Knyght Parys and the Fayr Vyenne* (1485), *Blanchardyn and Eglantine* (1489?), *The Foure Sonnes of Aymon* (1489?); also the *Morale Proverbs* (1478), and the *Fayttes of Armes and of Chyualrye* (1489) of Christine de Pisan. The most ambitious production of his press was perhaps his version of the *Golden Legend,* the translation of which he finished in Nov. 1483. It is based on the lives of the saints as given in the 13th century *Legenda aurea* of Jacobus de Voragine, but Caxton chiefly used existing French and English versions for his compilation. The book is illustrated by 70 woodcuts, and Caxton says he was only encouraged to persevere in his laborious and expensive task by the liberality of William, earl of Arundel. The idleness which he so often deprecates in his prefaces was no vice of his, for in addition to his voluminous translations his output as a printer was over 18,000 pages, and he published 96 separate works or editions of works, with apparently little skilled assistance.

The different founts of type used by Caxton are illustrated by Blades and Duff, and there is an excellent selection of Caxtons in the British Museum and in the University library at Cambridge. His books have no title-pages, and from 1487 onwards are usually adorned with a curious device, consisting of the letters W.C. separated by a trade mark, with an elaborate border above and below. The flourishes on the trade mark have been fancifully interpreted as S.C. for Sancta Colonia, implying that Caxton learnt his art at Cologne, and the whole mark has been read as 74, for 1474, the date of his first printed book. This device was subsequently adopted with small alterations by his successor at the Westminster press, Wynkyn de Worde. The first of his books containing woodcut illustrations was his *Myrrour of the World* (1481), translated from Vincent de Beauvais, but he had used a woodcut initial letter in his broadside *Indulgence* printed in 1476.

No record of Caxton's marriage or of the birth of his children has been found, but Gerard Croppe was separated from his wife Elizabeth, daughter of William Caxton, before 1496, when Croppe made certain claims in connection with his father-in-law's will.

BIBLIOGRAPHY.—Earlier biographies of Caxton were superseded by the work of William Blades, whose *Life and Typography of William Caxton* (1861–63) remains the standard authority. It contains a bibliography of each of the works issued from Caxton's press. For later discoveries *see* E. Gordon Duff, *William Caxton* (1905) and H. R. Plomer, *William Caxton* (1925). Many of Caxton's translations are available in modern reprints.

CAYAPAS, a tribe of South American Indians, belonging to the Barbacoan (*q.v.*) linguistic stock or sub-stock. Their habitat is the lower Cayapas river and adjacent coasts in northern Ecuador. Traditionally they formerly lived in the upland region about Quito, moving to the coast a short time before the first appearance of Europeans.

They became much mixed with Negroes, and relatively little of their original culture survives.

See S. A. Barrett, "The Cayapa Indians of Ecuador" (Museum of the American Indian, *Indian Notes and Monographs,* no. 40. New York, 1925).

CAYENNE, capital of French Guiana, is a port standing at the northwestern end of the "isle of Cayenne" formed by the estuaries of the Cayenne and the Mahoury rivers. Its plan is that of a rectangle lying along the sea-front. Its streets, built on a rectangular pattern, are lined by brick or wooden houses of one or two stories. The church of the Holy Saviour and the Jesuits' house are of some antiquity; and there are other interesting buildings, including the Préfecture, around the Place d'Armes. To the west, Mont Cépérou and the Fort Saint-Michel dominate the harbour.

Suitably purified water is available at the rate of 5,000 cu.m. per day. Fever is kept down by draining the marshes and by spraying DDT.

The sea wind mitigates the heat, and the climate, though humid, is healthful. Population (1946) 10,961.

The harbour is liable to be silted up, and there is a bar at the entrance, allowing only 3.80 m. of draught at high tide. There is a metal wharf, but big ships unload at Larivot (a few kilometres distant) or at the Iles du Salut. Once a month a ship goes between Cayenne and Fort de France (Martinique), and aircraft of the New York-Buenos Aires line land four times a week at the aerodrome.

An avenue running along the sea-front joins Cayenne to the suburbs of Chaton and Montabo, where are the buildings of the Institut Français d'Amérique Tropicale and the Institut Pasteur. (For history, *see* GUIANA.) (HU. DE.)

CAYENNE PEPPER (*Guinea Pepper, Spanish Pepper, Chilly*), a preparation from the dried fruit of various species of *Capsicum*, a genus of the family Solanaceae. The true peppers are members of a totally distinct family, Piperaceae. The fruits of *Capsicum* have a strong, pungent flavour. The capsicums bear a greenish-white flower, with a star-shaped corolla and five anthers standing up in the centre of the flower like a tube, through which projects the slender style. The podlike fruit consists of an envelope at first fleshy and afterwards leathery, within which are the spongy pulp and several seeds. The plants are herbaceous or shrubby; the leaves are entire, and alternate, or in pairs near one another; the flowers are solitary and do not arise in the leaf-axils. There are about 30 species, natives of Central and South America. In the United States chief production is in Louisiana and South Carolina. The output is about 1,000,000 lb. dried. The principal source of cayenne pepper is *C. annuum*, the spur or goat pepper, a dwarf shrub, a native of South America, but commonly cultivated in the East Indies. It produces a small, narrow, bright red pod, having very pungent properties.

Chillies, the dried fruit of capsicums, are used to make chilly-vinegar, as well as for pickles. Cayenne pepper is manufactured from the ripe fruits, which are dried, ground, mixed with wheat flour and made into cakes with yeast; the cakes are baked till hard, like biscuit, and then ground and sifted.

Chillies have been in use from time immemorial; they are eaten in great quantity by the people of Guiana and other warm countries and in Europe are consumed both as a spice and as medicine.

CAYEY, an interior town of Puerto Rico. Pop. (1950) 18,402, an increase of 227% over 1940. The population of the municipal district in 1950 was 36,634.

The altitude is 1,400 ft.; average temperature about 71° F. Cayey, one of the most healthful towns of the island, is on the military highway built by Spain diagonally across the island from San Juan on the Atlantic ocean to Ponce on the Caribbean sea. One of the branches of this highway extends to Guayama and another to Salinas, both on the Caribbean.

Because of its healthful climate the Spanish rulers established a military post there; the Americans succeeding them used it as a U.S. army post.

The town is the centre of a region where tobacco and coffee of superior quality are produced, and has many warehouses and factories.

CAYLEY, ARTHUR (1821–1895), English mathematician, was born at Richmond, Surrey, on Aug. 16, 1821. He entered Trinity college, Cambridge, as a pensioner, became a scholar in May 1840, senior wrangler, first Smith's prizeman and fellow of Trinity in 1842 and a major fellow in 1845. In 1846, he entered at Lincoln's Inn, and became a pupil of the conveyancer Mr. Christie. While practising law he met J. J. Sylvester, and the two spent much time profitably discussing mathematics. He was called to the bar in 1849, and remained at the bar till he was elected to the new Sadlerian chair of pure mathematics at Cambridge in 1863, when he married Susan, daughter of Robert Moline of Greenwich. He held this chair till his death, on Jan. 26, 1895. His 800 mathematical papers, published in 13 large quarto volumes by the Cambridge University press, treat of nearly every subject of pure mathematics, and of theoretical dynamics and spherical and physical astronomy. He was as much a geometrician as an analyst. Of special mention are his ten memoirs on quantics in which he developed the theory of algebraic invariants (1854–78), his creation of the theory of matrices, his researches on the theory of groups, his memoir on abstract geometry, the geometry of *n*-dimensional space, a subject which he created, his introduction to geometry of the "absolute," his researches on the higher singularities of curves and surfaces, the classification of cubic curves, additions to the theories of rational transformation and correspondence, the theory of the twenty-seven lines that lie on a cubic surface, the theory of elliptic functions, the attraction of ellipsoids, and the British association reports, 1857 and 1862, on recent progress in general and special theoretical dynamics, and on the secular acceleration of the moon's mean motion. Competent judges have compared him with Leonhard Euler for his range, analytical power and introduction of new and fertile theories. He received nearly every academic distinction that can be conferred upon a man of science. His nature was noble and generous, and the universal appreciation of this fact gave him great influence in his university. His recreations were the Victorian classics, water-colour sketching and architecture. His portrait, by Lowes Dickinson, was placed in the hall of Trinity college in 1874, and his bust, by Henry Wiles, in the library of the same college in 1888.

CAYLUS, ANNE CLAUDE, COMTE DE, Marquis d'Esternay, baron de Bransac (1692–1765), French archaeologist and man of letters, was born in Paris. His mother, the comtesse de Caylus (1673–1729), was a cousin of Mme. de Maintenon, who brought her up like her own daughter. She wrote valuable memoirs of the court of Louis XIV entitled *Souvenirs;* these were edited by Voltaire (1770) and by many later editors, notably by Ch. Asselineau (1860). Caylus was on active service with the French army from 1709–14. After the Peace of Rastadt he travelled in Italy, Greece, the East, England and Germany. He became an active member of the Academy of Painting and Sculpture and of the Academy of Inscriptions. Among his works are *Recueil d'antiquités égyptiennes, étrusques, grecques, romaines et gauloises* (7 vol. 1752–67), *Numismata Aurea Imperatorum Romanorum*, and a *Mémoire* (1755) on the method of encaustic painting with wax mentioned by Pliny, which he claimed to have rediscovered. Caylus was himself an admirable engraver; he also caused engravings to be made of Bartoli's copies from ancient pictures. He encouraged young artists, but his patronage was somewhat capricious. Diderot expressed this fact in an epigram in his *Salon* of 1765: "La mort nous a délivrés du plus cruel des amateurs." The Comte de Caylus had quite another side to his character.

He had a thorough acquaintance with the gayest and most disreputable sides of Parisian life, and left a number of more or less witty stories dealing with it. These were collected (Amsterdam, 1787) as his *Oeuvres badines complètes.* The best of them is the *Histoire de M. Guillaume, cocher* (*c.* 1730).

CAYMAN (or CAIMAN), the name applied to the broad-snouted crocodilians of South America. The black cayman (*Melanosuchus niger*) of the Amazon is a large species, reaching 16 ft. in length. Other smaller species (*Caiman* spp.) are extremely abundant in tropical America. (*See* CROCODILIAN.) (K. P. S.)

CAYMAN ISLANDS, three low-lying islands in the West Indies, Grand Cayman, Little Cayman and Cayman Brac, are between 79° 44′ and 81° 27′ W. and 19° 15′ and 19° 45′ N., a dependency of Jamaica, which lies 110–156 mi. E.S.E. Grand Cayman, a flat rock-bound island protected by coral reefs, is approximately 20 mi. long and 8 mi. broad at a maximum. It has two towns, Georgetown and Boddentown. Little Cayman and Cayman Brac are both about 60 mi. N.E. of Grand Cayman. While the soil is shallow and not infertile, commerce is dependent almost exclusively on the various marine industries. The thatch palm *Thrinax argentea* is used for the manufacture of thatch rope for export to Jamaica, but the main industry is the catching of turtles, sharks and sponges. The export of phosphate, coconuts and sisal has ceased. Local mahogany is used to build yachts and schooners.

The government is administered by a commissioner, and the laws passed by the local legislature are subject to the assent of the governor of Jamaica. Pop. (census 1943) 6,670. Land area 93 sq.mi.

The islands were discovered by Columbus, who named them Tortugas, from the turtles with which the surrounding seas abound. They were never occupied by the Spaniards and were colonized from Jamaica by the British.

CAYUGA AND SENECA CANAL: *see* NEW YORK STATE BARGE CANAL SYSTEM.

CAYUSE, an Indian tribe (of the Waiilatpuan linguistic family), that formerly inhabited northeastern Oregon and part of Washington and was noted for its horses and warlike character.

They were closely allied with the Wallawalla and Nez Percés tribes, and there was a great deal of intermarriage, particularly with the latter tribe. The Cayuse signed the treaty of 1855 establishing the Umatilla reservation, where they then lived. The tribe's population was officially given as 404 in 1904, but no Cayuse of pure blood was found on the reservation at the beginning of the 20th century.

Marcus Whitman, who had established a mission near the present city of Walla Walla, Wash., in 1838, his wife and 12 others were massacred in an attack by the Cayuse in 1847. The Indians blamed Whitman, who was a doctor, for the large number of deaths caused by disease. Volunteer troops carried on a prolonged, indecisive campaign against the tribe until five Indians, who confessed to the murders, were voluntarily surrendered in 1850.

In the western states of the United States the term cayuse refers to an Indian pony. In *Three Thousand Miles Through the Rocky Mountains* (1869), A. K. McClure used the word in this sense in his remark that "Twice our kiyuse broke nearly out of the harnass. . . . The kiyuse is never perfectly tamed."

CAYUVAVAN, a linguistic stock of South American Indians comprising but a single tribe. The validity of this stock is doubtful. The Cayuvavas formerly lived in northern Bolivia on and west of the Mamore river for some 69 mi. above its confluence with the Guaporé. The surviving remnants are now mainly settled at the mission of Exaltacion de Santa Cruz. The Indians of this group were sedentary agriculturists, and known as the best canoemen of the region. They appear to have retained little of their old culture and, like many of the tribes of this area, are very little known.

See A. D'Orbigny, *L'Homme Americain* (Paris, 1839).

CAZALÈS, JACQUES ANTOINE MARIE DE (1758–1805), French orator and politician, was born at Grenade in Languedoc, of a family of the lower nobility. Before 1789 he was a cavalry officer, but in that year was returned as deputy to the states general. In the Constituent Assembly he belonged to the section of moderate royalists who sought to set up a constitution on the English model, and his speeches in favour of retaining the right of war and peace in the king's hands and on the organization of the judiciary gained the applause even of his opponents. After the insurrection of Aug. 10, 1792, which led to the downfall of royalty, Cazalès emigrated. He fought in the army of the *émigrés* against revolutionary France, lived in Switzerland and in England, and did not return to France until 1803. He died on Nov. 24, 1805. His son, Edmond de Cazalès, wrote philosophical and religious studies.

See *Discours de Cazalès,* ed. by Chare (1821), with an introduction; F. A. Aulard, *Les Orateurs de la Constituante* (2nd ed., 1905).

CAZALIS, HENRI (1840–1909), French poet and man of letters, was born at Cormeilles-en-Parisis (Seine-et-Oise). He wrote under the pseudonyms of Jean Caselli and Jean Lahor. His oriental habits of thought earned for him the title of the "Hindou du Parnasse contemporain."

His works include: *Chants populaires de l'Italie* (1865); *Vita tristis, Réveries fantastiques, Romances sans musique* (1865); *Le Livre du néant* (1872); *Henry Regnault, sa vie et son oeuvre* (1872); *L'Illusion* (1875–93); *Melancholia* (1878); *Cantique des cantiques* (1885); *Les Quatrains d'Al-Gazali* (1896); *William Morris* (1897). *See* P. Bourget in *Anthologie des poètes fr. du XIX.e siècle* (1887–88); J. Lemaître, *Les Contemporains* (1889); E. Faguet in *Revue bleue* (Oct. 1893).

CAZEMBE, the name of an African kingdom which was situated south of Lake Mweru and north of Lake Bangweulu, between 9° and 11° S. In 1894 it was divided between Northern Rhodesia and Belgian Congo. The Cazembe kingdom was named after Muata Cazembe, the hereditary name of its ruler. It was founded by the Baluba, who formed a powerful state in the Kasai region. Muata Yamvo, the Baluba ruler, desiring to control the salt deposits of the Bangweulu, conquered the area early in the 17th century. Baluba formed the aristocracy of the conquered country, and a Baluba was appointed ruler with the title Muata Cazembe. Although autonomous in its political affairs, Cazembe remained nominally dependent on the Baluba state until 1875. Economically, the country was well developed on account of its ivory trade monopoly with Arabs and Portuguese on the east coast. Also, the copper mines of Katanga were an important source of wealth. (Under European control the Katanga copper mines developed into large industries which in 1953 supplied about one-sixth of the world's production.) About 1875 the Baluba dynasty was overthrown by Msiri, an east African adventurer of the Nyamwezi tribe, who conquered Cazembe and the adjacent areas. After Msiri's death the kingdom disintegrated rapidly. Cazembe was first visited in 1796 by Manoel Caetano Pereira, a Portuguese merchant; F. J. M. de Lacerda visited Cazembe in 1798 and David Livingstone in 1868. The Cazembe dynasty still survives in the paramount chieftaincy of the Balunda tribe in the Kawambwa district of Northern Rhodesia, where the present Cazembe is a descendant of the ancient kings.

See Brohez, "Ethnographie katangaise," *Bulletin, Société Belge de Geographie* (Brussels, 1909); R. F. Burton (ed.), *The Lands of the Cazembe* (London, 1873). (H. A. Wr.; X.)

CAZIN, JEAN CHARLES (1841–1901), French painter, was born at Samer, Pas-de-Calais, May 25, 1841, and died at Le Lavandou, Var, March 27, 1901. He studied in Paris and at Tours and in 1871 was persuaded by Alphonse Legros (*q.v.*) to go to England. There he made designs for the Fulham pottery and, more important, came under the sway of the Pre-Raphaelites, whose influence shows in his earlier religious pictures, such as "Hagar and Ishmael" (1880, Luxembourg).

Later he turned to idealistic landscape with subordinate figures, in the general tradition of J. F. Millet and of J. B. C. Corot (*e.g.*, "Souvenir de fête" [1881, Petit Palais, Paris] and "Journée faite" [1888, Lyons]).

See L. Bénédite, *J.-C. Cazin* (Paris, 1901).

CAZOTTE, JACQUES (1719–1792), French author, was born at Dijon. He was educated by the Jesuits, and at 27 obtained a public office at Martinique, returning to Paris in 1760 with the rank of commissioner-general. The most famous of his works is the *Diable amoureux* (1772), a tale with a Spanish setting in which the hero raises the devil. About 1775 Cazotte embraced the views of the Illuminati, declaring himself possessed of the power of prophecy. It was upon this fact that La Harpe based his famous *jeu d'esprit,* in which he represents Cazotte as prophesying the most minute events of the Revolution. On the discovery of some fantastic letters in Aug. 1792, Cazotte was arrested; and though he escaped for a time through the heroism of his daughter he was executed on Sept. 25.

Other works by Cazotte are *Les Mille et une fadaises* (1742; Eng. trans. 1927); and a prose epic *Ollivier* (1762). The only complete edition is the *Oeuvres badines et morales, historiques et philosophiques de Jacques Cazotte* (1816–17), though more than one collection appeared during his lifetime. An edition de luxe of the *Diable amoureux* was edited (1878) by A. J. Pons, and a selection of Cazotte's *Contes,* edited (1880) by Octave Uzanne, is included in the series of *Petits Conteurs du XVIIIe siècle.* The best notice of Cazotte is in the *Illuminés* (1852) of Gérard de Nerval.

CAZUNGO: *see* ANGOLA.

"C" BATTERY is an electric battery, used in radio circuits. It is connected between the cathode or negative electrode and the grid of a vacuum tube and supplies a direct voltage to the grid.

CEANOTHUS, a showy genus of North American shrubs and woody vines of the buckthorn family (Rhamnaceae), comprising more than 50 species found chiefly in the Pacific coast region, 30 of which are native to California. The small white or blue flowers are borne in handsome dense panicles or umbels. Several are grown as garden plants. Only two species occur east of the Rocky mountains—the New Jersey tea (*C. americanus*), so called because its leaves were used as tea during the American Revolution, and *C. ovatus.* The genus attains its maximum development in the foothills and mountains of California, often constituting a considerable part of the chaparral. Noteworthy representatives are the California lilac and the Oregon tea-tree (*qq.v.*).

See M. Van Rensselaer and H. E. McMinn, *Ceanothus,* xii, 1–308, illus. (1942).

CEARÁ, a northern maritime State of Brazil, bounded north by the Atlantic, east by the Atlantic and the States of Rio Grande

do Norte and Paraíba, south by Pernambuco, and west by Piauí, and having an area of 57,371 sq. miles. It lies partly upon the northeast slope of the great Brazilian plateau, and partly upon the sandy coastal plain. Its surface is a succession of great terraces, facing north and northeast, formed by the denudation of the ancient sandstone plateau which once covered this part of the continent; the terraces are seamed by watercourses, and their valleys broken by hills and ranges of highlands, usually described as mountain ranges, but in fact only the remains of the ancient plateau, capped with horizontal strata of sandstone and having a remarkably uniform altitude of 2,000 to 2,400 ft. The flat top of such a range is called a *chapada* or *taboleiro*, and its width in places is from 32 to 56 mi.

The boundary line with Piauí follows one of these ranges, the Serra Ibiapaba, which unites with another range on the southern boundary of the state known as the Serra do Araripe. Another range, or escarpment, crosses the state from east to west, but is broken into two principal divisions, each having several local names. These ranges are not continuous, the breaking down of the ancient plateau having been irregular and uneven. The higher ranges intercept considerable moisture from the southeast trade winds, and their flanks and valleys are covered with forest, but the plateaus are either thinly wooded or open campo. These upland forests are of a scrubby character and are called *caatingas*.

The sandy, coastal plain, with a width of 12 to 18 mi., is nearly bare of vegetation; behind there is a more elevated region with broken surfaces and sandy soil which is amenable to cultivation and produces fruit, cotton and most tropical products when conditions are favourable. The rivers of the state are small and, with one or two exceptions, become completely dry in the dry season. The largest is the Jaguaribe, which flows entirely across the state in a northeast direction with an estimated length of 210 to 465 mi. The year is divided into a rainy and dry season, the rains generally beginning in October and lasting until December. The soil of the interior is thin and porous and does not retain moisture; consequently the long, dry season turns this part of the country into a barren waste, relieved only by vegetation along the river courses and mountain ranges and by the hardy, widely distributed carnauba palm (*Copernicia cerifera*), which in places forms groves of considerable extent. Sometimes the rains fail altogether, and then a drought (*sêca*) ensues, causing famine and pestilence throughout the entire region. The most destructive droughts recorded were those of 1711, 1723, 1777–78, 1790, 1825, 1844–45 and 1877–79, the last-mentioned destroying nearly all the livestock in the state and causing through starvation and pestilence the deaths of nearly 500,000 persons—more than half the population—while thousands more were obliged to emigrate to other states.

There are two lines of railway running inland from the coast: the Baturité line from Fortaleza to Crato, in the southern part of the state, and to Patos in the state of Paraíba; and the Sobral line from Camocim to Crateús, about 210 mi. The railways were built by the national government after the drought of 1877–79 to give work to the starving refugees. Great dams are also being constructed and extensive irrigation systems laid out.

Only a very small percentage of the population, which numbered 2,735,702 (1950 census), is of European origin, the large majority being mestizos. There are few Negroes.

The state of Ceará became a bishopric of the Roman Catholic Church in 1853, the bishop having his residence at Fortaleza. The state is represented in the national congress by 3 senators and 17 deputies. The capital, Fortaleza, sometimes called Ceará, is the principal commercial centre and shipping port. Its population was 213,604 and that of the *município* was 280,084 in 1950. The principal towns are Aracati, Baturité, Acaraú, Crato, Maranguape and Sobral.

The territory of Ceará included three of the *capitanias* originally granted by the Portuguese crown in 1534. The first attempts to settle the territory failed, and the earliest Portuguese settlement was made near the mouth of the Rio Camocim in 1604. The French were already established on the coast, with their headquarters at St. Louis, now Maranhão. Ceará was occupied by the Dutch from 1637 to 1654, and became a dependency of Pernambuco in 1680; this relationship lasted until 1799, when the *capitania* of Ceará was made independent. The *capitania* became a province in 1822 under Dom Pedro I. A revolution followed in 1824, the president of the province was deposed 15 days after his arrival, and a republic was proclaimed. Internal dissensions broke out, the new president was assassinated, and after a brief reign of terror the province resumed its allegiance to the empire. Ceará was one of the first provinces of Brazil to abolish slavery.

CEAWLIN (d. 593), king of the West Saxons, included, in the *Anglo-Saxon Chronicle*, among the "Bretwaldas" or specially powerful kings, succeeded his father Cynric in 560. He took Silchester, and moving eastward Ceawlin and his brother Cutha defeated the forces of Aethelberht, king of Kent, at the battle of Wibbandun in 568. In 577 he led the West Saxons from Winchester towards the Severn valley; gained a victory over three British kings, Conmail, Condidan and Farinmail, at Deorham and added the district round Gloucester, Bath and Cirencester to his kingdom, thus isolating the Britons of Cornwall from those of Wales. A further advance was begun in 583. Uriconium, a town near the Wrekin, and Pengwyrn, the modern Shrewsbury, were destroyed, but Ceawlin was defeated by the Britons at Fethanleag or Faddiley, near Nantwich, and his progress was effectually checked. Internal strife among the West Saxons followed. In 591 Ceawlin lost the western part of his kingdom; in 592 he was defeated by his nephew, Ceolric, at Wanborough, driven from Wessex and was killed in 593.

See *Two of the Saxon Chronicles*, ed. by C. Plummer (Oxford, 1892); E. Guest, *Origines Celticae*, vol. ii (1883).

CEBES, the name of two Greek philosophers. (1) CEBES OF CYZICUS, mentioned in Athenaeus (iv, 156 D), seems to have been a Stoic, who lived during the reign of Marcus Aurelius. Some would attribute to him the *Tabula Cebetis* (*see* below), but as that work was well known in the time of Lucian, it is probably to be placed earlier. (2) CEBES OF THEBES, a disciple of Socrates and Philolaus. He is one of the speakers in the *Phaedo* of Plato, in which he is represented as an earnest seeker after virtue and truth, keen in argument and cautious in decision. Three dialogues, the Ἐβδόμη, the Φρύνιχος and the Πίναξ or *Tabula*, are ascribed to him by Suidas and Diogenes Laërtius. The two former are lost, and most scholars deny the authenticity of the *Tabula* on the ground of material and verbal anachronisms. They attribute it either to Cebes of Cyzicus (above) or to an anonymous author, of the 1st century A.D., who assumed the character of Cebes of Thebes. In the form of an interpretation of an allegorical picture in the temple of Cronus at Athens or Thebes, it develops the Platonic theory of pre-existence, and shows that true education consists in the formation of character.

The *Tabula* has been translated both into European languages and into Arabic (the latter published with the Greek text and Lat. trans. by Salmasius in 1640); Eng. trans. by H. E. Seebohm (Chipping Camden, 1906). It is usually printed together with Epictetus. Separate eds. by S. S. Jerram (with intro. and notes, 1878), C. Prächter (1893) and many others. *See* Zeller's *History of Greek Philosophy;* F. Klopfer, *De Cebetis Tabula* (1818–22); C. Prächter, *Cebetis Tabula quanam aetate conscripta esse videatur* (1885); R. T. Clark, *Characters of Theophrastus, etc.* (1909).

CEBU (Bisayan Sugbu), the second of the 21 chartered Philippine cities in rank of population, 167,411 in 1948 (an increase of 101,909 since 1918) is in the island province of Cebu, of which it is the capital and is on the east coast.

Cebu is one of the most historic points in the Philippines. A native village had long existed on the site of the present city when Magellan, commander of the first world encircling expedition, landed there on April 7, 1521. Opposite the site lies

Mactan Island (whose northwest shore forms the harbour's outer rim) where he met the native chief, Sicatuan, where each sealed a truce compact with his own blood and where, despite the compact, the great navigator lost his life. The image of Santo Niño (the Holy Child), now housed in the Augustinian church, is said to date from that period. The next distinguished foreign visitor was Miguel López de Legazpi, who arrived with some Augustinian friars, including Urdaneta, in 1565; and for the ensuing six years Cebu was the capital of whatever portion of the Philippines the Spaniards ruled. That distinction ceased with Legazpi's removal to what is now Manila; but Cebu has continued to be an important centre for the Bisayas, rivalled by Iloilo alone, which the former has now far outstripped. Toward the end of the 18th century the Roman Catholic cathedral was completed. Cebuanos took a prominent part in the insurrections against both Spain and the United States; but Cebu has profited immensely by the American occupation and its wide streets, motor roads, modern buildings and public school system are but a few of the results.

Cebu was open to foreign trade in 1863. It had long been a port of entry and its harbour is amply protected from the typhoons and baguios to which the region is subject. The city is also the principal one on the railway which skirts the province's eastern coast. An extensive maritime trade is carried on with Manila and Leyte, Bohol and the Negros provinces, Mindanao and elsewhere. The chief exports are abacá (Manila hemp), tobacco, sugar and copra. Manufactures of pottery, fabrics, sugar sacks and salt are carried on.

Cebu is a Roman Catholic Episcopal see and 137,555 of its adherents were reported from there in 1939. The bishop's palace, though small, is noted for its interior decorations. There were also reported from Cebu 2,971 members of the Independent Filipino Church, 2,139 Protestants, 1,262 Buddhists and several thousand of other, or no religious affiliation. Cebuano, the local Bisayan, is the vernacular. There is a provincial high school together with grade and parochial schools, a branch of the Philippine library and a meteorological station.

CECCO D'ASCOLI (1257–1327), the popular name of FRANCESCO DEGLI STABILI, a famous Italian encyclopaedist and poet—Cecco being the diminutive of Francesco, and Ascoli, in the marshes of Ancona, the place of his birth. In 1322 he was made professor of astrology at Bologna university, but, having written a commentary on the sphere of John de Sacrobosco (pub. Venice, 1518), in which he propounded daring theories concerning the agency of demons, he got into difficulties with the clerical party. He betook himself to Florence, where his attack on the *Commedia* of Dante, and the *Canzone d' Amore* of Guido Cavalcanti sealed his fate. He was burned at Florence in 1327.

His *Acerba* (from *acervus*), an encyclopaedic poem (best ed. Venice, 1510), consists of four books in *sesta rima,* treating in order of astronomy and meteorology, of stellar influences, of physiognomy, of the vices and virtues of minerals, of the love of animals, of moral, physical and theological problems.

See G. Castelli, *La Vita e le Opere di C. d'Ascoli* (Bologna, 1892), and C. Lozzi, *C. d'Ascoli* (1904).

CECIL, the name of a famous English family. This house, whose two branches hold each a marquessate, had a great statesman and administrator to establish and enrich it. The first Lord Burghley's many inquiries concerning the origin of his family created for it more than one splendid and improbable genealogy, although his grandfather is the first ascertained ancestor. In the latter half of the 15th century a family of yeomen or small gentry with the surname of Seyceld, whose descendants were accepted by Lord Burghley as his kinsmen, lived on their lands at Allt yr Ynys in Walterstone, a Herefordshire parish on the Welsh marches. Of the will of Richard ap Philip Seyceld of Allt yr Ynys, made in 1508, one David ap Richard Seyceld, apparently his younger son, was overseer. This David seems identical with David Cyssell, Scisseld or Cecill, a yeoman admitted in 1494 to the freedom of Stamford in Lincolnshire. At Stamford he prospered, being three times mayor and three times member of parliament for the borough, and he served as sheriff of Northamptonshire in 1532–33. Remaining in the service of Henry VIII. he was advanced to be yeoman of the chamber and sergeant-at-arms, being rewarded with several profitable leases and offices. By his first marriage David Cecil left at his death in 1536 a son and heir, Richard Cecil, who enjoyed a place at court as yeoman of the king's wardrobe under Henry VIII. and Edward VI. A gentleman of the privy chamber and sometime sheriff of Rutland, Richard Cecil had his share at the distribution of abbey lands, St. Michael's priory in Stamford being among the grants made to him. William Cecil, only son of Richard, was born, by his own account, in 1520, at Bourne in Lincolnshire. He advanced himself first in the service of the protector Somerset, after whose fall, his great abilities being necessary to the council, he was made a secretary of state and sworn of the privy council. In 1571 he was created Lord Burghley, and from 1572, when he was given the Garter, he was lord high treasurer and principal minister to Queen Elizabeth. By his first wife, Mary Cheke, sister of the scholar Sir John Cheke, tutor to Edward VI., he was father to Thomas, first earl of Exeter. By a second wife, Mildred Cooke, the most learned lady of her time, he had an only surviving son, Robert Cecil, ancestor of the house of Salisbury.

Created earl of Exeter by James I., the second Lord Burghley was more soldier than statesman, and from his death to the present day the elder line of the Cecils has taken small part in public affairs. William Cecil, 2nd earl of Exeter, took as his first wife the Lady Roos, daughter and heir of the 3rd earl of Rutland of the Manners family. The son of this marriage inherited the barony of Roos as heir general, and died as a Roman Catholic at Naples in 1618 leaving no issue. A third son of the 1st earl was Edward Cecil, a somewhat incompetent military commander, created in 1625 Lord Cecil of Putney and Viscount Wimbledon, titles that died with him in 1638, although he was thrice married. In 1801 a marquessate was given to the 10th earl of Exeter, the story of whose marriage with Sarah Hoggins, daughter of a Shropshire husbandman, has been refined by Tennyson into the romance of "The Lord of Burleigh." This elder line is still seated at Burghley, the great mansion built by their ancestor, the first lord.

The younger or Hatfield line was founded by Robert Cecil, the only surviving son of the great Burghley's second marriage. As a secretary of State he followed in his father's steps, and on the death of Elizabeth he may be said to have secured the accession of King James, who created him Lord Cecil of Essendine (1603), Viscount Cranborne (1604), and earl of Salisbury (1605). Forced by the king to exchange his house of Theobalds for Hatfield, he died in 1612, worn out with incessant labour; before he could inhabit the house which he built upon his new Hertfordshire estate. Of Burghley and his son Salisbury, "great ministers of state in the eyes of Christendom," Clarendon writes that "their wisdom and virtues died with them." The 2nd earl of Salisbury, "a man of no words, except in hunting and hawking," was at first remarked for his obsequiousness to the court party, but taking no part in the Civil War came at last to sit in the Protector's parliament. After the Restoration, Pepys saw him, old and discredited, at Hatfield, and notes him as "my simple Lord Salisbury." The 7th earl was created marquess of Salisbury in 1789.

Hatfield House, a great Jacobean mansion which has suffered much from restoration and rebuilding, contains in its library the famous series of state papers which passed through the hands of Burghley and his son Salisbury, invaluable sources for the history of their period. (O. B.)

(*See* also, EXETER, EARL, MARQUESS AND DUKE OF; members of the Cecil family separately mentioned are: BURGHLEY, WILLIAM CECIL; SALISBURY, ROBERT ARTHUR TALBOT GASCOGNE-CECIL, 3RD MARQUESS OF; SALISBURY, ROBERT CECIL, 1ST EARL OF; CECIL, HUGH RICHARD; CECIL OF CHELWOOD, 1ST VISCOUNT).

CECIL, HUGH RICHARD (BARON QUICKSWOOD) (1869–), English politician, youngest son of the 3rd Marquess of Salisbury, the prime minister, was born on Oct. 14, 1869, and was educated at Eton and University college, Oxford, where he obtained a first class in modern history in 1891, and was elected a fellow of Hertford college. He became one of his father's secretaries. He sat in the House of Commons as a Unionist for Greenwich (1895–1906), and for Oxford university from 1910 onward. He took a keen interest in church matters and was remarkable in debate for his oratorical powers and the loftiness of his ideals. In the stormy debates on the Balfour Education bill of 1902 he maintained that the only possible basis of general agreement was that every child should be brought up in the belief of its parents. He and Winston Churchill gathered round them, in the early years of the 20th century, a small group of young and able Con-

servative members, whose independent proceedings attracted some attention. He took a decided part in resisting tariff reform, and had no seat in the House between 1906 and 1910. He threw himself immediately and with passion into the struggle over the proposed curtailment of the powers of the House of Lords, and was active in resistance to the Parliament bill.

During the World War he joined the Flying Corps; he also served as a member of the commission that enquired into the Mesopotamia expedition. After the war he took a less active part in politics, but generally found himself in agreement with his brother, Lord Robert (later Lord Cecil of Chelwood), in adopting a more independent attitude toward the Coalition Government. With him, too, he supported the Enabling bill, and he became a prominent member of the Church Assembly set up in accordance with its provisions. In the conflict which arose over the Prayer Book Measure in 1928 he gave energetic support to the new proposals, both inside and out of the House of Commons. In 1936 he was appointed Provost of Eton, and resigned from parliament. He was created baron in 1941.

CECIL OF CHELWOOD, EDGAR ALGERNON ROBERT CECIL, 1ST VISCOUNT (1864–), British statesman, known before his elevation to the peerage as Lord Robert Cecil, third son of the third Marquess of Salisbury, was born on Sept. 14, 1864. He was educated at Eton and University college, Oxford, and was a prominent speaker at the Oxford Union. Lord Robert acted as one of his father's private secretaries from 1886 to 1888. He was called to the bar at the Inner Temple in 1887, and appeared in many important cases. He took silk in 1900.

In 1906 he entered parliament as Conservative member for East Marylebone, and he was one of the principal critics of Birrell's abortive education bill of that year. On many questions he took a heterodox position from the party point of view. In particular he dissociated himself from the tariff reform policy of Chamberlain, and thereby with Parliament from 1910 to 1911, when he was returned at a by-election for the Hitchin division of Herts, retaining this seat until his elevation to the peerage in 1923. He immediately resumed his old place as a powerful, though independent critic of Liberal policy, especially of the disestablishment of the church in Wales. He was one of the best friends of the women suffragists, and expressed the strongest disapprobation of the violent measures taken against them, though he did not palliate the offences against law and order of the extreme militants. Ultimately, after women had been granted the suffrage, he had the satisfaction of carrying a resolution "to amend the law with respect to the capacity of women to sit in Parliament" (Oct. 21, 1918).

Lord Robert was in office throughout the World War from the time that the Unionists associated themselves with the Government in May 1915 till the Armistice. As under-secretary for foreign affairs, then as minister of blockade and lastly as assistant secretary of State for foreign affairs, he was mainly concerned with the vital question of blockade. Lord Robert resigned at the general election of 1918 on the ground that he could not support the decision of the coalition Ministry to treat Welsh disestablishment as a *fait accompli*. Though no longer a minister of the crown, he nevertheless went over to Paris in 1919, where he served as chairman of the Supreme Economic Council, and played one of the principal parts, together with President Wilson and Gen. Smuts, in drafting the Covenant. After the peace he advocated increasingly full co-operation in the work of the League of Nations. In 1920 he attended the first Assembly of the League in Geneva as a representative of South Africa. In Parliament he steadily drifted into opposition to the coalition Ministry, and, though he did not form part of Bonar Law's Unionist Ministry in 1922, he joined Baldwin's first cabinet in May 1923 as Lord Privy Seal. He was raised to the peerage in Dec. 1923. He returned to office in Baldwin's second cabinet, in Nov. 1924, as chancellor of the duchy of Lancaster, and on several occasions acted as deputy for the foreign secretary, Sir Austen Chamberlain, on the Council of the League of Nations. As the principal British representative on the Disarmament Commission at Geneva in 1926–27 he found that his instructions necessitated a policy not in complete accordance with his convictions, and in 1927 he resigned his place in the Baldwin administration. President (1919–45) of the League of Nations Union, Lord Cecil remained, in face of the effects upon European and world affairs of German and Italian policy, uncompromisingly loyal to the League covenant. In 1937 he was awarded the Nobel peace prize.

CECILIA, SAINT (d. *c.* 176), patron saint of music and of the blind, is commemorated on Nov. 22. She was supposed to have been a noble Roman who with her husband and converts suffered martyrdom (*c.* 230), under the emperor Alexander Severus, but the researches of de Rossi (*Roma Sotteranea* ii. 147) confirm the statement of Fortunatus, bishop of Poitiers (d. 600), that she perished in Sicily under Marcus Aurelius (*c.* 176). The 4th century church at Rome in her honour was rebuilt by Pope Paschal I. (*c.* 820) and again in 1599. Cecilia, whose musical fame rests on a passing notice in her legend that she praised God by instrumental and vocal music, has inspired many a masterpiece in art, including the Raphael at Bologna, the Rubens in Berlin, the Domenichino in Paris, and in literature she is commemorated by Chaucer's "Seconde Nonnes Tale" and by Dryden's famous ode, set to music by Handel in 1736 and later by Sir Hubert Parry (1889).

Another St. Cecilia, who suffered in Africa in the persecution of Diocletian (303–304), is commemorated on Feb. 11.

U. Chevalier, *Répertoire des sources historiques* (1905), i. 826 f.

CECROPIA, in botany, a genus of trees (family Moraceae), native of tropical America. They are of rapid growth, affording a light wood used for making floats. *C. peltata* is the trumpet tree, so-called from the use of its hollow stems by the Uaupé Indians as a musical instrument. It is a tree reaching about 50ft. in height with a large spreading head, and deeply lobed leaves 12in. or more in diameter. The hollows of the stems and branches are inhabited by ants, which it has been claimed in return for the shelter thus afforded, and food in the form of succulent growths on the base of the leaf-stalks, repel the attacks of leaf-cutting ants which would otherwise strip the tree of its leaves. This is an instance of "myrmecophily," *i.e.*, a living together for mutual benefit of the ants and the plant.

CECROPS, traditionally the first king of Attica (Pausanias ix. 33). He was said to have divided the inhabitants into 12 communities, to have instituted the laws of marriage and property and a new form of worship. The introduction of bloodless sacrifice, the burial of the dead and the invention of writing were also attributed to him. He is said to have acted as umpire during the dispute of Poseidon and Athena for the possession of Attica. As one of the *autochthones* (*q.v.*) of Attica, Cecrops is represented as human in the upper part of his body, while the lower part is shaped like a dragon. Miss J. E. Harrison (in *Classical Review*, Jan. 1895) endeavours to show that Cecrops is the husband of Athena, identical with the snake-like Zeus Soter or Sosipolis, and the father of Erechtheus-Erichthonius.

CEDAR, a name applied to several coniferous trees (*see* Gymnosperms), and a few broad-leaved species.

Cedrus libani, the far-famed Cedar of Lebanon, is a tree which because of its beauty and stateliness has always been a favourite with poets and painters. It is frequently mentioned in the Scriptures as a symbol of power, prosperity and longevity. It grows to a height of from 50 to 80 ft. and at an elevation of about 6,000 ft. above sea-level. The bole of young trees is straight and upright and one or two leading branches usually rise above the rest. As the tree increases in size, however, the upper branches become mingled together to form a clump-headed crown. Numerous lateral ramifying branches spread, tier upon tier, in a horizontal direction from the main trunk and cover a compass of ground the diameter of which is often greater than the height of the tree. The branchlets of the cedar assume the same orientation as the branches, and the foliage is very dense. The tree is evergreen; new leaves are developed every spring, but their fall is gradual. In shape the leaves are straight, tapering, cylindrical and pointed, about 1 in. long, dark green and borne in spirally arranged tufts of about 30. The male and female flowers grow on

the same tree but on separate branches. The cones, borne on the upper side of the branches, are flattened at the ends and are 4 to 5 in. in length and 2 in. wide; they require two years to mature and while growing exude much resin. The scales are closely pressed to one another, reddish in colour, and at maturity fall away from the central axis. The seeds are provided with a long membranous wing. The root system is large and ramifying. This cedar, which flourishes best on sandy, loamy soils, appears in great numbers on Mt. Lebanon, chiefly on the western slopes, where it usually occurs in groves, some of which contain several thousand trees. There are also large forests on the higher slopes of the Taurus and Anti-Taurus mountains. The wood is fragrant, though not so strongly scented as that of the juniper or red cedar of America. It is generally reddish-brown, light and of a coarse grain and spongy texture, easy to work, but liable to shrink and warp.

Mountain-grown wood is harder, stronger, more durable and exhibits greater dimensional stability.

The Cedar of Lebanon is cultivated in Europe for ornament only. It thrives well in parks and gardens, but the young plants are unable to withstand great variations of temperature. The term *Eres* (cedar) of Scripture does not apply strictly to one kind of plant: the "cedars" for masts, mentioned in Ezek. xxvii. 5, must have been pine trees. Drawers of cedar or chips of the wood are now employed to protect furs and woollen stuffs from injury by moths. Cedar wood, however, is said to be injurious to natural history objects and to instruments placed in cabinets made of it, because the resinous matter in the wood acts as a corrosive.

The genus *Cedrus* contains two other closely allied species, namely, *C. deodara*, the deodar, or "god tree" of the Himalayas, and *C. atlantica*, the Atlas cedar of the Atlas range in north Africa.

The deodar forms forests on the mountains of Afghanistan, north Baluchistan and the northwest Himalayas at elevations of from 5,500 to 12,000 ft.; it may develop a clear bole of from 60 to 70 ft. under the crown. The wood is close-grained, long-fibred, scented and highly resinous and resists the action of water. The foliage is of a paler green, the leaves are slenderer and longer and the twigs are thinner than those of *C. libani*. The tree is employed for a variety of useful purposes, especially in building. It is cultivated in England and in California as an ornamental plant.

C. atlantica has shorter and denser leaves than *C. libani;* the leaves are glaucous, sometimes of a silvery whiteness, and the cones smaller than in the other two forms. Growth is somewhat more rapid than that of the ordinary cedar, but the tree produces a similar timber. It is found at altitudes of from 4,000 to 6,000 ft.

The name cedar is applied to species of several other genera of conifers, including *Juniperus, Thuja, Libocedrus, Chamaecyparis* and *Cupressus. Libocedrus decurrens*, of western North America, is known in the United States as incense cedar. *Chamaecyparis lawsoniana* is the Port Orford white cedar, a native of Oregon and California. The Bermuda cedar (*Juniperus bermudiana*) and the eastern red cedar (*J. virginiana*) are used in joinery and in the manufacture of pencils. Another species, the Atlantic white cedar (*Chamaecyparis thyoides*), is found in swamps along the southern coastal plains. The Spanish cedar is *Juniperus thurifera*, a native of the western Mediterranean region. Another species, *J. oxycedrus*, common in the Mediterranean region, forms a shrub or low tree with spreading branches and short, stiff, prickly leaves. A species of cypress, *Cupressus lusitanica*, naturalized in the neighbourhood of Cintra, is known as the Cedar of Goa. The genus *Widdringtonia* of tropical and South Africa is also known locally as cedar. The Japanese cedar (*Cryptomeria japonica*) is more closely related to the bald cypress. The family Meliaceae (which is entirely distinct from the conifers) includes, along with the mahoganies and other valuable timber trees, the Jamaica and the Australian red cedars, *Cedrela odorata* and *C. toona*, respectively. (E. S. Hr.)

CEDAR-BIRD or **CEDAR WAXWING:** *see* Waxwing.

CEDAR CITY, a city of Iron county, Utah, in the southwestern part of the state, at an elevation of 5,840 ft.; on federal highway 91, and the terminus of a branch line of the Union Pacific railway, constructed in 1923. The population was 6,172 in 1950 by the federal census. It is the largest city within a radius of 200 mi.; is surrounded by vast expanses of grazing country and potential agricultural land, with some 50,000ac. in irrigated farms, and by great deposits of iron, coal and gypsum; and is the gateway to the Zion National park, Bryce canyon, the north rim of the Grand canyon, Kaibab forest and Cedar Breaks. A Branch of the State agricultural college is situated here. In 1849 an exploring party sent out by Brigham Young discovered the beds of iron ore which gave the county its name. A volunteer company established a colony at Parowan, the county seat, in 1851. Cedar City was settled in 1851, and became the centre of the iron industry of that period, sending 12,500 lb. of pig-iron to Salt Lake City in the next eight years, besides manufacturing many articles of iron. With the development of rail transportation from the east the industry languished. In 1923 mining was begun on a large scale around Iron Springs, 10m. W. of Cedar City, and the present production (by stripping methods) is about 250,000 tons a year, averaging 53% in iron content.

CEDAR CREEK, a small branch of the North Fork of the Shenandoah river, Virginia (U.S.A.). It is known in American history as the scene of a memorable battle, which took place on Oct. 19, 1864, between the Union army under Gen. Sheridan and the Confederates under Gen. Early. (*See* Shenandoah Valley Campaigns.)

CEDAR FALLS, a city of Black Hawk county, Iowa, U.S.A., on the Cedar river, 100 mi. W. of Dubuque. It is on federal highways 20 and 218, and is served by the Rock Island, the Illinois Central, the Chicago Great Western and the Waterloo, Cedar Falls and Northern railways. The population in 1950 (federal census) was 14,336. More than 50 creameries are within a radius of 30 mi. The city is adjacent to the Josh Higgins state parkway. It utilizes its water power for sundry manufactures. It is the seat of the State Teachers college (established in 1876 as a normal school), which has a resident enrolment of more than 2,000.

Settlement began there in 1847. The town was laid out in 1851, and chartered as a city in 1865.

CEDAR RAPIDS, a city of Linn county, Iowa, U.S.A., on the Cedar river, in the east-central part of the state. It is on federal highways 30, 218 and 151; and is served by the Chicago, Milwaukee, St. Paul and Pacific, the Chicago and North Western, the Rock Island, the Illinois Central, the Cedar Rapids and Iowa City, the Waterloo, Cedar Falls and Northern railways and United Air Lines. The population was 72,149 in 1950; 62,120 in 1940; 56,097 in 1930; 45,566 in 1920 and 25,656 in 1900 by the federal census. The rapids in the river supply abundant water power, and the city ranks second in the state as a manufacturing centre, with an aggregate factory output valued at $200,000,000.

The leading products are cereals, corn products, meat packing, road building and mining machinery, farm hardware, ice cream machinery, radio transmitters, poultry and stock food, and milling. There is "Quaker Oats," the largest single unit cereal mill in the world. The city has an extensive jobbing business in all staple lines, and is the distributing centre for a rich agricultural district. Bank deposits in 1950 amounted to $120,622,869.

The city has an air of substantial prosperity. Its principal streets are 80 to 100 ft. wide, well paved and shaded. The assessed valuation of property in 1950 was $117,879,852. There are 23 fine parks, in one of which (Hawkeye Downs) an annual rodeo show is held.

One Bohemian periodical and one Swedish, with a substantial circulation, are published there. Coe college, a co-educational Presbyterian institution, which grew out of the Cedar Rapids Collegiate institute (1851), was chartered under its present name and opened in 1881. It has an enrolment of 800.

Cedar Rapids was settled in 1838; incorporated in 1856; and adopted a commission form of government in 1908.

CEDARTOWN, a city of Georgia, U.S., 62 mi. W.N.W. of Atlanta, served by the Central of Georgia and the Seaboard Air Line railways; the county seat of Polk county. Pop. (1950) 9,470.

There are important mineral deposits in the vicinity, especially of iron, manganese, marble and slate. Diesel railroad shops, cotton, and woollen mills, a tire cord fabric factory, etc., were established there.

The Big spring, on the ancient meeting ground of former Cherokee Indian inhabitants, flows at a rate of more than 5,000,000 gal. of pure water daily, and gives the city its entire supply of water. Cedartown was incorporated as a city in 1898.

CÉDULA, the Spanish form of the English word "schedule," of which *cedule* is an obsolete variant; in modern financial usage it refers more specifically to certain securities issued by the South American governments.

CEFALÙ (anc. CEPHALOEDIUM), a seaport and episcopal see of the province of Palermo, Sicily, 42 mi. E. of Palermo by rail. Pop. (1951) 11,813 (commune). The ancient town is named from the headland (Gr. Κεφαλή, head) upon which it stood (1,233 ft.); its fortifications extended to the shore, on the side where the modern town now is, in the form of two long walls protecting the port.

There are remains of a wall of massive rectangular blocks of stone at the modern Porta Garibaldi on the south.

It does not appear in history before 396 B.C., and seems to have owed its importance mainly to its naturally strong position. A small ancient building in good polygonal work (a style of construction very rare in Sicily) consists of a passage on each side of which a chamber opens. The doorways are of finely cut stone and of Greek type. On the summit of the promontory are extensive remains of a Saracenic castle.

The new town was founded at the foot of the mountain, by the shore, by Roger II in 1131, and the cathedral was begun in the same year. The exterior is largely decorated with interlacing pointed arches; the windows also are pointed. On each side of the façade is a massive tower of four stories. The roundheaded Norman portal is worthy of note. The interior was restored in 1559, though the pointed arches of the nave, borne by ancient granite columns, are still visible. The only mosaics preserved are those of the apse and the last bay of the choir; they are remarkably fine specimens of the art of the period (1148) and were carefully restored in 1859–62. Fine cloisters, coeval with the cathedral, adjoin it.

CEHEGÍN, a town of southeastern Spain, in the province of Murcia, on the right bank of the Arcos river, a small tributary of the Segura. Pop. (1950) (mun. 15,830). Cehegín is the market for local wine, olive oil and hemp and for marble and a little iron from the neighbouring hills.

Some of the older houses, the parish church and the convent of San Francisco, which contains still legible Roman inscriptions, are built of stone from the ruins of Begastri, a Roman colony which stood on an adjacent hill.

The name Cehegín is sometimes associated with that of the Zenaga, Senhaja or Senajeh, a North African tribe which invaded Spain in the 11th century.

CEILING, the overhead surface or surfaces covering a room; the underside of a floor or a roof; often used as a surface built to hide the floor and roof construction; the term is also employed, technically, for any finished boarding or sheathing and especially for a type of narrow, thin board, tongued and grooved, with a moulding on the edge.

Ceilings, in the larger sense of the word, have been favourite places for decoration from the earliest times, by painting the flat surface, as in the case of Egyptian tombs; by emphasizing the structural members of roof or floor, as in the beamed ceilings of the period of Francis I in France or the ceilings of Italian mediaeval churches (*e.g.*, S. Miniato at Florence); by treating it as a field for an over-all pattern of relief (*e.g.*, the earlier rooms of Hampton Court palace near London).

Of Greek ceilings little is known, except for some of marble, over temple porticoes, decorated with small, sunk panels or coffers, with moulded edges, and the field further decorated in polychrome. Roman ceilings were rich with relief and painting, as is evidenced by the vault soffits of Pompeian baths. Italian Renaissance architects found in similar examples inspiration for much of their most charming painted and relief decoration in stucco, and Robert Adam's 18th-century designs for ceilings ornamented with ovals, fans, hanging garlands, delicate scrolls and little painted panels have the same origin. The general Gothic tendency to use structural elements decoratively led to the rich development of the beamed ceiling, in which large cross girders support smaller floor beams at right angles to them, beams and girders being richly chamfered and moulded and often painted in bright colours (the Palazzo Davanzati in Florence contains numerous late 14th-century examples).

In the Renaissance, ceiling design was developed to its highest pitch of originality and variety. Three types were elaborated. The first is the coffered ceiling, in the complex design of which the Italian Renaissance architects far outdid their Roman prototypes. Circular, square, octagonal and L-shaped coffers, with their edges richly carved and the field of each coffer decorated with a rosette, abound. Occasionally pendants are found at the intersections (the Hall of the Two Hundred in the Palazzo Vecchio at Florence and various rooms of the ducal palace at Mantua are good examples). The second type consists of ceilings wholly or partly vaulted, often with arched intersections, with painted bands bringing out the architectural design and with pictures filling the remainder of the space, as in the loggia of the Farnesina villa in Rome, decorated by Raphael and Giulio Romano. In the baroque period, fantastic figures in heavy relief, scrolls, cartouches and garlands were also used to decorate ceilings of this type; *e.g.*, the Pitti palace, Florence; many French ceilings of the Louis XIV style are similar. In the third type, particularly characteristic of Venice (*e.g.*, the doge's palace), the ceiling became one large framed picture.

The early Renaissance saw in England another interesting development, that of plaster ceilings covered with an intricate pattern of intersecting curved lines, ornamented with foliage, grotesque animals and heraldic devices, and frequently accented by repeated large pendants; *e.g.*, Bramall hall; Hatfield house, London; Knowle; Sizergh. Later, the skilful English plaster workers were trained into a more classic vein, largely through the influence of Inigo Jones, who developed a type with large and deeply recessed panels, bold mouldings and bands of high-relief foliage and fruit, which remained fashionable for about a century after 1650.

In modern work the general tendency is toward simplified ceilings. Rich colour decoration is, however, sometimes found, especially in public buildings; an example in the United States is the Nebraska state capitol, designed by B. G. Goodhue, with ceilings by Hildreth Méière. (T. F. H.)

For the term "ceiling" as used in the science of the weather, *see* CLOUD and METEOROLOGY.

CELAENAE, an ancient city of Phrygia, situated on the great trade route to the east. It was the starting point of the march of Cyrus (401 B.C.) with the 10,000 against Artaxerxes. Its acropolis long held out against Alexander in 333 and surrendered to him at last by arrangement. Antigonus made it the capital of his kingdom; Antiochus of Syria, the son of Seleucus, refounded it on a more open site as Apameia (*q.v.*). West of the acropolis were the palace of Xerxes and the agora, in or near which is the cavern whence the Marsyas, one of the sources of the Maeander, issues.

See G. Weber, *Dineir-Celènes* (1892).

CELANDINE (*Chelidonium majus*), a common British plant, a member of the poppy family (Papaveraceae), an erect branched herb from 1 to 2 ft. high with a yellow juice, much-divided leaves and yellow flowers nearly an inch across, succeeded by a narrow, thin pod opening by a pair of fine valves, separating upward. The plant grows in waste places and hedgerows, and is probably an escape from cultivation. It has become widely naturalized in eastern North America, in open grounds, roadsides and in woods from Maine to Ontario and Illinois south-

ward to North Carolina. The lesser celandine is a species of *Ranunculus* (*R. Ficaria*), a small low-growing herb with smooth heart-shaped leaves and bright yellow flowers about an inch across, borne each on a stout stalk springing from a leaf-axil. It flowers in early spring, in pastures and waste-places. It is sparingly introduced into the United States from Massachusetts to Maryland.

GREATER CELANDINE, A YELLOW FLOWERED PLANT OF TEMPERATE REGIONS, SOMETIMES USED IN MEDICINE

CELANO, a town of the Abruzzi, Italy, province of Aquila, 73 mi. E. of Rome by rail. Pop. (1951) 12,686 (commune). It is on a hill above the Lago Fucino, and is dominated by a square castle, with round towers at the angles, erected in its present form in 1451. It contains three churches with 13th century façades in the style of those of Aquila. The origin of the town goes back to Lombard times, but it was destroyed in 1223, and rebuilt on a different site in 1227. It was damaged by the earthquake of 1915. It was the birthplace of Thomas of Celano, author of the *Dies Irae*, and biographer of S. Francis and S. Clara.

CELEBES, one of the four great Sunda Islands in Indonesia. It extends from 1° 45′ N. to 5° 37′ S. and from 118° 49′ E. to 125° 5′ E. From the backbone of the island, which runs north and south, three long peninsulas project north-east, east and south-east, respectively, the first being much the longest. These peninsulas form great gulfs—on the eastern side, from north to south they are: the Gulfs of Tomini, or Gorontalo, Tolo and Boni, the first being the largest. Thus the island is of very curious shape, and its length, 800 mi., and coastline, 2,000 mi., are quite disproportionate to its breadth, which averages between 36 and 120 mi., and at one point narrows to 18 mi. As a result, no place in Celebes is as far as 70 mi. from the sea. Celebes is situated in a very deep sea, between Borneo, west, which is in a shallow sea, on a shelf off the continent of Asia, and New Guinea, east, also in a shallow sea, and on a shelf projecting from Australia. The coast is dangerously fringed by drying coral reefs with many shoals and banks. The whole island is mountainous. Two parallel ranges run from north to south in the main central mass, and a northern extension of this traverses the entire northern arm of Celebes to Menado. From these ranges a single range projects north-eastwards to the extreme end of the eastern arm of the island, and two parallel ranges run, in a south-easterly direction, throughout the greater part of the south-eastern arm. The great central ranges (with Kamboeno, 9,678 ft., centre, and Piek van Bonthain, 9,419 ft., south) throw out large spurs, which dominate the central and western parts of Celebes. In the extreme north-east (Mt. Klabat, 6,545 ft.) and south the mountains are volcanic, some in the former region being active, while solfataras and hot springs are found in Minahasa. Wide rift valleys between the mountain ranges contain several lakes—in the north (Minahasa), Tondano, 2,000 ft. above sea level, 9 mi. long and 3½ mi. wide, (Gorontalo), Limboto, Batudaka, and Bolano Sawu, in the central nucleus, Lake Lindu, further south, in the same rift, Tempe and Sidenreng (monsoon lakes), and east of these, extending into the south-eastern arm, the principal lakes of the island—Poso, Matana and Towuti. They are very deep, Matana having been sounded to 1,500 ft. and Poso to 1,000 ft.

The rivers of Celebes are short and unimportant, for waterfalls and rapids are frequent; their mouths are obstructed by bars, and there is very little coastal plain, save at the head of the Gulf of Boni and near Macassar and among mangrove-swamps of the north coast of the Gulf of Tomini. The Jenemeja, which flows into the Gulf of Boni, is wide and navigable for some distance from its mouth, the Poso, which enters the Gulf of Tomini, is also wide and navigable, for very small craft, to Paluasi, the Sadang, entering the Gulf of Mandar, on the south-west coast, has many affluents, and is navigable by *sampans*, the Lasolo, south-east, admits steamers for 16 miles from its mouth; the rivers of Gorontalo are very small. The best natural harbours are Menado bay, Amurang bay, Kwandang bay, and Dondo bay, on the north coast; Tambu bay, Pare Pare bay, and Palu bay (Donggala), on the west coast; Gorontalo and Poso, in the Gulf of Tomini, with the Gulf of Poh, which penetrates eastward for 22 miles; the bays of Tomori, Kendari, and Staring, in the Gulf of Tolo, and the bays of Mengkoka, Palopo, Usu (Luwu), and Sopang, in the Gulf of Boni. Off the west coast is the Spermunde archipelago, a number of low islands surrounded by coral reefs; off the south coast, Saleyer; at the end of the south-eastern peninsula are several islands, of which the most important are Kabaena, Muna, Wowoni, and Buton (*q.v.*). They are separated from the peninsula by the straits of Tioro and Wowoni, both dangerous. The Banggai or Peling islands lie off the eastern extremity of Celebes, and though they belong politically to Ternate, geographically they resemble Celebes. In the Gulf of Tomini are the Schildpad islands, extending for nearly 80 miles east and west, the chief of them Talata Koh, Togian and Batu Daka, the Sangihe (Sangir) islands (*q.v.*), form the north-east extension of Celebes towards Mindanao, in the Philippines, which is continued by the Talaua group, north-east of these. With the adjacent islands, the area of Celebes is estimated at 77,855 sq.mi. and without them—72,986 sq.mi. The population of Celebes and the islands under its government, included in the residency of Menado, was, in 1930, 4,231,906.

Its situation between the two shelves of the Asian and Australian continents makes the geology of Celebes specially interesting. The broad central block is a complex of igneous rocks, with granite, gneiss, diorite and amphibolite characters, pierced in places by later eruptives, mostly Tertiary. This block is enclosed around its base by Cretaceous rocks, overlaid by Tertiaries and recent alluvial deposits towards the coasts. In the south-east corner of the block there is a broad band of pre-Tertiary tuffs, fringed occasionally by coral limestone. The northern part of the Gulf of Boni is widely bordered by Pleistocene and alluvial deposits, resting in the north-east upon late Tertiaries: a band of old plutonic rocks stretches from near Paloppo across the Gulf of Boni and the south-east peninsula to the Gulf of Tolo.

The meridional ridge of Celebes has an axis of crystalline schist, tourmaline quartzite, and glaucophane schist, penetrated and overlaid by andesite and basalt, flanked by tuffs, overlaid by late Tertiary *Orbitoides* limestone. The southern extension from the central block shows late Tertiary limestone, raised in parts, to a height of more than 3,000ft. and portions of the Archaean foundation are revealed. East of the central block is a faulted and depressed area of crystalline schists and metamorphosed shales, with gneiss and metamorphic limestones. The south-eastern and eastern peninsulas are, in the main, a broken crustal block with plutonic rocks. Metamorphics run southwards along the Gulf of Boni inland, a series of Pleistocene to recent rocks passes near to north of Muna island, with no Tertiaries except a small patch on Buton island. Around Mengkoka bay is a fringe of coral limestone, which borders Kabaena, covers more than two-thirds of Muna, all except the centre of Buton, and all of Wowoni, and the small islands north of it. There are indications of Jurassic rocks south of Lake Matana and metamorphics re-appear in Peling island. The north-eastern peninsula has northern and southern belts. The northern belt consists mostly of sedimentary rocks, Cretaceous or Tertiary, some altered by metamorphism. This belt runs parallel with the coast, and is separated by a parallel fault line from the southern belt, which consists of granites, gneisses, schists and intrusives, with Archaean schists and altered rocks, caught in faults: the valleys are filled with recent deposits.

Older rocks, Cretaceous and Tertiary, are preserved in occasional east and west bands, and in places near the south coast there are fringes of coral limestone. Minahasa is volcanic, and differs structurally from any other portion of Celebes.

The climate of Celebes is hot but is tempered by sea winds, which reach every part. Mean temperature ranges between 86° and 72°, with absolute extremes of 94° and 66°; it falls to below 50° at high altitudes on the mountains. At Palu, on the west coast, rainfall averages only 20.92 in., as compared with 116.11 at Macassar, while Menado and Gorontalo, both in the northeastern peninsula, average 106.48 in. and only 47.45 respectively. Macassar averages 132 rainy days annually; Palu only 77.

In the matter of fauna Celebes is the poorest island in the archipelago in the number of its species, yet among these it has animal forms which have no close allies in any other part of the world except in three of the neighbouring islands—Bachian, Buru and Sulu. Most interesting of these are the babirusa or pig deer, so named by the Malays from its long and slender legs and curved tusks, resembling horns; the black crested baboon (*Cynopithecus nigrescens*), akin to the African baboon; and the anoa, or dwarf buffalo, hunted extensively by the natives for its flesh. There are peculiar varieties of other indigenous animals, including five squirrels, a pig, a deer, two wood rats and two marsupials. Celebes has a number of peculiar species of parrots, woodpeckers, hawks, cuckoos, hornbills, starlings, flycatchers and pigeons; the brush turkey is found there. Crocodiles are common, there are snakes of various kinds, and many peculiar species of beetles and butterflies, while there is a distinct cleavage between the freshwater fishes of Borneo and Celebes. Although it has species which belong neither to the one nor to the other, the fauna of Celebes is more Asiatic than Australian, and the island is established as a transitional region between the oriental and Australian zoological regions. It is one of the oldest parts of the archipelago.

Much of Celebes is still covered with forest, especially around the Gulf of Tolo where it is almost primaeval and practically without tracks or clearings. The vegetation grows on the sides of precipitous and almost vertical mountain slopes, and the scenery is exceedingly varied and picturesque. "Nowhere in the archipelago," wrote A. R. Wallace, "have I seen such gorges, chasms and precipices as abound in the district of Maros; in many parts there are vertical or even over-hanging precipices five or six hundred feet high, yet completely clothed with a tapestry of vegetation." The rift valleys are extremely fertile, and there are extensive plateaus at varying heights where there is rich pastureland. The flora shows many resemblances to that of the Philippines, is more Indian in character in the west of the island and more Australian in the east, and while the trees of the lower slopes of the mountains differ strongly from those of Java and are smaller, the alpine flora is very similar. There are many kinds of palms—fanleaf, rattan, sago, *Arenga saccharifera*, which gives fibre for ropes, juice for sugar and a beverage known as sagueir; bamboo, breadfruit, tamarind and coconut trees flourish. Staple food crops grown are rice (mostly sawah) and maize; sugar cane, tobacco and vegetables are also raised. The chief commodity for export is copra, followed by corn, coffee, nutmegs, rubber and kapok; copal, damar and rattan are collected, also cattle horns and hides, for export. Fishing for turtles and mother-of-pearl is carried on extensively, and there is a trade in ebony, sandalwood and timber of other kinds. *Kayulara* and *Kolaka*, two kinds of timber almost impervious to attacks of the pileworm, are found in Celebes, and there is teak on the island of Muna. Gold occurs in Menado, and mines have been established there; nickel has been found and exploitation started in 1937. Iron, copper and lead exist and, in south Celebes, a little coal.

In Minahasa there are 105 people to the square mile, in other parts of Menado only 30 and, in the rest of the island and dependencies, 37. The coasts are generally well populated; there are large stretches of mountainous territory entirely uninhabited. There are at least six quite different native peoples of Celebes—the Toala, Toraja, Buginese, Macassars, Minahasese and Gorontalese. The first-named are found scattered all over the island, sometimes living in communities among other peoples, the result of having been enslaved by them originally. It is thought that they represent the true aborigines of Celebes. They are short and dark and have wavy or curly hair, a broad, flat nose, prominent mouth and receding chin. They are quite undeveloped and uncivilized, shy jungle dwellers, partly nomadic but quiet good-tempered people, and with a distinct language of their own. The Toraja are a collection of tribes, living in central, southeast and east Celebes. Living in isolated groups, in a very thinly populated country, they differ very much in development. Of Malayo-Polynesian stock, and divided into highland and lowland people, in some parts they intermingled with the Toala; in others they came under a Buginese and Macassarese civilizing influence. They are pagan (with an increasing Mohammedan element, however), are gradually giving up their fortified villages, in very inaccessible positions, for neat little settlements of houses standing each in its own garden, and they are becoming reconciled to the government's prohibition of head-hunting and of divination by spear throwing, but they are unclean and short-lived. The mountain peoples are more strongly built than those of the plains, with more prominent cheekbones, thinner lips and smaller eyes. Both have large mouths, thick lips and, usually, a broad nose, skin varying from light to dark brown and smooth, black hair, worn long. The women work harder than the men. Courteous and good-tempered when their confidence has been gained, they are agriculturists with only a few industries such as plaiting, pottery, wood carving and ironworking. Bark clothing is worn in remote districts, and Malayan style cotton garments where there is contact with more advanced cultures; many ornaments are worn and teeth are filed. Society is organized on the family basis, and the tribe is an extension of the family, a man choosing a wife from another branch of his own family. There are no social distinctions or tribal chiefs and woman has, comparatively, a high position among the Toraja, being able to choose her own husband. They collect forest produce and grow rice, possess their own language, with many dialects, and Christian schools have been well received by them. The Buginese and Macassars, probably of Toraja descent, came into touch with Hindu culture in southern Celebes, their home, and later were converted to Islam. They are now all Mohammedans, but with traces of Hinduism and paganism. Well built, fairly light skinned and energetic, they are very keen traders, proud, passionate and vindictive, devoted to feasting, gambling and cockfighting. As shipbuilders and seafarers they are unsurpassed in the archipelago; their excellent prahus are to be found everywhere in Malayan seas.

Society is both endogamic and exogamic, with survivals of a matriarchate, but Mohammedan law and customs are displacing all others. Both peoples are abstemious, feed chiefly on rice, maize and fish, eating buffalo flesh on festive occasions only; clothing is Malayan in style. They are extremely industrious, but their industries are not in a high state of development. Weaving is one of the chief, cotton sarongs of fine material being exported in large numbers from Mandar. Plaited goods of superior quality are made in Boni, gold- and silversmiths are mostly in Macassar, Gowa, Mandar and Boni, ironworkers in Luwu, Laiwui and Mandar, while shipbuilders flourish in Pambauwang, the Bira regency and elsewhere. Forest produce is collected, buffaloes, cattle and horses are kept, hunting and fishing are indulged in, for pleasure and as a means of livelihood, and their sea-carrying trade thrived in spite of steamship competition. A peculiar written alphabet, shared by Buginese and Macassars, is used also by some of the tribes of northern Celebes and by people of Sumbawa. The Macassar language and Buginese, to which it is nearly allied, belong to the Malayo-Javanese group. Arabic letters are being used for religious literature, and books in Arabic are read. There is a slight native literature, historical, legal, epistolary, and poetical. The Buginese and Macassars, like other groups in Celebes and throughout the archipelago, began to adopt Malay as a lingua franca and were encouraged therein by Dutch authority. The Minahasese are quite distinct in type from the other inhabitants of Celebes, they are closely related to the people of the islands of Siau and Sangi, and are probably part of an immigrant race from the north which settled there, and in the Philippines, of partly Cau-

casian type. They have a very light skin (some of the women have red cheeks and lips), lighter than any other race in the Archipelago, high nose, prominent lips, eyes widely separated, stiff, short, black hair and pleasant features, and they are tall and strong. Like the Maoris, a few generations back they were a savage, warlike race, constantly engaged in raids and head-hunting. European influence has completely eliminated this, and today the Minahasese are Christian, live in European style (each village has its church and school), are cleanly, sober and industrious, make good soldiers, being used extensively in the Dutch Colonial army and police, and compete successfully with Amboinese and Eurasians as clerks, schoolmasters, etc. They have a native tongue, but Malay and Dutch are superseding it. Their territory proper is in the extreme north and northeast, cultivation (coffee, coco-nuts and spices are grown largely), is in the European style, and their numbers do not exceed 300,000. The Gorontalese, who live in the west and south of the northeastern peninsula, are of the Toraja family, not related to the Minahasese, and largely Mohammedan, a short, smooth-haired, and rather light-skinned people, with a marked difference between the people of the coast and inland. They are agriculturists (rice, maize, coco-nuts and tobacco are grown), forest products collected, and weaving and plaiting are carried on, some of the finest materials in Celebes being produced.

They are neither strong nor very industrious; preponderance of women has encouraged extensive polygamy. In numbers they are estimated at about 223,000. Pagan (inland) and Mohammedan coastal tribes live on Banggai and Peleng.

For administrative purposes Celebes is divided into two separate divisions—the residency of Celebes, with dependencies (southeastern, southern peninsulas and islands, and the west coast), and the residency of Menado (the northeastern peninsula and the coast of the Gulf of Tomini—including the Banggai Islands).

The population of Celebes and dependencies is 3,093,251, composed of 4,537 Europeans and Eurasians, 25,497 foreign Asiatics, including Chinese and Arabs, and 3,063,217 natives. The population is much larger on the coasts than inland. The chief port and trade centre and the seat of the resident is Macassar (*q.v.*), with a population of 84,855 (3,447 Europeans included). All the other towns of any importance of Celebes, quite small in comparison with Macassar, are on the coast; for communications hardly exist inland, although the whole country is under direct Dutch rule, with some modification in a few districts of Menado and in the two small states of Luwu and Wajo, where the "short declaration" applies. Authority is enforced by officials on tour and just suffices to pave the way for civilization. Bonthain, on the south coast, is a small port and trade centre (population 6,711); such, also, are Pare Pare, Mamudyu and Madyene on the west coast. On the Gulf of Boni are Kajang, Palima, Desu Bay, Palopo and Kolaka, and on the east coast and Gulf of Tolo—Kendari, Salabanka, Bunku, Koloneday and Luwuk, and on the southern shore of the Gulf of Tomini—Pagimana, Bunta, Posso and Parigi. Some of these places are very small, but all are ordinarily ports of call for ships of the Royal Packet Navigation company and trade centres, zones of collection for great tracts of the hinterland. The residency of Menado has a population of 1,138,655, including 3,146 Europeans and Eurasians, and 25,123 foreign Asiatics. The chief port and centre of administration is Menado, in the extreme northeast, on Menado bay, with a population of 27,544. Unlike the rest of Celebes, Menado has centres of population inland, on plateaus among the mountains, and of these Tondano (2,000 ft.), near the lake and river of the same name, is the chief, with a population of 15,007. It has a cool, refreshing climate, and, situated amid beautiful mountain scenery, is quite a health resort. A pretty little town near by is Tomohon, a few hundred feet higher, which has a training school for native girls and a training college for native preachers, and a wireless station. Gorontalo, on the south coast of the peninsula, is a very important port and trade centre. It has an excellent harbour, with a magnificent approach, mountain ridges, thickly clad with vegetation running down to the shore, on either side of the narrow Gorontalo bay. (Lake Limboto is not far distant.) It has a population of 15,603, does a busy trade in copra, coffee and other products, and, like Menado, is in direct touch with ports in Java, Singapore and other large ports. Small ports on the north coast are Amurang, on the bay of that name, and with a safe anchorage in all weathers, Kwandang, on Kwandang bay, having ruins of an old fort, and Palehleh, a centre for the gold-mining district, near by; on the southeast coast are Kema, Buna and Jikol; on the west coast lies the port of Donggala (pop 3,821), the seat of an assistant resident. Service was suspended some years ago on a short tramway (28.7 mi. long), from Macassar to Takalar. Sea transport provides the principal, and in most parts, the only means of communication, though motor roads exist in Menado and southern Celebes. Macassar has cable communication with Java, Menado with Borneo, and Gorontalo with Ternate (Moluccas); there is a telegraph line between Amurang and Menado; and Macassar, Menado and Gorontalo have telephone systems. Imports and exports were respectively, in 1939, for Menado 3,280,000 and 5,176,000 guilders, and for Celebes and dependencies 16,028,000 and 17,057,000 guilders.

The Portuguese appear to have discovered and established some influence in Celebes in 1512 when they were monopolizing the spice trade of the Moluccas. The sultan of Macassar, as head of the state of Gowa (southwestern Celebes) favoured the Portuguese and the English, who later attempted to get a footing in Celebes. This annoyed the Dutch, who defeated the sultan early in the 17th century, though the Portuguese helped him. In 1607 a Dutch settlement at Macassar began to establish a firm trade footing in southern Celebes. The Dutch then used the sultan to check the power of Ternate in the Moluccas, and with their friendship he was able to subdue Boni, a rival state in southeast Celebes, and to hold Luwu, but he grew too powerful, and the Dutch (1654) conquered the island of Tidore in spite of a Macassarese fleet. War with Gowa, interrupted only by indecisive treaties, lasted till 1667, when the Dutch Admiral Speelman crushed Gowa and the Macassarese, with help from Boni, and imposed the Bongay treaty. Gowa abandoned all claims to supremacy, surrendered lands to the Dutch East India company, left to it trade monopoly, and fell into decay. Boni's growth in power led the Dutch later to protect the independence of Gowa but the Dutch used their Buginese allies of Boni in the early wars in Java, and during the British occupation of Java, Raffles had to send an expedition to Celebes against the unruly Buginese in Boni. When Dutch power in Java was restored, a Dutch expedition had to be sent to Boni; but it was not until 1848 that Boni submitted to the Bongay treaty in a revised form. The treaty was not kept and a second expedition, in 1859, made Boni a fief of the Netherlands government, while part of its territory was ceded to the Dutch. The last prince, La Pawowoni Kraeng Segeri, refused in 1905 to pay certain dues and interfered with other states, and he was banished, and Boni then lost its independence completely. About the same time Gowa interfered in another part of Celebes. The Dutch sent troops and in 1911, Gowa, too, was incorporated in Dutch territory. The state of Luwu signed the Bongay treaty in 1667, but it was not until after the Boni War, in 1861, that the Dutch succeeded in establishing any real influence there and there was some trouble in 1886 over the refusal of Luwu to pay a fine for the murder of some shipwrecked sailors on its coast; but in 1905 it agreed to abide by the "short declaration," which then was also applied to the state of Wajo, likewise a signatory of the Bongay treaty, but which had at times been in open revolt, often in trouble with Boni, and had experienced serious internal disorder as recently as 1902. Menado was first colonized by the Spaniards, on the northern coast, and settlers were attracted from neighbouring islands. The sultan of Ternate also claimed suzerainty over it, and fairly early in the 17th century the Dutch entered into relations with the natives of the country to protect them from both Spaniards and Ternate. In 1657 the present capital and fort were built, at Menado, and a trade agreement was signed for the delivery of a certain amount of ironwood annually. In 1677 the Sangi and Talaua islands, and later, certain small kingdoms on the north coast, were placed under the rule of the Dutch governor of Ter-

nate, and from that time onwards Dutch influence expanded, until the conquest of the East Indies by the Japanese during World War II. Japan landed troops at the northern tip of the Celebes Jan. 11, 1942, and within a month controlled most of the island except the remote interior areas.

CELERY (*Apium graveolens*), a biennial plant (fam. Umbelliferae) which, in its wild state, occurs in England by the sides of ditches and in marshy places, especially near the sea, producing a furrowed stalk and compound leaves with wedge-shaped leaflets, the whole plant having a coarse, rank taste and a peculiar smell. It is also widely distributed in the north temperate region of the old world. By improvement through breeding and selection and blanching, the stalks lose their acrid qualities and assume the mild sweetish aromatic taste peculiar to celery as a salad plant. A large number of varieties are cultivated by gardeners, which are ranged under three classes, green, white and red—the improved green varieties being generally the best flavoured and most crisp and tender. Red varieties are little known in the United States. Both blanched and green it is stewed and used in soups. In the south of Europe celery is much used in its natural condition. In the United States approximately 590,000 tons annually were grown commercially in 1940 and 1941. It was grown most extensively in California, Florida, Michigan and New York, in the order named, at that time.

Celeriac, or turnip-rooted celery (*Apium graveolens,* var. rapaceum), is a variety cultivated more for its roots than for the stalks, although both are edible. It is chiefly grown in northern Europe. (V. R. B.)

CÉLESTE, MADAME (1815–1882), French dancer and actress, was born in Paris on Aug. 16, 1815. As a little girl she was a pupil in the ballet class at the Opéra, and made her début at the Bowery theatre, New York city, at 15. In England in 1837 she gave up dancing, and appeared as an actress. In 1844 she joined Benjamin Webster in the management of the Adelphi, and afterwards took the sole management of the Lyceum till 1861. She retired in 1870. She died in Paris on Feb. 12, 1882.

CELESTIAL MECHANICS is the branch of astronomy that deals with the mathematical theory of the motions of celestial bodies. The foundation was laid by Sir Isaac Newton by the publication in 1687 of his *Philosophiae Naturalis Principia Mathematica,* usually referred to as the *Principia.* Here he published the three laws of motion which express the principles of mechanics, consolidating progress begun with the pioneer work of Galileo Galilei earlier in the 17th century. Newton also formulated the universal law of gravitation which states that any two particles of mass in the universe attract each other with a force that varies directly as the product of the masses and inversely as the square of the distance between them. These foundations permit the statement of a problem in celestial mechanics in the form of a set of equations of motion, ordinary differential equations of the second order. A proper understanding of the subject requires knowledge of this branch of mathematics.

An important triumph of Newton's was that Kepler's three laws of planetary motion, which had been derived empirically by Johann Kepler, were obtained as a consequence of the law of gravitation in conjunction with the laws of motion, applied to the problem of two bodies (*see* ORBIT, in which basic technical terms used in this article are defined). The next in order of difficulty is the case in which three bodies are considered, the famous problem of three bodies. The solar system, consisting of the sun and nine known principal planets, all but three surrounded by one or more satellites, constitutes a problem of many bodies. The significant circumstance that the mass of the sun is about 1,000 times that of the most massive planet, Jupiter, makes the sun's gravitational attraction far outweigh the mutual attractions of the planets. This suggests a process of successive approximations that has become the standard procedure in the mathematical theory of planetary motion, the deviations from elliptic motion being called the perturbations. In the case of the moon's motion the earth produces the principal attraction. Notwithstanding the very great mass of the sun, the effect of the sun's attraction is a small fraction of that of the earth owing to the close proximity of the latter. However, in the case of some satellites the perturbations produced by the sun's attraction may reach very sizable amounts. The mutual attractions of the component stars in triple and quadruple systems of stars suggest other interesting problems in celestial mechanics. In all known cases the configuration is always similar to that of the sun-earth-moon system, and methods similar to those employed in the study of satellite motion may be used. In part because of observational difficulties this field is not as far advanced as the study of motions in the solar system.

During the 18th century powerful analytical methods, made possible by the development of differential and integral calculus, were applied to the problems of celestial mechanics. These methods were generally successful in accounting for the observed motions of bodies in the solar system, and for more than 200 years this success built up a high degree of confidence in Newtonian mechanics and Newton's law of gravitation. This attitude was well expressed by J. H. Poincaré who wrote, in 1892, that ". . . the ultimate aim of celestial mechanics is to solve the great problem of knowing whether Newton's law alone explains all astronomical phenomena." On account of the necessary introduction of the theory of relativity the statement would require modification.

Relativity Effects.—It is now recognized that the Newtonian laws of motion and law of gravitation are approximations to the true laws governing the motions of celestial bodies (*see* RELATIVITY). It has been found, however, that the relativity effects, *i.e.,* the deviations from the motions derived on the basis of the classical Newtonian theory, are exceedingly small in all astronomical problems. In the motion of the perihelion of the innermost planet, Mercury, and in a very few other cases, they are large enough to be revealed by the most precise observations. A comparison between observations and theory, in which the perturbations are properly taken into account, confirms the excess of the motion of the perihelion in the amount of 43 seconds of arc per century, as required by the theory of relativity. This is one of the most convincing observational proofs of the theory of relativity. The effect diminishes rapidly for planets at a greater distance from the sun. In the case of the earth the relativity advance of the perihelion is about 4 seconds of arc per century, just large enough to be confirmed by the observations. On account of the smallness of the relativity effects in problems in celestial mechanics the justified procedure is to continue the use of the equations of motion following from the classical theory, and to apply the small relativity corrections, if at all necessary, in a minor adjustment of the results.

Gravitational Attraction of Finite Bodies.—The Newtonian law of gravitation is stated for particles, not for bodies of finite extent. It was shown by Newton that bodies the masses of which are arranged with perfect spherical symmetry attract each other in accordance with the law of gravitation as if the masses were concentrated in the centres of the respective spheres. It is found that the effect of nonsphericity diminishes rapidly with the distance between the bodies. Hence in the solar system in which the principal bodies are all nearly spherical and the distances, as a rule, large compared with the dimensions of the bodies, it is in many cases permissible to treat the planets and satellites as point-masses. Some interesting exceptions exist: the innermost satellite of Jupiter's system revolves in an orbit the radius of which is only 2½ times the radius of the planet. Owing to its rapid rotation the planet is flattened, and its gravitational attraction differs appreciably from that of a spherical body of the same mass. The principal effect upon the motion of the satellite is an advance of the perijove and a backward motion of the node, both at the rate of 2½ revolutions a year. The innermost satellite of Saturn shows a similar effect with a rate of one revolution a year. These are extraordinary cases; in most satellite orbits the resulting effect is small.

Other Branches of the Subject.—A related branch of celes-

tial mechanics is the gravitational theory of rotating liquid or gaseous masses with applications to the earth and the other larger planets. Astrophysical applications to close double stars have become increasingly important (*see* GEODESY and PRECESSION OF THE EQUINOXES). Newton explained the ocean tides as caused by the gravitational attraction of the moon and the sun. Sir George Howard Darwin, in addition to developing modern methods of tidal analysis and tidal prediction, also treated the cosmogonic aspect of tidal theory in his work on the development of the earth-moon system (*see* TIDES).

The various subjects described are recognized branches of celestial mechanics, which may be understood to embrace all of gravitational astronomy. The central problem, however, remains that of the mutual attractions among three or more bodies, each treated as a point-mass. There are two distinct approaches to the subject. The astronomer is forced to use methods that lead to a practical solution, even if they have the defect that the representation of the motion is valid for a limited interval of time only. The mathematician insists on using only processes of unquestionable validity, and is not primarily concerned with the astronomical requirements. Both points of view are meritorious, and each has had effects upon the development of the other.

Planetary Theory.—An important method for the treatment of planetary perturbations was introduced by Joseph Louis Lagrange (1736–1813). In an elliptic orbit the six orbital elements have constant values, completely determined by the three co-ordinates and the three components of the velocity at any time. Since the attractions by other planets cause a planet to follow a path differing from a fixed ellipse, the elements of its orbit so determined will necessarily vary with the time. Hence one may describe the "perturbed" orbit of a planet by giving the elements as functions of the time. Lagrange's method provides a process for deriving analytical expressions for the derivatives of the varying elements. These expressions are rigorous, but their integration requires the introduction of a process of successive approximations. The ordinary procedure gives rise to the presence of terms proportional to the time, in addition to periodic terms, in the final expressions for the elements. The terms proportional to the time, t, are called secular terms. Their presence raises such questions as whether the eccentricity of a planetary orbit may increase indefinitely, endangering the stability of the planetary system. Such a conclusion would be very superficial. The terms obtained in further approximations, having higher powers of t as factor, will modify the terms obtained in the earlier approximations in a manner that cannot be foreseen without appropriate mathematical analysis.

The integration of the periodic terms introduces divisors of the form $kn+k'n'$, in which n, n' are the mean motions of the two planets, and k, k' integers, both positive and negative. In the mean longitude the squares of these divisors occur. Whatever the mean motions, there will always be linear combinations $kn+k'n'$, small compared with either of the mean motions, n or n'. Such small divisors cause large coefficients in long-period terms, with the principal effect in the mean longitude. The motions of the planets Jupiter and Saturn furnish one of the most interesting illustrations of the effects of small divisors. The annual motions of the two planets are very nearly in ratio 5 to 2, which produces a long-period term with period of about 900 years. The amplitude of the perturbation in the mean longitude is 1,196 seconds of arc in Jupiter and 2,908 seconds of arc in Saturn. These are "the great inequalities" in the motions of these planets the cause of which was discovered by Laplace in 1786. The small divisors in celestial mechanics are related to the more general problem of resonance in mechanical systems.

A more direct approach to the solution of the perturbation problem is that in which the perturbations in the co-ordinates are obtained directly. Among the methods of this type that were employed with success may be mentioned those of Pierre Simon de Laplace and of Simon Newcomb. The apparent advantages are largely cancelled, however, in cases of planetary motion in which large perturbations due to small divisors are an important feature. In such cases a method in which the mean longitude is obtained has decided advantages. By an ingenious procedure, P. A. Hansen succeeded in deriving a method that combines the advantages of the two solutions of the perturbation problem. This method has been tested in numerous applications, and was chosen by G. W. Hill for his theory of Jupiter and Saturn, the most difficult problem among the principal planets.

An accomplishment that demonstrated strikingly the power of the theory of planetary motions was the discovery of the planet Neptune in 1846. Its presence and location in the sky had been predicted with astonishing accuracy by J. C. Adams and by U. J. J. Leverrier from deviations in the motion of the planet Uranus (*see* NEPTUNE). Attempts were made to discover planets beyond Neptune by a similar procedure, but the discovery of Pluto at the Lowell observatory in 1930 must be ascribed to perseverance in systematic search rather than accuracy of prediction by mathematical theory.

Secular Variations.—Planetary theories of the types described are entirely satisfactory for the immediate purposes of astronomy; the construction of tables that represent the motion of a planet for a limited time, say, a few thousand years. For questions concerning the stability of the solar system or, generally, its configuration in the very distant past and future such representations of planetary motion are insufficient. The question arose whether the secular terms occurring in planetary theories could be avoided. Lagrange obtained a solution in which he ignored the periodic terms. Retaining only the terms of the lowest power in the elements he obtained for the variation of the elements two sets of linear differential equations with constant coefficients, the eccentricity and perihelion appearing in one set, the inclination and node in the other. For the principal planets of the solar system, excluding Pluto, these equations have been solved in closed trigonometric form. In a solution of this type one obtains for the eccentricity and perihelion of each planet expressions containing eight trigonometric terms, the separate terms constituting oscillations with periods ranging from 57,000 years to 2,100,000 years. Similar expressions are obtained for the elements defining the positions of the orbital planes in space. These results give at least some indication of the long-period fluctuations in the elements of the planetary orbits. They should, however, be applied with caution. Further approximations present the same difficulty of small divisors as is met in the case of the periodic perturbations of the ordinary planetary theory. A still outstanding problem is the inclusion of Pluto in the solution of the secular variations. This will require a novel approach since the ordinary procedure leads to divergent developments.

The asteroids or minor planets furnish a rich field of application of the processes of celestial mechanics. The existence of the gaps in the ring of asteroids leads to the difficult theory of resonance in planetary motion. The application of the theory of secular variations led K. Hirayama to the discovery of five families of minor planets. He concluded that the members of each family must be fragments of a larger parent body. F. L. Whipple established a similar relationship between the orbit of Encke's comet and the orbits of certain meteors determined from trails on photographic plates obtained at the Harvard observatory (*see* MINOR PLANETS).

Satellite Motion.—A common feature of all satellite problems is that the motion proceeds at a much more rapid rate than among planetary orbits. In the moon's motion the line of apsides goes through a revolution in about nine years, the node in 19 years. These periods should be compared with the periods of tens or hundreds of thousands of years that affect the motions of the perihelia and nodes of planetary orbits. Consequently, in a satellite theory one cannot permit the appearance of the time in the coefficients of perturbation terms in the manner in which they are tolerated in planetary theories. One must aim at expressions free from this defect. The most complete solution of a satellite problem is the lunar theory (*see* MOON). Elaborate investigations have also been devoted to the satellite systems of Jupiter and Saturn. These systems present cases of resonance that are among the more interesting problems of celestial mechanics.

Modern Methods.—From the time of Lagrange until the present mathematical astronomers have made attempts to introduce the more perfect methods used in the lunar theory into the problem of planetary motion. A method similar to that used by Charles Eugène Delaunay in the lunar theory has been applied to planetary problems, but its application to the entire system of principal planets would be exceedingly laborious.

G. W. Hill opened up a new approach to problems in celestial mechanics by his use of a periodic orbit as a first approximation to the lunar theory. This subject was very fully investigated by J. H. Poincaré, whose work has led to a clearer understanding of the mathematical questions involved. Principally because of his work it is now recognized that, from a mathematical point of view, even such perfect developments as the lunar theories by Delaunay and by Brown leave something to be desired.

On account of the analytical difficulty of many problems in celestial mechanics investigators have resorted to the method of numerical integration. The method is used extensively for calculating the motions of asteroids and comets, and also in mathematical researches in the problem of three bodies.

The General Problem of Three Bodies.—This problem possesses ten known integrals, all of an algebraic character. Such an integral is a function of the co-ordinates and momenta of the three bodies that remains constant throughout the motion. The original equations of the problem form a system of the 18th order, nine differential equations of the second order. With the aid of the ten integrals, the "elimination of the nodes" and the elimination of the time the system may be reduced to one of the sixth order. This reduction was actually made by Lagrange and improved by later authors by the use of the canonical form of the equations. The reduction of the problem of three bodies with the aid of known integrals suggested that, if additional integrals were discovered, the problem might be further reduced and even completely solved. All such attempts failed; finally H. Bruns, in 1887, proved that no further algebraic integrals of the three-body problem exist. Soon afterward Poincaré proved that no further integrals uniform with respect to the elliptic elements exist. This result is of the greatest importance since it proves that the developments in trigonometric series used in the astronomical methods cannot converge for all values of the constants within a finite range. It does not exclude such a representation in the case of particular orbits; obvious examples are furnished by the periodic solutions and by the particular solutions which were first studied by Lagrange (*see* TROJAN PLANETS).

The simplified problem in which one of the three bodies has negligible mass and moves in the orbital plane of the two massive bodies, which are supposed to move in circular orbits, is the so-called restricted problem. The system of equations is one of the fourth order with one known integral, the Jacobian integral. Let $1-m$ and m be the masses of the finite bodies; r, r_1, r_2, the distances of the infinitesimal mass from the centre of the mass and the two bodies respectively, and V the velocity of the infinitesimal mass in a co-ordinate system the origin of which is at the centre of mass, and which rotates uniformly with the period of revolution of the finite masses. The Jacobian integral, if the units of time and distance are conveniently chosen, is then

$$r^2 + \frac{2(1-m)}{r_1} + \frac{2m}{r_2} = V^2 + C,$$

C being an arbitrary constant. By putting $V^2=0$ one obtains a single family of curves with C as parameter. These "curves of zero velocity" may be looked upon as barriers in the sense that an orbit for which the constant of the Jacobian integral equals C' can never cross any of these curves of zero velocity for which C' exceeds C. The curves of zero velocity were first introduced by Hill with application to the moon's motion and have figured prominently in more recent studies of the restricted problem.

A totally different approach to the solution of the problem of three bodies was made by using developments in powers of a variable related to the time. If applied to the original equations the method fails owing to the singularities of the differential equations that correspond to collisions. These singularities may be removed by suitable changes of variables, a procedure known as regularization. The first significant step in this direction was made by P. Painlevé. In 1912 K. F. Sundmann obtained a solution for the general problem of three bodies that can be expanded as power series which are convergent, but not uniformly so, for all values of the time. This result is of great theoretical interest, although its actual application to astronomical problems is excluded by practical difficulties. Moreover, the form of the solution does not reveal the character of the orbits.

In the restricted problem, the use of the Jacobian integral permits the elimination of one of the velocity components. Hence the motion can be represented completely by a trajectory in a three-dimensional phase space comparable with a streamline in a noncompressible fluid. This approach permits an attack upon problems that were not accessible by other methods. The earlier developments are due to Poincaré; important advances were made by G. D. Birkhoff, especially on questions concerning the probability that a trajectory returns to the same small region in space.

BIBLIOGRAPHY.—An elementary exposition of the principles of celestial mechanics is found in Russell, Dugan and Stewart, *Astronomy*, vol. i, chap. x (1926). Introductory treatises are: F. R. Moulton, *Introduction to Celestial Mechanics*, 2nd. ed. (1914); H. C. Plummer, *An Introductory Treatise on Dynamical Astronomy* (1918). The standard treatise covering developments through the 19th century is F. Tisserand, *Traité de Mécanique Céleste*, 4 vols. (1889–96). Excellent chapters on the mathematical aspects of the problem of three bodies are contained in E. T. Whittaker, *A Treatise on the Analytical Dynamics of Particles and Rigid Bodies*, 4th. ed. (1937). Other important works for specialists are: J. H. Poincaré, *Les Méthodes Nouvelles de la Mécanique Céleste*, 3 vols. (1892–99); E. W. Brown, *An Introductory Treatise on the Lunar Theory* (1896); J. H. Poincaré, *Leçons de Mécanique Céleste*, 3 vols. (1905–10); *Enc. der Math. Wiss.*, vol. vi, 2A, 2B, (1905–34); G. W. Hill, *Collected Math. Works*, 4 vols. (1905–07); G. D. Birkhoff, *Dynamical Systems* (Amer. Math. Soc. Colloquium Publ., vol. ix, 1927); A. Wintner, *The Analytical Foundations of Celestial Mechanics* (1941). (D. BR.)

CELESTIAL SPHERE, the imaginary sphere of indefinite radius on which the positions of the fixed stars are defined by their directions relative to an observer at its centre. The earth's axis meets the celestial sphere in two points, the *celestial poles.* (*See* ASTRONOMY: *Observational Astronomy.*)

CELESTINA, LA, the popular alternative title attached from 1519 (or earlier) to the anonymous *Comedia de Calisto y Melibea,* a Spanish novel in dialogue which was celebrated throughout Europe during the 16th century. The authorship of the *Celestina* and the date of its composition are doubtful. An anonymous prefatory letter in the editions subsequent to 1501 attributes the book to Juan de Mena or Rodrigo Cota, but this ascription is universally rejected. The prevailing opinion is that the author of the 21 acts was Fernando de Rojas, apparently a Spanish Jew resident at the Puebla de Montalban in the province of Toledo; R. Foulché-Delbosc, however, maintains that the original 16 acts are by an unknown writer who had no part in the five supplementary acts. Some scholars give 1483 as the date of composition; others hold that the book was written in 1497. These questions are still unsettled. The *Celestina* excels all earlier Spanish works in tragic force, in impressive conception, and in the realistic rendering of characters drawn from all classes of society. It passed through innumerable editions in Spain, and was the first Spanish book to find acceptance throughout western Europe. A Latin version by Caspar Barth was issued under the title of *Pornoboscodidascalus latinus* (1624) with all the critical apparatus of a recognized classic. James Mabbe's English rendering (1631) is one of the best translations ever published. The original edition of 1499 has been reprinted by R. Foulché-Delbosc in the *Bibliotheca Hispanica,* vol. xii (1902).

Foulché-Delbosc, "Observations sur la Célestine" in the *Revue hispanique,* vol. vii, pp. 28–80 (1900) and vol. ix, pp. 171–199 (1902); and K. Haebler, "Bemerkungen zur Celestina," in the *Revue hispanique,* vol. ix, pp. 139–170 (1902).

CELESTINE (CAELESTINUS), the name of five popes:

CELESTINE I (Saint), pope from 422 to 432. After his triumph over the dissensions caused by the faction of Eulalius (*see* BONIFACE I) his episcopate was peaceful. He instructed Cyril, bishop of Alexandria, to inquire into the doctrines of Nestorius. To ex-

tirpate Pelagianism, he sent to Britain a deacon, Palladius, at whose instigation St. Germanus of Auxerre followed to inculcate orthodoxy among the clergy of Britain. Celestine also commissioned Palladius to preach the gospel in Ireland which was beginning to rally to Christianity. Celestine was the first pope who is known to have taken a direct interest in Britain and Ireland.

(X.)

CELESTINE II (Guido di Castello), pope from 1143 to 1144, came of obscure Umbrian parentage. He was able and learned, and studied under Peter Abélard, whom he held in lasting admiration. Made cardinal deacon in 1127, he was pope from Sept. 26, 1143, to March 8, 1144.

He removed the interdict which Innocent II had employed against Louis VII of France.

CELESTINE III (Giacinto Bobone), pope from 1191 to 1198, once cardinal deacon of Santa Maria in Cosmedin, became pope on March 30, 1191. Henry VI of Germany forced the pontiff to crown him emperor and three years later took possession of the Norman kingdom of Sicily; he refused tribute and the oath of allegiance, and even appointed bishops subject to his own jurisdiction; moreover, he gave his brother in fief the estates which had belonged to the countess Matilda of Tuscany. Celestine dared not excommunicate him.

He played throughout a temporizing policy, refusing even to take decisive action when the emperor imprisoned Richard Coeur de Lion as he was returning from the crusade. Richard had been set free before the dilatory pope put Leopold of Austria, his original captor, under the ban.

Celestine died on Jan. 8, 1198.

CELESTINE IV (Godfrey Castiglione), pope in 1241, nephew of Urban III (1185–87), was archpriest and chancellor at Milan, before he joined the Cistercians. In 1227 Gregory IX created him cardinal priest, and in 1239 cardinal bishop of Sabina. Elected to succeed Gregory on Oct. 25, 1241, he died on Nov. 10 before consecration.

CELESTINE V (St. Peter Celestine or Peter of Morrone), pope in 1294, was born of poor parents at Isernia about 1215, and adopted an eremitical way of life on Monte Morrone. He attracted other ascetics whom he organized into a congregation which was later called the Celestines (*q.v.*). They were incorporated by Urban IV into the Benedictine order (1263). His *Opuscula* (Naples, 1640) are probably not genuine.

A fight between the Colonna and the Orsini, as well as dissensions among the cardinals, prevented a papal election for more than two years after the death of Nicholas IV. Finally, Celestine was elected on July 5, 1294.

Apocalyptic notions then current doubtless aided his election, for Joachim of Floris and his school looked to monasticism to deliver the church and the world. Multitudes came to Celestine's coronation and he began his reign the idol of visionaries, of extremists and of the populace. But the pope was in the power of Charles II of Naples; and became his tool against Aragon. When he wished to abdicate, Benedetto Gaetano, destined to succeed him as Boniface VIII, removed all scruples against this unheard of procedure by finding a precedent in the case of Clement I. Celestine abdicated on Dec. 13, 1294, and died in a monastic cell in the castle of Fumone on May 19, 1296. He was canonized as St. Peter Celestine by Clement V in 1313.

CELESTINE or CELESTITE, a name applied to native strontium sulphate ($SrSO_4$), having been suggested by the celestial blue colour which it occasionally presents. It is usually colourless, or a delicate shade of blue. It crystallizes in the orthorhombic system, being isomorphous with barytes (*see* BARITE). The cleavage is a perfect parallel to the basal pinacoid, and a less marked parallel to the prism. Although celestine much resembles barytes in its physical properties, having for example the same hardness (3), it is less dense, its specific gravity being 3.9. It is less abundant than barytes, but is, however, much more soluble.

Celestine occurs in the Triassic rocks of Britain, especially in veins and geodes in the Keuper marl in the neighbourhood of Bristol. At Wickwar and Yate in Gloucestershire it is worked for industrial purposes. Colourless crystals of great beauty occur in association with calcite and native sulphur in the sulphur deposits of Sicily, as at Girgenti. Very large tabular crystals are found in limestone on Strontian island in Lake Erie; and a blue fibrous variety from near Frankstown, Blair county, Pa., is notable as having been the original celestine on which the species was founded by A. G. Werner in 1798.

Celestine is much used for the preparation of strontium hydrate, which is employed in refining beetroot sugar. (F. W. R.)

CELESTINES, a religious order founded about 1260 by Peter of Morrone, afterwards Pope Celestine V. (1294). It was an attempt to unite the eremitical and cenobitical modes of life. Peter's first disciples lived as hermits on Mount Majella in the Abruzzi. The Benedictine rule was taken as the basis of the life, but was supplemented by regulations notably increasing the austerities practised. The form of government was borrowed largely from those prevailing in the mendicant orders. Indeed, though the Celestines are reckoned as a branch of the Benedictines, there is little in common between them. During the founder's lifetime the order spread rapidly, and eventually there were about 150 monasteries in Italy, and others in France, Bohemia and the Netherlands. The French houses formed a separate congregation, the head-house being in Paris. The French Revolution and those of the 19th century destroyed their houses, and the Celestine order seems no longer to exist.

CELIBACY, the state of being unmarried. In the original Latin (*caelibatus*, from *caelebs*, unmarried) it meant merely the fact of being unmarried, but was later restricted almost entirely to the perpetual renunciation of marriage, especially for religious motives. Celibacy was a practice of various religions even in pre-Christian times, as exemplified in the Roman vestal virgins and in Buddhist monasticism. Judaism frowned on celibacy, and considered childlessness a reproach, for it banished the hope of begetting the Messiah. But marriage was rejected by the majority of the Jewish sect of Essenes, which arose about two centuries before Christ, probably from Persian-Babylonian influences during the captivity and from contact with Hellenism through the Greek language.

Christ commended celibacy for the sake of the kingdom of heaven (Matt. xix, 12), but did not prescribe it; and St. Paul praised virginity as better than marriage (I Cor. vii; 7, 32–40). Celibacy was a common practice among the early Christians, who were inspired by the example of Christ, the virtues of self-control and self-denial, and the freedom from family cares which would leave greater liberty for prayer, contemplation and apostolic activity, and would win the confidence and respect of the people. The practice was not confined to the clergy, but it became by church law an obligation for those who wished to embrace the clerical state.

Origins of Clerical Celibacy.—The majority of scholars agree that the law of clerical celibacy was not of apostolic origin. St. Paul recommended celibacy, but he also wrote that a bishop should be a man of one wife (1 Tim. iii, 2; Titus i, 6). This was generally understood to exclude from bishoprics, not unmarried men, but rather men who had married more than once, at least after their baptism. A few contemporaries of St. John Chrysostom found in these texts a command that a bishop should have a wife, and this interpretation was revived in the 16th century by the Protestant reformers.

While no strict law of celibacy existed during the first three centuries of Christianity, its practice was in honour among the clergy from the time of the apostles. Tertullian admired the number of celibate clergy and Origen contrasted the spiritual fatherhood of the priests of the New Testament with the carnal paternity of the Levites of the Old Law. At the same time, ac-

cording to Clement of Alexandria, the church approved of clergymen who had married; if they used their marriage rights without sin, they would be saved by having children. When a law of celibacy was proposed in the ecumenical council of Nicaea in 325, Paphnutius, a celibate Egyptian bishop, objected that nothing should be added to the ancient tradition which opposed marriage after ordination, but did not prohibit wedded life for those who married before ordination. The council accepted this advice and contented itself with the provision that the clergy should not have in their houses unmarried women other than near relatives.[1]

Celibacy in the Oriental Church.—The law of clerical celibacy developed during and after the 4th century, more stringently in the west than in the east. The practice of celibacy was esteemed in the eastern church, but was not universal. The council of Ancyra in 314 allowed a candidate for the diaconate to state his choice of celibacy or marriage, and bound him accordingly. A few years later the council of Gangra condemned any disdain for the ministry of married priests. The bishops, however, practised continence even when married, and this custom gradually passed into church law, for which Justinian established civil sanctions. The discipline of the oriental church was finally fixed in the council of Trullo in 692. Absolute continence was prescribed for bishops; if they had been married they could not be consecrated unless their wives would enter monasteries. Ordained priests, deacons, and subdeacons could not marry, but they were free to retain wives they had taken before ordination.[2] This law has remained substantially the same in the eastern churches, but the practice has been to select bishops only from the unmarried priests.

Many of the eastern churches that have reunited with the Roman see have also accepted the stricter Roman discipline, but the retention of the old oriental practice has been tolerated in some of them.

The Early Latin Church.—After the beginning of the 4th century the custom of clerical celibacy gradually evolved into a legal obligation in the western church. The council of Elvira (Grenada) about the year 300 prescribed continence for bishops, priests and deacons.[3] This was merely a provincial council local to a part of Spain, but it has been prominent in the history of celibacy since it established the earliest recorded legislation on this subject. The same discipline was decreed in 386 by the church in Rome, and Pope Siricius set about making it universal in the Latin church. By letters to Spain and Africa he notified the bishops of the ruling, and prescribed penalties for violations.[4] A few years later Pope Innocent I wrote to the bishops of Rouen (404) and Toulouse (405) in the same vein. Councils in Carthage in 390 and 401 prohibited matrimonial intercourse of priests and deacons. At about the same time councils in Toledo and Turin barred advancement in orders if deacons or priests failed to observe continence with their wives. French councils demanded a promise of perpetual chastity from candidates for the diaconate. The church in England and Ireland also followed the continental law. Pope St. Leo I (440–461) restated the law of celibacy and included subdeacons among its subjects.[5]

The law met with opposition and St. Jerome knew of more than 300 married bishops. Other writers and many epitaphs of the clergy recorded clerical marriages as late as the 6th century. Time was required for the law to be universally accepted, but it was clear and definite after the 6th century except for subdeacons, for whom it became general in the 9th century.

Since married men received orders and undertook the obligation of celibacy, their wives were to be treated as sisters thereafter, and were called deaconess, priestess and episcopess. The wife of a priest or deacon remained mistress of his house, but a bishop's wife was to live in a separate home, and measures of vigilance were prescribed for them. But the proximity of the married couple was a source of danger, and violations of the law were not rare, although it was generally well observed during the Merovingian period, and many of the clergy were unmarried.

In the 8th century violations of the law became more frequent especially when Charles Martel began to distribute benefices to men who were more interested in the income than in the duties of a cleric. There was chaos in the Frankish church, as St. Boniface reported to Pope Zachary, but the saint succeeded in effecting a great reform there. In Spain King Witiza went so far as to abrogate the law of celibacy. With the advent of the Carlovingians better discipline was restored. Various councils renewed the old canons and Charlemagne sanctioned the traditional church law. But after the break-up of his empire the laws of both church and state were largely disregarded. During the 10th and most of the 11th centuries the laxity of the clergy made clerical marriages quite numerous. In many places the abuse was so rampant that marriage tended to become the normal state of the clergy with no stigma attached to it. The term "concubinage" was applied to these unions, but not in its strict sense, for the church had not yet made holy orders an impediment to valid wedlock. Some clerics did keep mistresses, but others contracted true marriages, either secretly, or even openly, as Pope Leo VII deplored in a letter to the Gauls and Germans.

In the middle of the 10th century the bishop of Augsburg was St. Ulric to whom an extant letter in favour of sacerdotal marriage has been attributed. Dr. Henry C. Lea in his *History of Sacerdotal Celibacy* vouched for its authenticity, but no careful scholar after the middle of the 19th century would disagree with August Potthast's evaluation in his bibliography of mediaeval history. He catalogues the letter under the heading, "Pseudo-Udalricus" as a fabrication of about 1075, a century after Ulric's death in 973, and a period of sharp controversy between the papacy and the empire.[6]

Reforms of Gregory VII.—In the 11th century the church began to re-establish the old canons, but the long-standing abuse was not repressed without a struggle. It took the exhortation of the most virtuous among the clergy and the drastic legislation of the greatest of the popes to bring about a reform. Severe laws and penalties were enforced, not only against the incontinent clergy, but also against their illegal partners. Some of the clergy who were liberated serfs took free women to wife in order to have children who would be free and inherit their property according to the civil law. Hence Benedict VIII, in the synod of Pavia about 1022, decreed the children of the clergy to be serfs of the church, and Henry II incorporated this into the law of the empire.

Leo IX in the Lateran synod of 1049 enslaved the concubines of the Roman clergy to the Lateran palace. Various synods in England and France allowed the rural clergy to keep the wives they had taken, but forbade future clerical marriage.

St. Peter Damien and Hildebrand were strong supporters and advisers of the popes of this period, and when Hildebrand became Pope Gregory VII in 1073, he made strenuous efforts to restore the ancient discipline. Many clerics believed that contrary custom had abrogated the law and made their marriages blameless, so when Gregory's legates instructed the German hierarchy to enforce celibacy, some of the clergy threatened to give up their ministry rather than their wives, saying that the pope might get angels to take their places. Similar disturbances occurred in France, but Gregory was not to be turned from his purpose. He took the unprecedented and dangerous step of subjecting the clergy to the judgment of the laity. He wrote several letters exhorting princes and people to refuse, and even to hinder by force, the ministrations of priests who were tainted with incontinence.[7] The temporary harm of such a measure was justified by the permanent gain effected, for the efforts of Gregory and his immediate successors brought about the desired reform. One of the principal causes of clerical incontinence was removed by the eventual settlement of the conflict over lay investitures. Finally the first and second ecumenical councils of the Lateran

(1123 and 1139) removed the possibility of clerical marriage after ordination to the subdiaconate by making this and higher orders an impediment to valid marriage.[1] After these decrees the unlawful unions of clerics were mere concubinage. These steps led to a general observance of the law so that in the 13th century concubinage was the rare exception among the clergy.

A new decline set in during the 14th and 15th centuries and various princes and churchmen proposed the adoption of the practice of the oriental church. The question was raised, without result, in the councils of Vienne (1311–12), Constance (1414–18) and Basel (1431–49). Some priests claimed special dispensations from the law of celibacy and even used forged papal documents to prove their claim.

In the 16th century Martin Luther and other Protestant leaders attacked clerical celibacy, and as Protestantism progressed, some Roman Catholics thought a relaxation of the law might help to restore unity in the church.

Modern Roman Discipline.—The great reforming council of Trent, after long discussion, retained the earlier laws, including the Lateran decree that holy orders nullify an attempt to marry, and defined as an article of faith the church's power so to legislate.[2] The observance of the law was greatly forwarded by founding seminaries in which the candidates were trained in virtue while being instructed in preparation for ordination.

After Trent, at the request of Ferdinand I and Maximillian II, Pope Pius IV for a time considered permitting clerical marriage in Germany, but the question was shelved and the law of Trent remained the settled legislation of the church. It was incorporated into the 1918 *Codex Juris Canonici* in canons 132, 987 and 1072.

Dispensations have sometimes been granted to subdeacons and deacons who returned to lay status, but to priests very rarely and only in view of the common welfare. General dispensations were given in England to the clergy who had embraced Anglicanism and married, but who wished to return to Rome under Mary Tudor; and to the small section of the French clergy who had unfrocked themselves and married in fear of the Terror.

The church never absolutely prohibited the ordination of married men, but to protect the rights of their wives the practice arose of refusing ordination unless the wife freely vowed perpetual chastity. This was the law in the 14th century.[3] The 1918 code of canon law prohibited ordination of a married man without the very rarely granted dispensation of the Holy See.

There has been occasional laxity since the council of Trent, and in the early 19th century there was German agitation for a mitigation of the law, but in general the celibacy of the Roman Catholic clergy has won respect and influence in and outside their church.

The practice of celibacy was revived in the Church of England during the latter part of the 19th century by some monastic institutions which also made foundations in America.

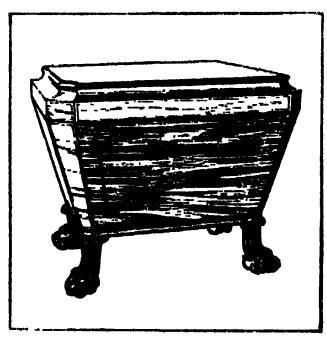
BIBLIOGRAPHY.—Among the best treatments of celibacy are F. X. Funk, "Cölibat und Priesterehe," in his *Kirchengeschichtliche Abhandlungen und Untersuchungen*, 1897, vol. I, pp. 69-120; and E. Vacandard, "Célibat," in *Dictionnaire de Théologie Catholique*, 1923, vol. II, part 2, col. 2068–2088. A good historical and archaeological treatment of the first eight centuries is found in H. Leclercq, "Célibat," in *Dictionnaire d'Archéologie Chrétienne et de Liturgie*, 1925, vol. II, part 2, col. 2802–2831, where a complete bibliography also is found. A good English treatment with detailed discussion of celibacy in England is Herbert Thurston's "Celibacy of the Clergy," in *The Catholic Encyclopedia*, vol. III, pp. 481–488. The best known opponent of clerical celibacy is Henry C. Lea, *History of Sacerdotal Celibacy in the Christian Church*, 1907, but he has been charged with superficial and biased scholarship by Roman Catholic scholars and some others. Disaffection was expressed by Johann and Augustin Theiner in *Einführung der erzwungenen Ehelosigkeit*, 1828, which was prohibited by the Holy See and afterward repudiated by Augustin Theiner.

(H. R. W.)

CELINA, an incorporated village in western Ohio, U.S.A., on Grand lake (or Lake St. Marys); the county seat of Mercer county. It is served by the Cincinnati Northern and the Nickel Plate railways. Pop. (1950) 5,703 by the federal census. Celina is a summer resort, the commercial centre of a farming region and an important furniture-manufacturing town. Stearic acid, printed and metal products are also manufactured. The village was settled in 1834 and incorporated in 1885. Grand lake is an artificial lake, 9 mi. long by 3 mi. wide, built to feed the old Miami and Erie canal.

CELL, originally a small detached room in a building (Lat. *cella,* a small room), particularly a small monastic house (*see* ABBEY).

Also used for the small sleeping apartments of the monks, or the small dwelling of a hermit. This use still survives in the small separate chambers in a prison (*q.v.*). The word also denotes various small compartments which build up a compound structure, such as honeycomb, etc.



In electricity a cell may be defined as a system which produces electromotive force by chemical action.

For voltaic, dry and concentration cells *see* BATTERY; for gas cell *see* HYDROGEN IONS; for standard cell *see* INSTRUMENTS, ELECTRICAL.

In biology the term cell denotes microscopic structural elements which form the bulk of the tissues of animals and plants of visible dimensions. The precise meaning of the term cell in biological literature is set forth in the article CYTOLOGY (*q.v.*). When the term came into usage in biology, it referred to the smallest units of structure that the microscope could reveal in the animal or plant body. First used by Robert Hooke (1665) for the minute cavities of cork, a tissue which he described as made up of "little boxes or cells," it is a survival from the microscopic descriptions of plant structure made by 17th century botanists, and as such is really a misnomer, for tissues of animals rarely display the honeycomb-like appearance of pith, cork, etc., when examined microscopically. To-day the cell is recognized to be a complex, consisting of a number of well-defined structures (*nucleus, mitochondria,* etc.) so that it is no longer possible to define the cell as the ultimate structural unit of living matter. On the other hand, it is a physiological unit. It is the delimitation of this characteristic complex of microscopically visible units by a boundary which possesses the physical property of differential permeability to different kinds of molecules that characterizes the individual cell, which has thus come to be regarded as a unit of physiological activity of a certain order. The fact that the respective contributions of the maternal and paternal parents to the physical constitution of the offspring are derived in each case from a single cell of the parent-body has revolutionized the study of heredity; and has stimulated a considerable body of research which makes it possible to-day to envisage the structural basis of hereditary transmission and the determination of sex.

Thus the Cell Doctrine, *i.e.,* the recognition of the cell originally as the structural unit of the body and later as a unit of physiological activity, has exerted its influence on every department of biological thought since the doctrine was formulated by M. J. Schleiden and Theodor Schwann in 1839.

[3] See *Corpus iuris canonici, cap. unic., tit. 6, de voto et voti redemptione, in Extravag. Ioannis XXII.*

came, the cellaret was a detached receptacle. It was most commonly of mahogany or rosewood, many-sided or even octagonal, and occasionally oval, bound with broad bands of brass and lined with zinc partitions to hold the ice for cooling wine. Sometimes a tap was fixed in the lower part for drawing off the water from the melted ice. Cellarets were usually placed under the sideboard, and were, as a rule, handsome and well-proportioned; but as the artistic impulse which created the great 18th-century English school of furniture died away, their form grew debased, and under the influence of the British Empire fashion, which drew its inspiration from a bastard classicism, they assumed the shape of sarcophagi incongruously mounted with lions' heads and claw feet. Hepplewhite called them *gardes du vin;* they are now nearly always known as "wine-coolers."

CELLE, a town of Germany, in the district of Hanover, Lower Saxony, on the left bank of the navigable Aller, near its junction with the Fuse and the Lachte, 23 mi. N.E. of Hanover. Pop. (1950) 59,667. Founded in 1292, the town was the residence of the dukes of Lüneburg-Celle, a cadet branch of the ducal house of Brunswick, from the 14th century until 1705. The most interesting building is the former ducal palace, begun in 1485 in Late Gothic style, but with extensive Renaissance additions of the late 17th century. There are manufactures of biscuits, umbrellas, leather, sugar, dyes and paper, and trade is carried on in wax and timber. Celle is the seat of the court of appeal from the superior courts of Aurich, Detmold, Göttingen, Hanover, Hildesheim, Lüneburg, Osnabrück, Stade and Verden.

CELLIER, ALFRED (1844–1891), English composer of light operas of which one, "Dorothy," enjoyed prodigious popularity, running from Sept. 25, 1886, till April 1889. "The Mountebanks," to a libretto by W. S. Gilbert, was also very successful.

CELLINI, BENVENUTO (1500–1571), Italian artist, metal worker and sculptor, born in Florence on Nov. 1, 1500. His father was a musician and artificer of musical instruments, who married Maria Lisabetta Granacci, and 18 years elapsed before they had any children. Benvenuto (meaning "welcome") was the third child. The father destined him for his own profession and tried to thwart his inclination for design and metal work. At 15, however, he was apprenticed to a goldsmith, Antonio di Sandro, named Marcone. He had already attracted some notice in Florence when, being implicated in a brawl, he was banished to Siena where he worked for Francesco Castoro, a goldsmith. He visited Bologna and Pisa, and returned to Florence before he went to Rome in 1519. To this period belong a silver casket, some silver candlesticks, a vase for the bishop of Salamanca, and the gold medallion of "Leda and the Swan"—the head and torso of Leda cut in hard stone—executed for Gonfaloniere Gabbrello Cesarino, which is now in the Vienna museum. In the attack upon Rome (1527) by the constable de Bourbon, the bravery of Cellini proved of signal service to Pope Clement VII.; if we may believe his own accounts, his was the hand which shot the Bourbon dead, and he afterwards killed Philibert, prince of Orange. His exploits paved the way for a reconciliation with the Florentine magistrates and his return to Florence. Here he worked on medals, the most famous of which are "Hercules and the Nemean Lion," in gold repoussé work, and "Atlas supporting the Sphere," in chased gold. From Florence he went to the court of the duke of Mantua, and thence again to Rome, where he was employed in the working of jewellery and the execution of dies for private medals and for the papal mint. Here, in 1529, he avenged a brother's death by slaying the slayer; soon afterwards he had to flee to Naples to shelter himself from the consequences of an affray with a notary, Ser Benedetto, whom he wounded, but on the accession of Paul III. he was reinstated. The plots of Pierluigi Farnese, a natural son of Paul III., led to his retreat from Rome to Florence and Venice, and once more he was restored with greater honour than before.

On returning from a visit to the court of Francis I., being now aged 37, he was imprisoned for some time on a charge (apparently false) of having embezzled during the war the gems of the pontifical tiara. At last, however, he was released at the intercession of Pierluigi's wife, and more especially of the Cardinal d'Este of Ferrara. For a while after this he worked at the court of Francis I. at Fontainebleau and in Paris. But the enmity of the duchesse d'Etampes and the intrigues of the king's favourites led him, after about five years of laborious and sumptuous work, to retire in 1545 in disgust to Florence. During the war with Siena, Cellini was appointed to strengthen the defences of his native city. In 1565 he married Piera de Salvadore Parigi. He died in Florence on Feb. 13, 1571, and was buried in the church of the Annunziata.

Besides the works in gold and silver which have been mentioned, Cellini executed several pieces of sculpture. The most distinguished is the bronze group of "Perseus holding the head of Medusa," now in the Loggia dei Lanzi at Florence, one of the most typical monuments of the Italian Renaissance.

Not less characteristic of its splendidly gifted and barbarically untameable author are his autobiographical memoirs begun in Florence in 1558—a production of the utmost energy, directness, and racy animation, setting forth one of the most singular careers in all the annals of fine art. His amours and hatreds, his passions and delights, his love of the sumptuous and the exquisite in art, his self-applause and self-assertion, make this one of the most singular and fascinating books in existence. The original manuscript is at the Laurenziana in Florence. Cellini also wrote treatises on the goldsmith's art, on sculpture, and on design (translated by C. R. Ashbee, 1899).

Among his works of art, many of which have perished, were a colossal Mars for a fountain at Fontainebleau and the bronzes of the doorway, coins for the papal and Florentine states, a Jupiter in silver of life size, and a bronze bust of Bindo Altoviti. His other works in existence to-day are the celebrated salt-cellar made for Francis I. at Vienna; a medallion of Clement VII. in commemoration of the peace between the Christian princes, 1530, signed with the artist's name; a medal of Francis I. with his portrait, also signed; and a medal of Cardinal Pietro Bembo. Cellini, while employed at the papal mint at Rome during the papacy of Clement VII. and later of Paul III., executed the dies of several coins and medals, some of which still survive. He also executed in 1535 for Alessandro de' Medici, first duke of Florence, a 40-soldi piece, with a bust of the duke on one side and standing figures of the saints Cosmo and Damian on the other.

The important works which have perished include the uncompleted chalice intended for Clement VII.; a gold cover for a prayer-book as a gift from Pope Paul III. to Charles V.; large silver statues of Jupiter, Vulcan, and Mars, wrought for Francis I. during his sojourn in Paris; a bust of Julius Caesar; and a silver cup for the cardinal of Ferrara. The magnificent gold "button," or morse, made by Cellini for the cope of Clement VII., appears to have been sacrificed by Pius VI., in furnishing the indemnity of 30,000,000 francs demanded by Napoleon in 1797. Fortunately there are in the print room of the British Museum three water-colour drawings of this splendid morse done by F. Bertoli in the first half of the 18th century.

CELLOPHANE, a thin film of regenerated cellulose, usually clear and transparent, used primarily as a flexible packaging material. While the word "cellophane" is a trade mark in England, France, Canada and many other countries, in the United States it became, by court decision, a generic term.

In 1892 the English chemists C. F. Cross, E. J. Bevan and C. Beadle discovered viscose, a solution of cellulose treated with caustic soda and carbon disulphide. Six years later C. H. Stearn was granted a British patent for producing films from viscose. It

was not until 1911, however, that J. E. Brandenberger, a Swiss, designed a machine for continuous production of a strong, transparent film. Brandenberger coined the term "cellophane" by combining "cellulose" and "diaphane," the French word for "transparent."

World War I delayed large-scale development. In 1920 a French company, La Cellophane, was formed, and a cellophane plant was built at Bezons, near Paris. Three years later E. I. du Pont de Nemours & Company acquired rights from La Cellophane to manufacture the product in the United States and produced the first U.S.-made cellophane at Buffalo, N.Y., in 1924.

By the 1950s, U.S. production, which was less than 500,000 lb. in 1924, was estimated at more than 250,000,000 lb. annually and was believed to account for well over half the world's supply, although no precise production figures were published.

Several factors contributed importantly to cellophane's growth. Moistureproof cellophane, invented in 1927 by W. H. Charch and K. E. Prindle, gave the film new usefulness as a protective wrap for foods. By the 1950s about 90% of the U.S. production was moistureproof, and about 70% of the total went to the food industry. More than 50 varieties of cellophane had been developed. Basically, the film is transparent, odour resistant, tough, grease-proof and gas impermeable. It can be made in various thicknesses and colours. By applying special coatings, it can be made moistureproof, partially moistureproof, and heat-sealing.

Cellophane manufacture starts with steeping of sheets of wood pulp in caustic soda to form alkali cellulose. After removal of excess liquids, the sheets are shredded, aged to control molecular weight, and discharged into steel drums known as barattes. Carbon disulphide is added to the slowly rotating barattes, forming sodium cellulose xanthate. The xanthate is dissolved in another caustic solution to form viscose.

Carefully ripened viscose is piped to the casting machine, where it is extruded through a metal slit into an acid bath in which it coagulates to a film and is regenerated into cellulose. Driven rolls carry the film through a further series of baths where it is washed and bleached, and softening materials are added. The film then enters the dryer, passing over heated rolls and through circulating hot air. Finally, it is wound up in mill rolls, which may weigh as much as 950 lb. and contain up to 5 mi. of film.

If the cellophane is to be coated, the film is led through a coating bath, over doctor knives or rolls to remove excess coating and to distribute the coating evenly, and then through drying and humidifying chambers.

Finished mill rolls are commonly slit to widths required for use on automatic packaging machinery, though some are unwound on large drums to be cut and trimmed to sheet form for use in hand-wrapping operations.

CELLULOID, the first synthetic plastic material, also known as xylonite or artificial ivory. The invention of celluloid in 1870 in the U.S. is commonly ascribed to J. W. Hyatt and I. S. Hyatt, who first realized the necessity of working cellulose nitrate, camphor and alcohol under heat and pressure. Their efforts were based upon earlier investigations by A. Parkes and D. Spill in Great Britain. In the U.S., "Celluloid" is a trade name. Celluloid is a homogeneous colloidal dispersion of cellulose nitrate and camphor. Its commercial importance persists because of its good properties: resilience; high tensile strength (up to 12,000 lb. per square inch); toughness; a density of 1.40; high lustre; low cost; uniformity; resistance to water, oils and dilute acids; ready workability; and the great variety of colours, from transparent crystal and pastel shades through bizarre mottles and pearls, in which it can be fabricated.

Since it is based upon a nitrate ester of cellulose, a long-chain polymer, Celluloid is thermoplastic in character. It can be worked in moulds at 200° to 220° F., and it becomes brittle at −70° F. At room temperatures it may be sawed, drilled, turned, planed, buffed and polished. Direct sunlight, or storage above 120° F. will discolour it, and decomposition sets in above 365° F. The flammability is best controlled by the use of it in articles of thick cross section, or as a sheath covering other materials which dissipate heat more rapidly.

Although both Celluloid and smokeless powder are made from cellulose nitrate, the degree of nitration for the plastic is much lower than for the propellant, hence the relative safety of the former. Celluloid of the best quality requires nitrated cellulose from purified, bleached cotton linters. These are nitrated with agitation in chrome steel pots with a large excess of concentrated nitric acid in the presence of sulphuric acid. The nitrated fibres are freed from excess acid in centrifuges, and further purified and washed. The wet fibres are then pressed, and the water is displaced with alcohol.

A homogeneous paste is then made by mixing the fibres with more alcohol and camphor in a chrome-lined vacuum kneader. Excess solvent is evaporated; the paste is passed through heavy hydraulic strainers and then milled on heated rolls to mix in colour and fillers, to remove solvent and to form slabs. The slabs are trimmed, fitted in heavy steel baking chases provided with heating channels and pressed; the colloid is thereby compacted into cakes while heated at 190° to 220° F. The mass is cooled, sliced into sheets, seasoned to remove residual solvent and polished. Slabs from the rolls may be extruded into rods or tubes of varied cross section, through a die fed by a screw or hydraulic press.

The great diversity in designs made from Celluloid is accomplished by assembling varicoloured blocks in layers and columns in the baking chase, by incorporating orienting pigments and pearl essences in the roll mass and by mechanically twisting and working the stock before extrusion.

Grades, Fabrication and Uses of Celluloid.—Two main grades of Celluloid were available at mid-20th century. The softer, with 30% to 32% camphor, is extruded to make hammer heads for beating aluminum sheet for aircraft, and oil-resistant handles for screw drivers and chisels. The harder common variety, containing 23% camphor, is used in sheet, rods and tubes. Sheeting, available in thicknesses ranging from 0.005 to 0.250 in., may be cut into blanks, heated and moulded under pressures up to 2,000 lb. per square inch. Thin sheets when warm may be drawn, swaged or blown into doll heads, floating toys and ping-pong balls. Sheeting or thin tubing provides a scuff- and mar-resistant sheathing for wooden shoe heels, toilet seats and bus and trolley stanchions.

The plastic, softened in hot water, is stretched over the form and cooled in place. Piano keys, dresser sets, cutlery handles, dental plates, spectacle frames, accumulator boxes, ammunition components, toothbrushes, drawing curves and cut combs are also made from sheet. Button forms, ornaments, dice, etc., may be cut or formed from rods. Celluloid tubing forms the basis of most fountain pens because of dimensional stability, and resistance to ink and handling. Much tubing is used in Great Britain for the bodies and handles of bicycle pumps.

Although much research had been directed toward a better plasticizer than camphor for Celluloid, nothing really superior had been found by the 1950s. Ortho-nitrodiphenyl, the closest approach, has more colour and odour. Camphor and cellulose nitrate form a weak association complex (J. R. Katz, J. C. Derksen *et al.*, *Z. Phys. Chem.* A, 1930) and give a material which has greater tensile strength than the cellulose nitrate itself. Synthetic camphor makes as good a Celluloid as natural camphor. A small amount of aromatic phosphate replaces camphor in a few special applications, but the thousands of patented processes directed to the flameproofing of Celluloid by admixture of bromate, phosphate or chloride compounds and salts produce inferior materials.

Although less flammable synthetic polymers have replaced Celluloid in such markets as safety glass and telephone mouthpieces, it was still widely used at mid-20th century for its excellent physical properties. Manufacture was carried out in Austria, Belgium, France, Germany, Great Britain, Japan, U.S.S.R., Switzerland and the U.S.

CELLULOSE is the chief constituent of the cell walls of higher plants and comprises at least one-third of all the vegetable matter in the world. It is, therefore, the most abundant of all naturally occurring organic compounds. Cellulose has also been found in the lower species of the vegetable kingdom, such as mosses and ferns, algae and fungi and bacteria. Its occurrence in one representative of the animal kingdom—the marine organisms of the class of Tunicata—has also been reported.

In its natural state, cellulose is accompanied by other materials whose nature and amount vary from plant to plant. Technically, the name cellulose is applied to the products obtained by subjecting vegetable matter to certain purification processes which remove most of the noncellulosic materials. Celluloses from different sources differ in their content of noncellulosic compounds, in the molecular weight of the cellulose and in their fibre structure. The alpha-cellulose content of a cellulose pulp, *i.e.*, the portion insoluble in 17.5% sodium hydroxide at 20° C., serves as a rough measure of its purity. No simple, specific test is available for the identification of cellulose. The formation of cellobiose octaacetate on treatment with a mixture of acetic anhydride and sulphuric acid has been used to demonstrate the presence of cellulose. Cellulose yields characteristic X-ray diffraction patterns which will provide adequate identification. Its density as determined on kier-boiled cotton, is 1.58; mercerized and regenerated cellulose rayons have densities ranging from 1.53 to 1.55.

Despite its wide distribution in nature, most of the cellulose used industrially is obtained from wood and cotton. The composition of wood varies widely with the species. Cellulose is the chief constituent and is present in amounts up to about 50% on an oven-dry basis. Wood also contains appreciable quantities of lignin and polysaccharides other than cellulose in addition to minor amounts of resins, gums, proteins and inorganic matter.

Cellulose (wood pulp) is prepared from wood by removal of the noncellulosic constituents. The following pulping processes are the ones most widely used: (1) the sulphite process, which employs a solution of calcium bisulphite and sulphur dioxide; (2) the soda process, in which a sodium hydroxide solution is used; and (3) the sulphate process, in which pulping is effected by a solution of sodium hydroxide and sodium sulphide; a modern modification of this process involves an acid hydrolysis of the wood prior to the conventional treatment. (The sulphate process was so named because sodium sulphate is the raw material used for the production of the sodium sulphide.) Most of the so-called dissolving wood pulps used in the manufacture of cellulose derivatives are prepared by the sulphite process. As ordinarily prepared, these sulphite pulps contain 88% to 90% alpha-cellulose; alkaline purification treatments are used to obtain pulps with higher alpha-cellulose contents. Increasing amounts of dissolving wood pulp are also being made by the modified sulphate process mentioned above.

Cotton is the purest naturally occurring form of cellulose. Raw cotton contains, on an oven-dry basis, less than 10% of noncellulosic impurities which include proteins, fats and waxes, pectic substances, carbohydrates and inorganic compounds. Chemical cotton for the manufacture of cellulose derivatives is prepared from cotton linters, which are the short fibres removed from cotton seeds after the long fibres have been taken off by ginning for use in textiles.

The cotton linters are purified by pressure digestion at 130° to 180° C. with a solution containing 2% to 5% sodium hydroxide and by a subsequent bleaching to remove colour bodies. Chemical cotton contains about 99% alpha-cellulose.

The viscosity of cellulose, or, more precisely, the viscosity of a solution of cellulose at some definite concentration, is an important property by which the product is characterized for industrial use. Aqueous solutions of cuprammonium hydroxide and of cupri-ethylenediamine hydroxide are the commonest cellulose solvents used for the viscosity determination; cellulose concentrations less than 5% are usually employed. The viscosity is determined at a definite temperature by measuring either the efflux time of the solution in a capillary viscometer, or the time required for a glass or metal sphere to fall through a given depth of solution in a tube of prescribed size. The viscosity determinations are empirical, and the conditions of test must, therefore, be defined exactly in reporting viscosity values.

The moisture content of cellulose, which has an important effect on its chemical behaviour and on its mechanical and electrical properties, rises or drops with increase or decrease in the relative humidity of the atmosphere. The moisture content reached on desorption is higher than that reached on adsorption and varies somewhat with the source and purity, and with the treatment. Thus, for a bleached surgical cotton, the moisture content varies from about 4.6% at 30% relative humidity to about 7.9% at 60% relative humidity; the corresponding figures for a bleached sulphite pulp are 5.6% and 9.5%. High-temperature drying reduces the ability of cellulose fibres to absorb moisture whereas mercerization causes a marked increase in moisture sorption.

Chemical Constitution.—Elementary analysis of the purest available form of cellulose, obtained by purification of cotton, shows that it is composed of 44.4% carbon, 6.2% hydrogen and 49.4% oxygen. These figures correspond to the theoretical composition of a hexose anhydride with the formula $C_6H_{10}O_5$. The hexose anhydride is identified as anhydroglucose (specifically anhydroglucopyranose) by the fact that hydrolysis of cellulose gives an almost quantitative yield (more than 95%) of glucose.

Each anhydroglucose unit contains three alcoholic hydroxyl groups, two secondary and one primary, which can be esterified or etherified. Considerable evidence is available to show that the molecular weight of cellulose is much greater than that of a single anhydroglucose unit. Controlled hydrolysis of cellulose has yielded cellobiose, cellotriaose, cellotetraose and cellopentaose, which contain two, three, four and five anhydroglucose units, respectively. These and other observations prove clearly that cellulose molecules are made up of many anhydroglucose units linked together by primary beta-glucosidic linkages as shown in the formula in Fig. 1.

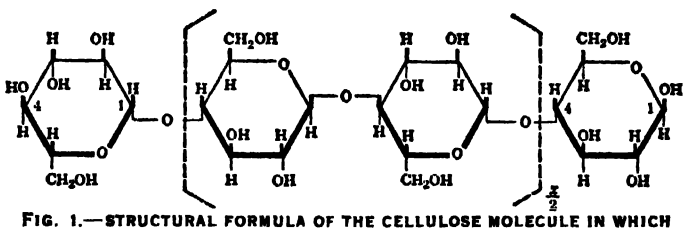

FIG. 1.—STRUCTURAL FORMULA OF THE CELLULOSE MOLECULE IN WHICH $x + 2$ REPRESENTS THE NUMBER OF GLUCOSE ANHYDRIDE UNITS IN THE MOLECULE

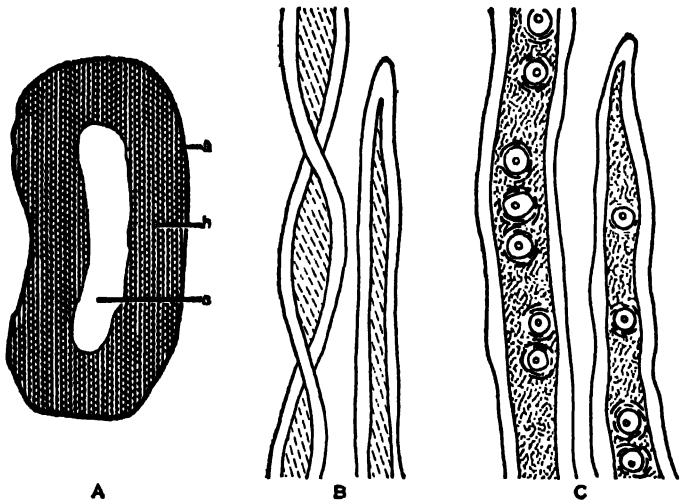

In the Fig. 1 formula, the glucose unit at the extreme right has a potential aldehyde group at position 1, whereas the other terminal glucose unit contains an extra free hydroxyl group at position 4. The potential aldehyde group cannot be detected readily in cellulose of high molecular weight; however, even cellulose whose molecular weight has been reduced somewhat by acid hydrolysis exhibits an aldehydic reducing action. In celluloses which have been treated with oxidizing agents, the aldehyde group has usually been converted to a carboxyl group.

Conclusive evidence has been accumulated to show not only that cellulose has an extremely high molecular weight but also that all the molecules in any sample of the substance are not of the same molecular weight. The evidence for this nonuniformity with respect to molecular weight includes the results of fractional solution and fractional precipitation experiments. Molecular-weight determinations on unfractionated samples of cellulose or its derivatives will, therefore, yield only average values. The usual cryoscopic and ebullioscopic methods are unsuitable for determining large molecular weights. The viscosity method is the simplest and most useful method of molecular-weight determination. It depends on the relation between the molecular weight of a sample of cellulose (or of a cellulose derivative) and the viscosity of a dilute solution of the material. The viscosity method is not an absolute one and must be standardized against the osmotic-pressure, light-scattering or ultracentrifuge method. Some typical

molecular weights based on viscosity measurements are given in the accompanying table:

	Molecular weight (average)	Number of anhydroglucose units per molecule
Native cellulose	More than 570,000	More than 3,500
Chemical cotton	100,000–500,000	600–3,000
Wood pulps	100,000–210,000	600–1,300
Commercial regenerated celluloses	30,000–90,000	200–600
Commercial nitrocelluloses	45,000–875,000	175–3,500
Commercial cellulose acetates	45,000–100,000	175–360

Fibre Structure.—Microscopic examination of the gross structure of native cellulose fibres reveals that, although they have diverse structural patterns, they also have some general structural similarities (Fig. 2). The cotton fibre is composed of a primary wall, which is the thin outer sheath of the fibre and is the portion first formed during growth; a thick secondary wall formed by deposition of cellulose inside the primary wall; and a central canal or lumen. The thin primary wall contains wax and pectic materials in addition to cellulose. The secondary wall has a layered structure resulting from the deposition of daily growth rings, each of which contains one compact and one porous layer. Although woods contain a wide variety of cells, the tracheid fibres (Fig. 2, C) are of chief interest since they constitute most of the fibres in commercial wood pulps. In wood, the fibres are separated from each other by layers of an intercellular substance known as the middle lamella and consisting chiefly of lignin. The fibre proper contains a primary and a secondary wall (both composed largely of cellulose) and a lumen. Investigations with the electron microscope show that the cell walls of all native cellulose fibres are made up of small fibrous elements known as fibrils, whose width may be as small as 0.000001 in.

FIG. 2.—CROSS SECTION (A) OF A COTTON FIBRE SHOWING (a) PRIMARY WALL, (b) SECONDARY WALL AND (c) CENTRAL CANAL. COTTON FIBRES (B) AND WOOD TRACHEIDS (C) SHOW MIDDLE PORTION AND TIP OF FIBRES

X-ray examination of cellulose fibres yields diffraction patterns which show that they are made up, to a large extent, of crystalline cellulose. At least two general types of crystal structure have been observed—native and hydrate. With the exception of the cellulose in the marine alga *Halicystis* which has the hydrate structure, all naturally occurring fibres have the native structure. The hydrate structure occurs in mercerized fibres and in cellulose regenerated from solution or from a derivative.

The X-ray diffraction patterns of native fibres indicate that their crystallinity is discontinuous and that each fibre is an aggregate of small crystalline areas (crystallites or micelles) and amorphous, intercrystalline areas. It is believed that cellulose chains crystallize in such a way that the crystalline regularity is interrupted by irregular regions which behave as amorphous matter toward X-rays and also toward the penetration of swelling and dispersing agents; there is probably a continuous transition between crystalline and amorphous areas of such nature that an individual cellulose chain may pass through several regions of complete order and complete disorder.

Cellulose Degradation.—In the degradation of cellulose, chemical changes occur which result in a reduction of the chain length of the cellulose molecules and, hence, in a weakening of the fibre structure. In some cases, cellulose is deliberately degraded to bring about a desired reduction in the viscosity of the cellulose and of the derivatives made from it. In the hydrolytic degradation which is catalyzed by hydrogen ions (*i.e.*, aqueous solutions of acids), cleavage of 1:4 beta-glucosidic linkages between anhydroglucose units occurs with the formation of two new terminal glucose units. One of these is characterized by the presence of a reducing hemiacetal group, the other by an extra hydroxyl group. If the hydrolysis is carried to completion, the cellulose is converted almost quantitatively to glucose. If only partial hydrolysis takes place, degraded products are obtained to which the name hydrocellulose has been given. A wide variety of hydrocelluloses can be prepared. Their properties are determined by the conditions of the hydrolytic treatment. In general, degradation of cellulose by acids is accompanied by a decrease in viscosity and in tensile strength; by an increase in reducing power and in solubility in aqueous alkalies.

Cellulose can be degraded by oxidizing agents under a wide variety of conditions, and consequently oxycelluloses of widely varying properties can be obtained. Oxidation is of importance in certain commercial operations, such as bleaching, and the reaction of cellulose with oxygen in the presence of alkali in the preparation of viscose and cellulose ethers. In general, oxycelluloses of the reducing type are formed with neutral or acid oxidizing media, whereas alkaline media yield the acidic type of oxycellulose. The exact nature of the chemical changes produced by oxidation is not known, but it appears that three points in the cellulose molecule may be attacked: (1) the aldehydic end groups may be oxidized to carboxyl groups; (2) the primary alcohol groups may be oxidized to aldehyde or carboxyl groups; thus, oxidation with nitrogen dioxide results largely in the conversion of the primary alcohol groups to carboxyls; (3) the 2,3-glycol group in the anhydroglucose unit may be converted to ketone, aldehyde or carboxyl groups. Oxidation with periodic acid causes cleavage at the 2,3-position and formation of aldehyde groups. The action of oxidizing agents other than nitrogen dioxide and periodic acid is much less specific and probably results in attack on different groups in the cellulose molecule. Some types of oxidation do not result in direct scission of the chain molecules but decrease the chemical stability of some of the linkages in the molecule toward alkalies.

Degradation of cellulose takes place on heating, the extent of degradation depending on the temperature and duration of heating. Above 140° C., reducing groups are formed and viscosity decreases slowly. In general, heating lowers the tensile strength of cotton and regenerated cellulose fibres. The degradation by heat is slower in the absence of oxygen. Drastic destruction occurs on heating at relatively high temperatures. Destructive distillation in vacuum yields beta-glucosan, carbon monoxide, carbon dioxide, water and small amounts of gaseous hydrocarbons. Of the derivatives, cellulose acetate seems to possess the best heat stability and nitrocellulose the poorest. Cellulose suffers loss in fibre strength and viscosity on exposure to light. This degradation is accelerated by oxygen, certain metallic catalysts and some dyes; other dyes seem to exert an inhibiting effect. Degradation by light is influenced by temperature and moisture.

A variety of bacteria, fungi and protozoa causes decomposition of cellulose with the ultimate production of carbon dioxide and water. The ability of ruminants, horses and insects to digest cellulose is believed to be caused by the presence in their intestines of cellulose-decomposing bacteria and fungi.

Derivatives.—In the preparation of cellulose derivatives the hydroxyl groups are replaced by substituent groups. The degree of substitution is customarily designated by the average number of hydroxyl units replaced per anhydroglucose unit. Thus, a derivative in which all the hydroxyl groups have been substituted is said to have the maximum substitution of 3.0. If analysis shows that, on the average, 2.5 hydroxyl groups have reacted, the

product has a substitution of 2.5. Each molecule contains hundreds of hydroxyl groups and practically all of these are replaced when fully substituted derivatives are prepared; *e.g.*, cellulose triacetate, trimethyl cellulose. However, most of the derivatives which have attained industrial importance are not fully substituted and contain appreciable amounts of free hydroxyl groups. The chance for reaction of any hydroxyl group is affected by its position in the anhydroglucose unit, by the presence of neighbouring hydroxyl groups and by the position in the fibre structure of the molecule to which it is attached. The rate of reaction of cellulose fibres is determined by the rate of diffusion of reagent to the individual hydroxyl groups. Diffusion is rapid in the amorphous areas of fibres and relatively slow in the crystalline areas. Swelling of the fibres will accelerate diffusion and, hence, the rate of reaction. If swelling takes place uniformly throughout each fibre, the reaction will proceed uniformly. These factors are usually of importance in the preparation of uniform derivatives with substitution less than 3.0.

Uniform substitution in all cellulose molecules is obtained directly when reaction takes place in solution, as in the case of etherification of cellulose dissolved in an aqueous solution of a quaternary ammonium base; any effect caused by fibre structure is eliminated and the distribution of ether groups along the molecule is determined by the relative reactivities of the hydroxyls and by chance. As would be expected in a homogeneous reaction of this type, the primary hydroxyls are more reactive than the secondary hydroxyls.

Nitration of cellulose is unique in that uniform reaction takes place even though fibre structure is retained throughout the reaction. This behaviour is caused by the fact that nitration is an equilibrium reaction which is apparently unaffected by fibre structure, and that the extent of nitration is determined by the composition of the nitrating acid. Cellulose formate is the only other common derivative whose preparation involves an equilibrium reaction; in this case, however, the product dissolves in the esterification reagent. The partially substituted organic acid esters which are of industrial importance (*e.g.*, cellulose acetate) are prepared by first esterifying completely in a medium in which the product dissolves and then uniformly removing some of the substituent groups by hydrolysis while the cellulose ester is in solution. It will be apparent from the foregoing discussion that derivatives with substitution less than 3.0 are not mixtures of cellulose and stoichiometric compounds having substitution of 1, 2 or 3. This view is supported by numerous fractionation experiments on commercial derivatives, in which it was found that the substitution of the individual fractions fell within a comparatively narrow range.

In the preparation of derivatives, substituent groups are introduced into the cellulose molecule; these produce marked changes in physical properties and thereby determine the industrial usefulness of the derivatives. This effect on properties is determined both by the nature of the substituent group and by the degree of substitution. The mechanical and other physical properties of cellulose and cellulose derivatives are affected by their average molecular weight. If their molecular weight is too low, they yield plastics with poor strength or lose their ability to form films or fibres. An increase in molecular weight above the lower limit causes a marked improvement in the strength of plastics, films and fibres. There is also an upper limit beyond which further increase in molecular weight causes only slight improvement in strength. The physical properties are also affected by molecular-weight distribution, that is, by the relative numbers and sizes of the molecules that make up the average value. In particular, the presence of relatively small molecules of cellulose or cellulose derivatives exerts a harmful effect on their strength properties.

In industrial operations, the viscosity of derivatives is used as a measure of molecular weight. The viscosity is controlled by selecting cellulose of a given viscosity for the starting material, by regulating the conditions of the reaction and, in some cases, by appropriate aftertreatment of the cellulose derivative. As in the case of cellulose itself, the viscosity of derivatives is determined on a solution of standard concentration by the capillary viscometer or falling-sphere methods.

Cellulose Esters.—Cellulose nitrate, which is usually referred to as nitrocellulose, is the only ester of cellulose and an inorganic acid which is produced commercially. It is prepared by nitrating cellulose with a mixture of nitric acid, sulphuric acid and water. After removal of most of the acid mixture, the fibrous nitrocellulose is given a series of washing treatments to remove last traces of acid and so obtain a product of good stability. The extent of nitration, which is usually designated by the nitrogen content, and the other properties of nitrocellulose are determined to a large extent by the composition of the nitration reagent and the other reaction conditions. For many purposes, the viscosity of nitrocellulose may be controlled by selecting cellulose of the proper viscosity and by regulating the reaction conditions. In the manufacture of low-viscosity nitrocelluloses for use in lacquers, the product is usually given a special treatment after nitration to reduce the viscosity to the desired level. In the best method for the reduction of viscosity, an aqueous suspension of nitrocellulose is heated under pressure in a continuous digester. Cellulose trinitrate (14.14% N) is not produced commercially because it is difficult to prepare and has limited solubility in common solvents. Nitrocelluloses containing 12.5% to 13.5% nitrogen (substitution 2.4–2.8) are used in explosives; those containing about 12% nitrogen (substitution 2.2) are used in lacquers, photographic film and cement, and celluloid plastics and special lacquers are made with nitrocelluloses containing about 11% nitrogen (substitution 2.0). Cellulose sulphates have been made on a semicommercial scale. Cellulose phosphates have also been prepared but are of only academic interest. The use of sulphuric acid in the reagent mixtures used to nitrate and acetylate cellulose results in the introduction of a small amount of sulphate groups into nitrocellulose and cellulose acetate. Because these sulphate groups exert an adverse effect on the stability of these products, special treatments are used to eliminate sulphate groups and to counteract the effect of any traces that are not removed.

The esters of cellulose with organic acids may be prepared by treating cellulose with the appropriate acid, acid anhydride or acid chloride. Literally hundreds of such esters had been prepared by the 1950s, but only a few of them had attained technical importance. Formic acid is the only organic acid which will effect appreciable esterification of cellulose by direct reaction with it. Cellulose formate has not been used commercially because of its poor resistance to hydrolysis. Cellulose acetate, the most important of the cellulose organic acid esters, is prepared by treating cellulose with more than three moles of acetic anhydride in a suitable solvent such as acetic acid or methylene chloride, in the presence of a catalyst such as sulphuric acid. The product of this reaction is primary cellulose acetate, which approximates cellulose triacetate in substitution (acetyl content, 44.8%). Because of its high melting point, its solubility in only a few solvents and its lack of flexibility, cellulose triacetate has attained only limited use; *e.g.*, in fields where its high moisture resistance is important. By adding to the homogeneous primary acetate reaction mixture an excess of water over that required to decompose unreacted acetic anhydride, the reaction is reversed and acetyl groups are uniformly removed by hydrolysis; the hydrolysis reaction is stopped at the desired point by the addition of a base to neutralize the catalyst. The cellulose acetate is precipitated from solution by the addition of water, and then given a series of washing treatments to remove last traces of acid and thereby ensure good stability. In this way products are obtained with acetyl contents ranging down to about 37% acetyl (substitution about 2.2) and which are soluble in acetone and other solvents. These cellulose acetates find wide use in the manufacture of rayon, plastics and photographic film. Mixed cellulose esters, such as cellulose acetate propionate and cellulose acetate butyrate, attained industrial importance because of their great moisture resistance and wider compatibility with plasticizers than ordinary cellulose acetates. These mixed esters are prepared by esterifying cellulose with mixtures of the appropriate acid anhydrides.

Cellulose xanthate is an important derivative of cellulose which

has only a transitory existence in the process of preparing viscose rayon and cellulose film. In the first step in the process, cellulose is treated with a solution of 18% sodium hydroxide to form so-called alkali or soda cellulose. After removal of the excess sodium hydroxide solution, the alkali cellulose is allowed to stand in contact with air (aging) to reduce viscosity to a desired level. The alkali cellulose is then treated with carbon disulphide to form cellulose xanthate. In commercial practice, slightly more than one xanthate group is introduced for each two anhydroglucose units in the cellulose molecule. The cellulose xanthate is dissolved in 6% sodium hydroxide solution to yield the solution commonly known as viscose, which is then ripened to effect partial decomposition of the cellulose xanthate and to improve its coagulation properties. The ripened viscose is extruded continuously in the form of threads or films into an acid precipitating bath; the regenerated cellulose is then suitably washed and dried.

Cellulose Ethers.—The cellulose ethers which have attained industrial importance include ethyl cellulose, methyl cellulose, carboxymethyl cellulose, hydroxyethyl cellulose and benzyl cellulose. In most cases, these ethers are prepared commercially by the interaction of cellulose and the halide or sulphate of the appropriate alcohol in the presence of an alkali, usually sodium hydroxide. Presumably, alkali cellulose is formed as an intermediate product. The extent of etherification is determined by the reaction temperature and the relative proportions of cellulose, alkali, etherifying agent and water in the reaction mixture. Commercially, the methyl, carboxymethyl and hydroxyethyl ethers are produced only in the low-substitution types which are soluble in water or in dilute solutions of an alkali. The preparation of the hydroxyethyl ether is unique in that it may be carried out by treatment of alkali cellulose either with ethylene chlorohydrin or with ethylene oxide. Carboxymethyl cellulose is prepared by treating alkali cellulose with sodium chloroacetate. Carboxymethyl cellulose will dissolve completely in water if some or all of its carboxyl groups are neutralized by NaOH, KOH or NH_4OH. All of the ethyl and benzyl ethers of cellulose produced commercially are of the types which are soluble in organic solvents; *i.e.*, with substitution more than 2.0. Ethyl cellulose possesses good resistance to acids and alkalies, high flexibility at low temperature, good electrical properties, solubility in a wide range of solvents and ready compatibility with many resins and plasticizers. These properties have won for ethyl cellulose wide use in protective coatings and plastics. Benzyl cellulose has not attained wide use because of its poor stability on exposure to light or to the action of oxygen at elevated temperatures.

Cellulose Addition Compounds.—Cellulose has the ability to form addition compounds with a variety of reagents. Although some investigators believe that the formation of alkali cellulose is a physical process, others believe that the mode of reaction of alkali cellulose in etherification indicates that it is a compound of the alcoholate type. (A true alkoxide, sodium cellulosate, is formed when cellulose is treated with a solution of sodium or sodamide in liquid ammonia.) However, the most widely accepted view is that alkali cellulose is an addition compound of the type $(C_6H_{10}O_5)_x.(NaOH)_y$. The results of X-ray analysis indicate that cellulose may form several different addition compounds with alkali, the compositions of which are determined by the type of cellulose used, the alkali concentration and the temperature. Treatment with aqueous solutions of alkalies (usually sodium hydroxide) has two important practical applications: (1) the modification of the physical and chemical properties of fibres, as in mercerization; and (2) the preparation of alkali cellulose as an intermediate in the manufacture of viscose and cellulose ethers. The ability of aqueous solutions of cuprammonium hydroxide and of strong acids to dissolve cellulose seems to depend on the formation of addition compounds. So-called cuprammonium rayon is prepared by extruding a cuprammonium hydroxide solution of cellulose in the form of filaments into an acid precipitating bath where the cellulose is regenerated.

Uses of Cellulose and Derivatives.—The mere mention of such products as rayon, cellophane, plastics and lacquers suffices to recall the enormous development which took place after 1920 in industries based on cellulose and its derivatives. However, the principal industrial applications of cellulose and its derivatives are so numerous and varied that they can be only summarized here:

Purified Natural Cellulose Fibres

Textiles.—Cotton is the natural fibre most widely used; flax and ramie are used to a much smaller extent.

Paper.—Purified fibres for papermaking are obtained from wood, grasses and straws, seed hairs (cotton rags and cotton linters) and bast fibres (flax).

Miscellaneous.—Vulcanized fibre, plastics fillers, filtering media and surgical cotton.

Regenerated Cellulose and Cellulose Derivatives

Lacquers.—Nitrocellulose lacquers are used for spray-coating automobiles, aeroplanes and furniture; and for dip-coating hardware, brush handles and other mass production items. Cellulose acetate propionate and cellulose acetate butyrate are used in clear metal finishes for outdoor use. Ethyl cellulose is used in coatings for ignition cables in automobile and aeroplane motors and other coatings requiring flexibility at low temperatures.

Plastics.—Nitrocellulose plastics (celluloid) have the best combination of physical properties, apart from heat sensitivity and flammability, of all the thermoplastic materials; large volume uses are spectacles frames and sanitary supplies. Cellulose acetate is used widely in making plastics by injection moulding and where flame resistance is important; *e.g.*, in motor housings and electric light ornaments. Cellulose acetate butyrate plastics are used where water resistance and dimensional stability are important; *e.g.*, in steering wheels and various types of piping. Ethyl cellulose plastics are tough over the widest range of temperature and are used in hammer heads and flashlights.

Rayon.—Viscose rayon, cellulose acetate rayon and cuprammonium rayon.

Films and Foils.—Nitrocellulose is used in commercial motion-picture film, X-ray film and microfilm for duplication of records, etc. Cellulose acetate propionate and cellulose acetate butyrate films are used where high dimensional stability is required; *e.g.*, aerial mapping. Thin sheets of regenerated cellulose (cellophane), cellulose acetate and ethyl cellulose are used for merchandise packaging. Regenerated cellulose is made from nitrocellulose for the production of sausage casings.

Textiles.—Artificial leather is made by coating cotton fabrics with solutions containing nitrocellulose and other ingredients. Aircraft fabric coatings may contain nitrocellulose, high-substitution cellulose acetate, cellulose acetate butyrate or cellulose acetate propionate. Flexible finishes on garment and upholstery leathers are produced with nitrocellulose lacquer emulsions. Hydroxyethyl cellulose and sodium carboxymethyl cellulose are used in textile sizes. Sodium carboxymethyl cellulose is also used as a detergent aid in textile washing.

Coated Paper and Cellophane.—Lacquer coatings containing nitrocellulose or other cellulose derivatives improve the grease and oil resistance, washability and electrical properties of paper. The moisture-proof coating on cellophane contains nitrocellulose and a small amount of wax. Paper disks coated with ethyl cellulose are used for sound recording in the home. Methyl cellulose is used to greaseproof paper. Sodium carboxymethyl cellulose is used in special papers because it improves fibre bonding.

Adhesives.—Cellulose derivatives are used in a wide variety of special adhesives.

Explosives.—Nitrocellulose is a minor ingredient in blasting gelatin and the major ingredient in smokeless powders, including rocket powder.

Thickening Agents and Protective Colloids.—Methyl cellulose and sodium carboxymethyl cellulose are used to increase the viscosity of certain food products, textile finishes and printing pastes, latex dispersions and paints.

CELSIUS, ANDERS (1701–1744), Swedish astronomer, was born on Nov. 27, 1701, in Uppsala, where he was professor of astronomy (1730–44). At Nuremberg he published in 1733 a collection of 316 observations of the aurora borealis made by himself and others 1716–32. In Paris he advocated the measurement of an arc of the meridian in Lapland, and took part, in 1736, in the expedition organized for the purpose by the French academy. Six years later he described the centigrade thermometer in a paper read before the Swedish Academy of Sciences (*see* THERMOMETRY). Celsius died at Uppsala on April 25, 1744. He wrote: *Nova Methodus distantiam solis a terra determinandi* (1730); *De Observationibus pro figura telluris determinanda* (1738); besides many less important works. The centigrade thermometer is often called

the Celsius thermometer, as other thermometers are named after Gabriel Fahrenheit and René de Réaumur.

See W. Ostwald's *Klassiker der exacten Wissenschaften*, no. 57 (Leipzig, 1904), where Celsius's memoir on the thermometric scale is given in German with critical and biographical notes.

CELSIUS SCALE: *see* THERMOMETRY.

CELSUS (*c.* A.D. 178), an eclectic Platonist and opponent of Christianity known mainly through the reputation of his work, *The True Word* (or *Account*; *ἀληθὴς λόγος*), brought to light in 248 by Origen who in his *Against Celsus* quotes, paraphrases and reproduces about nine-tenths of it. On internal evidence the work seems to be of Alexandrian origin and to date between 176–180.

Its attack on Christianity is opened by a rehearsal of Jewish taunts levelled at the Christians. Jesus was the natural son of Mary and Joseph. He did not convince even His own countrymen. His companions as well as His poverty were inconsistent with divine dignity. The Incarnation is absurd, for God stands in no special relation to man as against animals. Christ's miracles, like His resurrection, were inventions of His disciples. The Christians lack unity among themselves and their teachers have no power over educated men. Their doctrine comes from Plato and the Stoics, especially their belief in the future life and the spirituality of God. Their resurrection of the body is a corruption of the doctrine of transmigration and ignores the fact that matter is evil. Celsus ends his work by inviting the Christians to join the religion of the majority, to become good citizens, to give thanks to the powers of nature and to abandon the idea of establishing the universal rule of their doctrines. His work, which shows the strength of the church in his day, is conspicuous for its lack of bitterness against the Christians, its recognition of the abuses of paganism, and its knowledge of the Old Testament and the Synoptic Gospels and also of the gnostic writings. Echoes of it are found in Tertullian and Marcus Minucius Felix (*see* MINUCIUS FELIX, MARCUS), but it lay forgotten until Origen gave it new life.

Celsus was not a professed philosopher but a man of the world whose religion was the empire. His keen mind combined an intimate knowledge and appreciation of the various national religions and mythologies with many genuine moral convictions as well as a sceptical tendency. For him, philosophy alone could impart some notion of the Father of the universe, a notion which the elect soul must develop.

Keim, *Celsus Wahres Wort* (1873). *See* also J. Patrick, *The Apology of Origen* (1829); L. Rougier, *Celse* (Paris, 1925); F. S. Muth, *Der Kampf des heidnischen Philosophen Celsus gegen das Christentum* (Mainz, 1899); A. Harnack *Gesch. der altchristlichen Lit. I;* and Herzog, *Realencyclopädie.*

CELT or KELT, the generic name of an ancient people, the bulk of whom inhabited the central and western parts of Europe. (For the sense of a primitive stone tool, *see* the separate article, CELT.) Much confusion has arisen from the inaccurate use of the terms Celt and Celtic. It is the practice to speak of rather short and dark-complexioned Celtic-speaking people of France, Great Britain and Ireland as Celts, although the ancient writers seem to have applied the term Celt chiefly to folk of great stature and with fair hair and blue or gray eyes.

The ancient writers regarded as homogeneous all the fair-haired peoples dwelling north of the Alps, the Greeks terming them all *Keltoi.* Physically they fall into two loosely-divided groups, which shade off into each other. The first of these is restricted to northwestern Europe, having its chief seat in Scandinavia. It is distinguished by a long head, a long face, a narrow aquiline nose, blue eyes, very light hair and great stature. Those are the peoples usually termed Nordic. The other group is marked by a round head, a broad face, a nose often rather broad and heavy, hazel-gray eyes, light chestnut hair; they are thick-set and of medium height. This race is often termed Celtic or Alpine from the fact of its occurrence all along the great mountain chain from southwest France, in Savoy, in Switzerland, the Po valley and Tirol, as well as in Auvergne, Brittany, Normandy, Burgundy, the Ardennes and the Vosges. It thus stands geographically and in physical features between the Nordic type of Scandinavian and the so-called Mediterranean race with its long head, long face, its rather broad nose, dark brown or black hair, dark eyes and slender form, and medium height. In the Alps and the Danube valley some of the Celts or their forefathers had dwelt from the Stone Age. But it was during the development of the La Tène culture that the Celts attained their maximum power, and it was the La Tène period (500 B.C.–A.D 1) that witnessed the tremendous and remarkable expansion of these people from their homeland in central Europe. Much of their power has been ascribed to great skill in metallurgy, especially in regard to the working of the native iron resources.

The beginning of the 3rd century B.C. was the period of the greatest Celtic movement, but the expansion had no doubt begun long before that period. One of the earliest advances was directed against the Mediterranean coast of France, and at much the same time other bands of the Celts spread southward into Spain, penetrating into that country as far south as Gades (Cadiz), some tribes (*e.g.*, Turdentani and Turduli) forming permanent settlements and being still powerful there in Roman times; and in northern central Spain, from the mixture of Celts with the native Iberians, the population henceforward was called Celtiberian. About this time also took place a great invasion of Italy; Segovisus and Bellovisus, the nephews of Ambigatus, led armies through Switzerland, and over the Brenner and by the Maritime Alps, respectively (Livy, v, 34). The tribes who sent some of their numbers to invade Italy and settle there were the Bituriges, Arverni, Senones, Aedui, Ambarri, Carnuti and Aulerci.

Certain material remains found in north Italy (*e.g.*, at Sesto Calende) may belong to this invasion. The next great wave of Celts recorded swept down on north Italy shortly before 400 B.C. These invaders broke up the Etruscan power in a few years, and even occupied Rome after the disaster on the Allia (390 B.C.). Bought off by gold they withdrew from Rome, but they continued to hold a great part of northern Italy, extending as far south as Sena Gallica (*Sinigaglia*), and henceforward they were a standing source of danger to Rome, especially in the Samnite Wars, until at last they were either subdued or expelled (*e.g.*, the Boii from the plains of the Po). At the same time as the invasion of Italy they had made fresh descents into the Danube valley and the upper Balkan, and perhaps may have pushed into southern Russia, but at this time they never made their way into Greece, though the Athenian ladies copied the style of hair and dress of the Cimbrian women. About 280 B.C. the Celts gathered a great host at the head of the Adriatic, and accompanied by the Illyrian tribe of Autariatae, they overthrew the Macedonians, overran Thessaly, and invaded Phocis in order to sack Delphi, but they were finally repulsed, chiefly by the efforts of the Aetolians (279 B.C.). The remnant of those who returned from Greece joined that part of their army which had remained in Thrace, and marched for the Hellespont. There some of their number settled near Byzantium, having conquered the native Thracians, and made Tyle their capital. The Byzantines had to pay them a yearly tribute of 80 talents until, on the death of the Gallic king Cavarus (some time after 220 B.C.), they were annihilated by the Thracians. The main body of the Gauls who had marched to the Hellespont crossed it under the leadership of Leonnorius and Lutarius. Straightway they overran the greater part of Asia Minor, and laid under tribute all west of Taurus, even the Seleucid kings. At last Attalus, king of Pergamum, defeated them in a series of battles commemorated on the Pergamene sculptures, and thereafter they were confined to a strip of land in the interior of Asia Minor, the Galatia of history. Their three tribes—Trocmi, Tolistobogians and Tectosages—submitted to Rome (189 B.C.), but they remained autonomous till the death of their king Amyntas, when Augustus erected Galatia into a province. Their descendants were probably St. Paul's "foolish Galatians" (*see* GALATIA). Nor was it only toward the south and the Hellespont that the Celtic tide ever set. They passed eastward to the Danube mouth and into southern Russia, as far as the Sea of Azov, mingling with the Scythians, as is proved by the name Celtoscyths. Mithridates VI of Pontus seems to have negotiated with them to gain their aid against Rome, and Bituitus, a Gallic mercenary, was with him at his death.

The Celts moved westward likewise and two divisions of them reached the British Isles, namely the Brythons and the Goidels. The Brythons crossed the channel and established themselves in England and Wales but the Goidels, probably in the 4th century B.C., passed directly from the mouth of the Loire to Ireland where they quickly became a ruling caste. At a much later period there were settlements of Goidels from Ireland on the western fringe of England, Wales and Scotland. The Celtic invasions of the British Isles are in all probability to be correlated with the advent of the La Tène culture (though this is a disputed point), and it is thought to be unlikely that the invaders came over in large migrating hordes that displaced the older population. It is more probable that the new Celtic strain was quickly merged in the native races and that the principal result of the invasion was that the Celtic overlords imposed the Celtic language on the indigenous folk.

CELT, as once used by the British and French archaeologists, described the hatchets, adzes or chisels of chipped or shaped stone used by primitive man. The word is variously derived from the Welsh *cellt,* a flintstone (the material of which the weapons are chiefly made, though celts of basalt felstone and jade are found), from being supposed to be the implement peculiar to the Celtic peoples; or, more probably, from a Low Latin word *celtis,* a chisel. The term is somewhat loosely applied to metal as well as stone axeheads. In general form, stone celts approach an oval in section, with sides more or less straight and one end broader and sharper than the other. In length they vary from about 2 to as much as 16 in. Some were fixed in wooden handles, and in the later stone adzes, holes are sometimes found pierced to receive the handles.

The term celt has been largely superseded by axe, though it is by no means certain that all celts were axes. Some, such as the larger ones of ground stone, may well have been used in agriculture for moving the soil. Many were doubtless mounted as adzes, particularly those of the shoe-last type (*Schuhlastenbeil*), which have a very wide European distribution from the Balkans to Scandinavia.

Bronze celts are found in Europe, in Siberia, Burma (the Shan States) and China. They are flat, flanged, winged and socketed. An intermediate form is called palstave; and it has been suggested that the socketed celt was derived from the palstave by a natural transition, the invention being attributed to the people of the Lausitz culture of Germany. It is equally possible that the socketed celt was suggested by the beating over of the wings of the winged celt of Switzerland and Bavaria. Both explanations may be correct. The socket itself had been independently invented in England in the early Bronze Age, where it was applied to the spearhead.

In the west of England the country folks believe that the weapons fell originally from the sky as thunderbolts, and that the water in which they are boiled is a specific for rheumatism. In the north and in Scotland they are safeguards against cattle diseases. In Brittany a stone celt is thrown into a well to purify the water. In Sweden they are regarded as a protection against lightning. In Norway the belief is that, if they are genuine thunderbolts, a thread tied round them when placed on hot coals will not burn but will become moist. In Germany, Spain and Italy, the same beliefs prevailed. In Japan the stones are accounted of medicinal value, while in Burma and Assam they are regarded as thunderbolts and as infallible specifics for ophthalmia. In Africa they are the weapons of the Thunder God. In India and among the Greeks the hatchet appears to have had a sacred importance, doubtlessly derived from the universal superstitious awe with which these weapons of prehistoric man were regarded.

CELTES, KONRAD (1459–1508), German humanist and Latin poet, was born at Wipfeld, near Schweinfurt. After studying at Heidelberg, Celtes led the wandering life of a scholar of the Renaissance, teaching in various universities and everywhere establishing learned societies on the model of the academy of Pomponius Laetus at Rome. Among these was the *Sodalitas litteraria Rhenana* or *Celtica* at Mainz (1491). In 1486 he published his first book, *Ars versificandi et carminum,* which gained him the honour of being crowned as the first poet laureate of Germany, the ceremony being performed by the emperor Frederick III at the diet of Nuermberg in 1487. In 1497 he was appointed by the emperor Maximilian I to the post of professor of poetry and rhetoric at Vienna, and in 1502 was made head of the new Collegium Poetarum et Mathematicorum, with the right of conferring the laureateship. He did much to introduce system into the methods of teaching, to purify the Latin of learned intercourse, and to further the study of the classics, especially the Greek. But he was more than a mere classicist of the Renaissance. He was keenly interested in history and topography, especially in that of his native country. It was he who first unearthed (in the convent of St. Emmeran at Regensburg) the Latin poems of the nun Hrosvitha of Gandersheim, of which he published an edition (Nuermberg, 1501). He also published an historical poem, *Ligurinus sive de rebus gestis Frederici primi imperatoris libri x* (Augsburg, 1507), and the map of the Roman empire known as the *Tabula Peutingeriana* (after Konrad Peutinger, to whom he left it). He projected a great work on Germany; but of this only the *Germania generalis* and an historical work in prose, *De origine, situ, moribus et institutis Nurimbergae libellus,* appeared. As a writer of Latin verse Celtes far surpassed any of his predecessors. His epigrams, edited by Hartfelder, were published at Berlin in 1881. His editions of the classics are now, of course, out of date.

For a full list of Celtes's works *see* Engelbert Klüpfel, *De vita et scriptis Conradi Celtis* (Freiburg, 1827); Johann Aschbach, *Die früheren Wanderjahre des Conrad Celtes* (1869); Hartmann, *Konrad Celtes in Nürnberg* (Nuermberg, 1889).

CELTIBERIA, a term used by Greek and Roman writers to denote sometimes the whole northeast of Spain, and sometimes the northeast part of the central plateau. The latter was the correct use. The Celtiberi were the most warlike people in Spain and for a long time offered a stubborn resistance to the Romans. They served both Carthaginians and Romans as mercenaries, and Livy (xxiv, 49), states that they were the first mercenaries in the Roman army. In 179 B.C. the whole country was subdued by T. Sempronius Gracchus, who by his generous treatment of the vanquished gained their esteem and affection. In 153 they again revolted and were not finally overcome until the capture of Numantia by Scipio the younger (133 B.C.). After the fall of Numantia, and still more after the death of Sertorius (72 B.C.), the Celtiberians became gradually romanized, and town life grew up among their valleys. Clunia, for instance, became a Roman municipality, and ruins of its walls gates and theatre testify to its civilization; Bilbilis (Bambola), another municipality, was the birthplace of Martial.

The Celtiberians may have been descendants of Celtic immigrants from Gaul into Iberia (Spain), or a mixed race of Celts and Spaniards (Iberians); that a strong Celtic element existed in Spain is proved both by numerous traditions and by the more trustworthy evidence of place names.

Their country was rough and unfruitful as a whole (barley, however, was cultivated), being chiefly used for the pasture of sheep. Its inhabitants either led a nomadic life or occupied small villages; large towns were few. Their infantry and cavalry were both excellent. They carried double-edged swords and short daggers for use hand to hand; their defensive armour was a light Gallic shield, or a round wicker buckler, and greaves of felt around their legs. They wore brazen helmets with purple crests, and rough-haired black cloaks, in which they slept on the bare ground. They were said to offer sacrifice to a nameless god at the time of the full moon, when all the household danced together before the doors of the houses.

Although cruel to their enemies, they were hospitable to strangers. They ate meat of all kinds, and drank a kind of mead.

E. Hübner's article in Pauly-Wissowa's *Realencyklopädie*, iii (1886–93), collects all the ancient references.

CELTIC LANGUAGES. The Celtic languages form one group of the Indo-European family of languages, intermediate between the Italic and Teutonic groups, but distinguished from these and other branches of the family by certain well-marked characteristics, the most notable of which are the loss of initial and inter-vocalic *p*, and the change of Indo-European *ē* to *ī*, the Indo-European labialized velar *gv* is represented by *b*, while the medial aspirates *bh, dh, gh* result in simple voiced stops. Indo-European sonants *r* and *l* become *ri, li*. The initial mutations which are so characteristic of the living languages arose after the Romans had left Britain. The Celtic languages and the Italic dialects stand in a close relationship to one another. The features common to both Celtic and Italic are: (1) the genative singular ending *-ī* of masculine and neuter stems in *o;* (2) verbal nouns in *-tion;* (3) the *b-* future; (4) the passive formation in *-r*.

The various Celtic dialects are: (1) Gaulish; (2) Goidelic, including Irish, Scottish Gaelic, and Manx; (3) Brythonic, including Welsh, Breton, and Cornish. Gaulish and Brythonic change the Indo-European labialized velar guttural *qu* to *p*, while the Goidelic dialects retain the *qu*, which later gives up the labial element and becomes *k*. (*See* CORNISH LANGUAGE; GAELIC LANGUAGE; INDO-EUROPEANS; MANX LANGUAGE AND LITERATURE; WELSH LANGUAGE AND LITERATURE.)

Pedersen (Göttingen, 1908); H. Zimmer, "Die Kelt. Litteraturen" in *Die Kultur d. Gegenwart* (Berlin and Leipzig, 1909); Whitley Stokes and A. Bezzenberger, *Wortschatz der keltischen sprachenheit* (Göttingen, 1894); A. Meillet and M. Cohen, *Les Langues du Monde* (1924).

CELTIC LITERATURE: *see* BRETON LITERATURE; CORNISH LANGUAGE; IRISH LITERATURE; SCOTTISH LITERATURE; WELSH LANGUAGE AND LITERATURE.

CELTIUM is the name given by G. Urbain and A. Dauvillier to the element of atomic number 72, for which the former obtained some evidence from X-ray spectra in 1911. Their claim to have discovered this element was, however, disputed by D. Coster and G. Hevesy (1923) who named it *Hafnium*, under which heading it is described. Of the resulting polemical papers only a few are suggested for reference.

CEMBAL D'AMORE or CEMBAL D'AMOUR, a keyboard instrument invented by the famous organ and clavièr maker Gottfried Silbermann, who was later so prominently identified with the earlier pianofortes. It was a kind of clavichord with strings of double the usual length, and its other mechanism modified to correspond, but it was not a success.

CEMBALO or CIMBALO, the Italian names for a dulcimer (*cf.* cymbal); whence, in due course, clavicembalo for a pianoforte, otherwise a keyed dulcimer. Hence, too, the frequent use of the word cembalo in earlier days in the case of pianoforte music; as used in such cases it was merely a contraction of clavicembalo. (*See* DULCIMER.)

CEMENT. The word cement apparently was first used of a mixture of broken stone, tiles, etc., with some binding material, and later it was used of a material capable of adhering to, and uniting into a cohesive mass, portions of substances not in themselves adhesive. The use of cementing material dates from very early days, and it is probable that adhesive clay was one of the first materials used for uniting stones, etc. Bitumen probably was also used for the same purpose, while the use of burned gypsum, and also lime, dates back to the time of the Egyptians.

In its widest sense the word cement includes an infinite variety of materials, and ranges from the clay used to bind stones and other materials together to form the natives' huts in tropical countries, or the clay in the sand used by small boys to make sand models, up to the modern rapid hardening cements which are capable of binding three times their own weight of sand together in such a way that, at the end of 24 hr., they will stand a compression of several thousand pounds per square inch. It also includes those materials which join individual crystals together to form masses of rock, etc., such as the cementitious material which joins the grains of sand together in a sandstone, and ultimately merges into glues, solders and adhesives in general, between which there is no sharply defined line of demarcation.

In its more restricted sense, particularly if it is unqualified and used in connection with building and engineering, the word practically always means portland cement, as this is by far the most important cement used at the present time, the world's output amounting to millions of tons per annum. A fairly full description of this cement is therefore justified, and a brief description of other cements will be given toward the end of this article.

Portland Cement.—Portland cement is made by burning a mixture of calcareous and argillaceous material to clinkering temperature, and grinding the resulting clinker. The mixture may be a natural one (such as the marls) or an artificial one (such as chalk or limestone) for the calcareous material, and clay or shale for the argillaceous material. The binding qualities of modern cements are very considerable, and it is possible to make good concrete from properly graded sand and ballast with the use of 1 part of cement to 12, or more, parts of aggregate; but as it is not always possible in practice to obtain a thorough distribution of cement throughout the mass, it is customary to use a larger proportion of cement; *e.g.*, 1:3:5 parts of cement, sand and gravel; and for a better quality concrete, 1 part of cement to 2 or 3 parts of sand, and 3 or 4 parts of gravel. A good cement mortar can be made from 1 part of cement to 4 or 5 parts of clean sharp sand, free from clay. If the mixture is too rich (*e.g.*, equal parts of sand and cement) there is danger of cracks due to shrinkage, and apart from this the extra strength gained by using a greater proportion of cement than 1 to 3 of sand is so small that the additional cost is not justified.

History.—Very little definite information about the preparation and uses of cement can be found before the 18th century. Various districts gained reputations for the special qualities of their lime cements, such as the power of setting hard under water, but the reasons for these special qualities were not known until the last century. John Smeaton was one of the first to make any serious attempt to grapple with the question of the cause of the varying hydraulic properties of different lime cements. In 1756, while engaged on the construction of the Eddystone lighthouse, he made a series of experiments to find the best cement capable of hardening under water. The result of these experiments revealed the fact that the best hydraulic limes were made from limestone containing an appreciable quantity of clay. This led to a number of investigators carrying out experiments. In 1796 Parker invented his Roman cement, which was made by "reducing to powder certain burned stones or argillaceous productions called 'noddles' of clay." This cement "will set . . . in 10 or 20 minutes either in or out of water." The raw materials for Roman cement were burned to just short of the vitrifying temperature, whereas for hydraulic lime the raw materials were heated to a much lower temperature, which was just sufficient to decompose the calcium carbonate. This was a distinct advance, as the overburned or vitrified pieces of lime had formerly been picked out and rejected as being useless for mortar.

Vicat, in 1813, made a series of experiments on the effect of adding different clays in varying proportions to slaked lime, and then burning the mixture. The success of these experiments led other investigators to try artificial mixtures of clay and calcareous materials and in 1822 Frost brought out his British cement, which was soon followed by Joseph Aspdin (1824) with portland cement. Both of these, however, were hydraulic limes, in that the mixtures were only calcined and not clinkered. Aspdin was apparently the first to use the word portland to define a particular type of cement, although Smeaton, over half a century earlier, had said that cement made from these materials would

"equal the best merchantable Portland stone in solidity and durability." His portland cement was, of course, quite different from modern portland cement, but nevertheless the colour and properties of concrete made from this cement were somewhat similar to Portland stone.

By this time (1820–30) works were springing up in various parts of the country where the raw materials were suitable; Parker's Roman cement was manufactured at Northfleet, Kent; British cement was made by Frost at Swanscombe; and the Aspdins were making portland cement at Wakefield and Gateshead. This portland cement, as mentioned above, was more of the nature of hydraulic lime; but about 1845 I. C. Johnson, who was then manager of Messrs. White & Sons' works at Swanscombe, Kent, produced a cement of the modern portland cement type, by burning the raw materials "with unusually strong heat until the mass was nearly vitrified," and this clinker, when finely ground, made a cement which was far in advance of the ordinary type produced at that time.

During the next few years many works started making true portland cement, both in Britain and in other countries. In France, Dupont and Demarle were delivering fairly large quantities of portland cement in 1850 from their works at Boulogne-sur-Mer and the demand continued to grow. Naturally with such a demand, and with such scanty knowledge as to the special requirements necessary for ensuring the production of good sound cement, a large quantity of inferior material came on to the market, and failures resulting from this gave the cement a doubtful reputation. Investigations for improving the quality of cement continued with moderate results. Grant's tests, in 1865, show an average tensile strength of 353.2 lb. for 2¼ sq.in. (1½ in. × 1½ in.) cement and sand briquettes (1:1) at seven days (157 lb. per sq.in.), while in 1878 a tensile strength of 500 lb. (2¼-in. briquettes), *i.e.*, 222 lb. per sq.in., was specified for briquettes made from 6 parts of cement to 10 parts of sharp sand. This may be compared with modern rapid-hardening cement, which, with 1 part of cement to 3 parts of standard sand, has a tensile strength of more than 500 lb., and sometimes more than 600 lb. per sq.in. after 24 hr.

Manufacture.—When cement was first made from stone noddles, as in Parker's method, the stone was placed in a bottle kiln or dome kiln ordinarily used for burning lime. When at a later date artificial mixtures of chalk and argillaceous materials were used, it was found that the best and most intimate mixtures were made by beating clay and chalk into a thin slip or slurry with water. This slurry was then allowed to stand in large settling tanks, or backs, until the material had settled, and the water was drawn off and the deposit dried and burned. The time taken for the settling and drying of the raw materials was so great that efforts were made to improve the kiln (which, of course, could only be fed with dry material) by utilizing the waste heat for drying the slurry. One of the first of these was the chamber kiln of I. C. Johnson, which consisted of a long horizontal chamber connected with the top of the ordinary kiln, so that the hot gases from the latter had to pass through the chamber on the way to the chimney stack. The liquid slurry, either from the backs or direct from the washmill, was placed on the floor of the chamber and was effectively dried by the hot gases passing over it, providing the layer of slurry was not too thick. The chamber had to be of considerable length in order to provide floor space to dry sufficient slurry for a full charge of the kiln, and improvements in the direction of shortening this were made by Batchelor and others, by providing two or three floors one above the other. Coke was used for burning the raw materials and ranged from 8 to 9 cwt. per ton of clinker. In 1870 Goreham patented his method of grinding his slurry with burr stones, thereby producing a better slurry and containing only 40%–42% of water, a proportion much less than was usual at that time, which, of course, facilitated drying. The construction of the bottle kiln, even in its improved form, the chamber kiln, necessitated intermittent firing, as each charge of fuel and dried slurry had to be built up by hand. Experiments with the object of doing away with this costly intermittent method led to the development of shaft kilns, with continuous burning of the raw material. The shaft kiln, as its name implies, consists of a vertical shaft, the top of which leads into a chimney. A few feet from the ground level removable bars are fixed across the shaft. On to these bars is placed a layer of coke, then alternate layers of dried slurry and coke until the kiln is filled. The coke at the bottom is fired, and this burns the raw material above it, while the hot gases pass through and heat the layers above. As the coke burns away the cement clinker drops on to the bars and heats the incoming air, while the burning zone rises to about half way up the shaft. The partly cooled clinker on the bars is removed from time to time and fresh layers of dried slurry and coke are put in on top. The process thus becomes continuous, and the loss of time in waiting for the kiln to heat up and cool down, together with the resultant loss of heat, which is unavoidable with the chamber kiln, is entirely overcome in the shaft kiln. Modifications of the shaft kiln were patented by Dietszch, Stein, Schneider and others, and the different types became known by the names of the patentees. The next improvement was the use of forced draught instead of natural induced draught from the chimneys, and tests on a standard Schneider kiln showed an increase in output from the normal 70 tons per week to 150 tons per week when using mechanical draught.

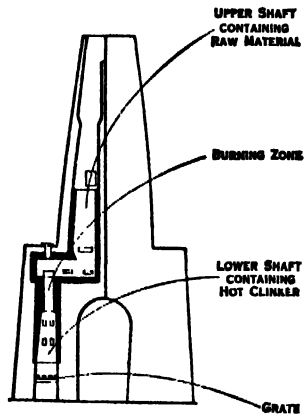

FIG. 1.—DIETSZCH SHAFT KILN

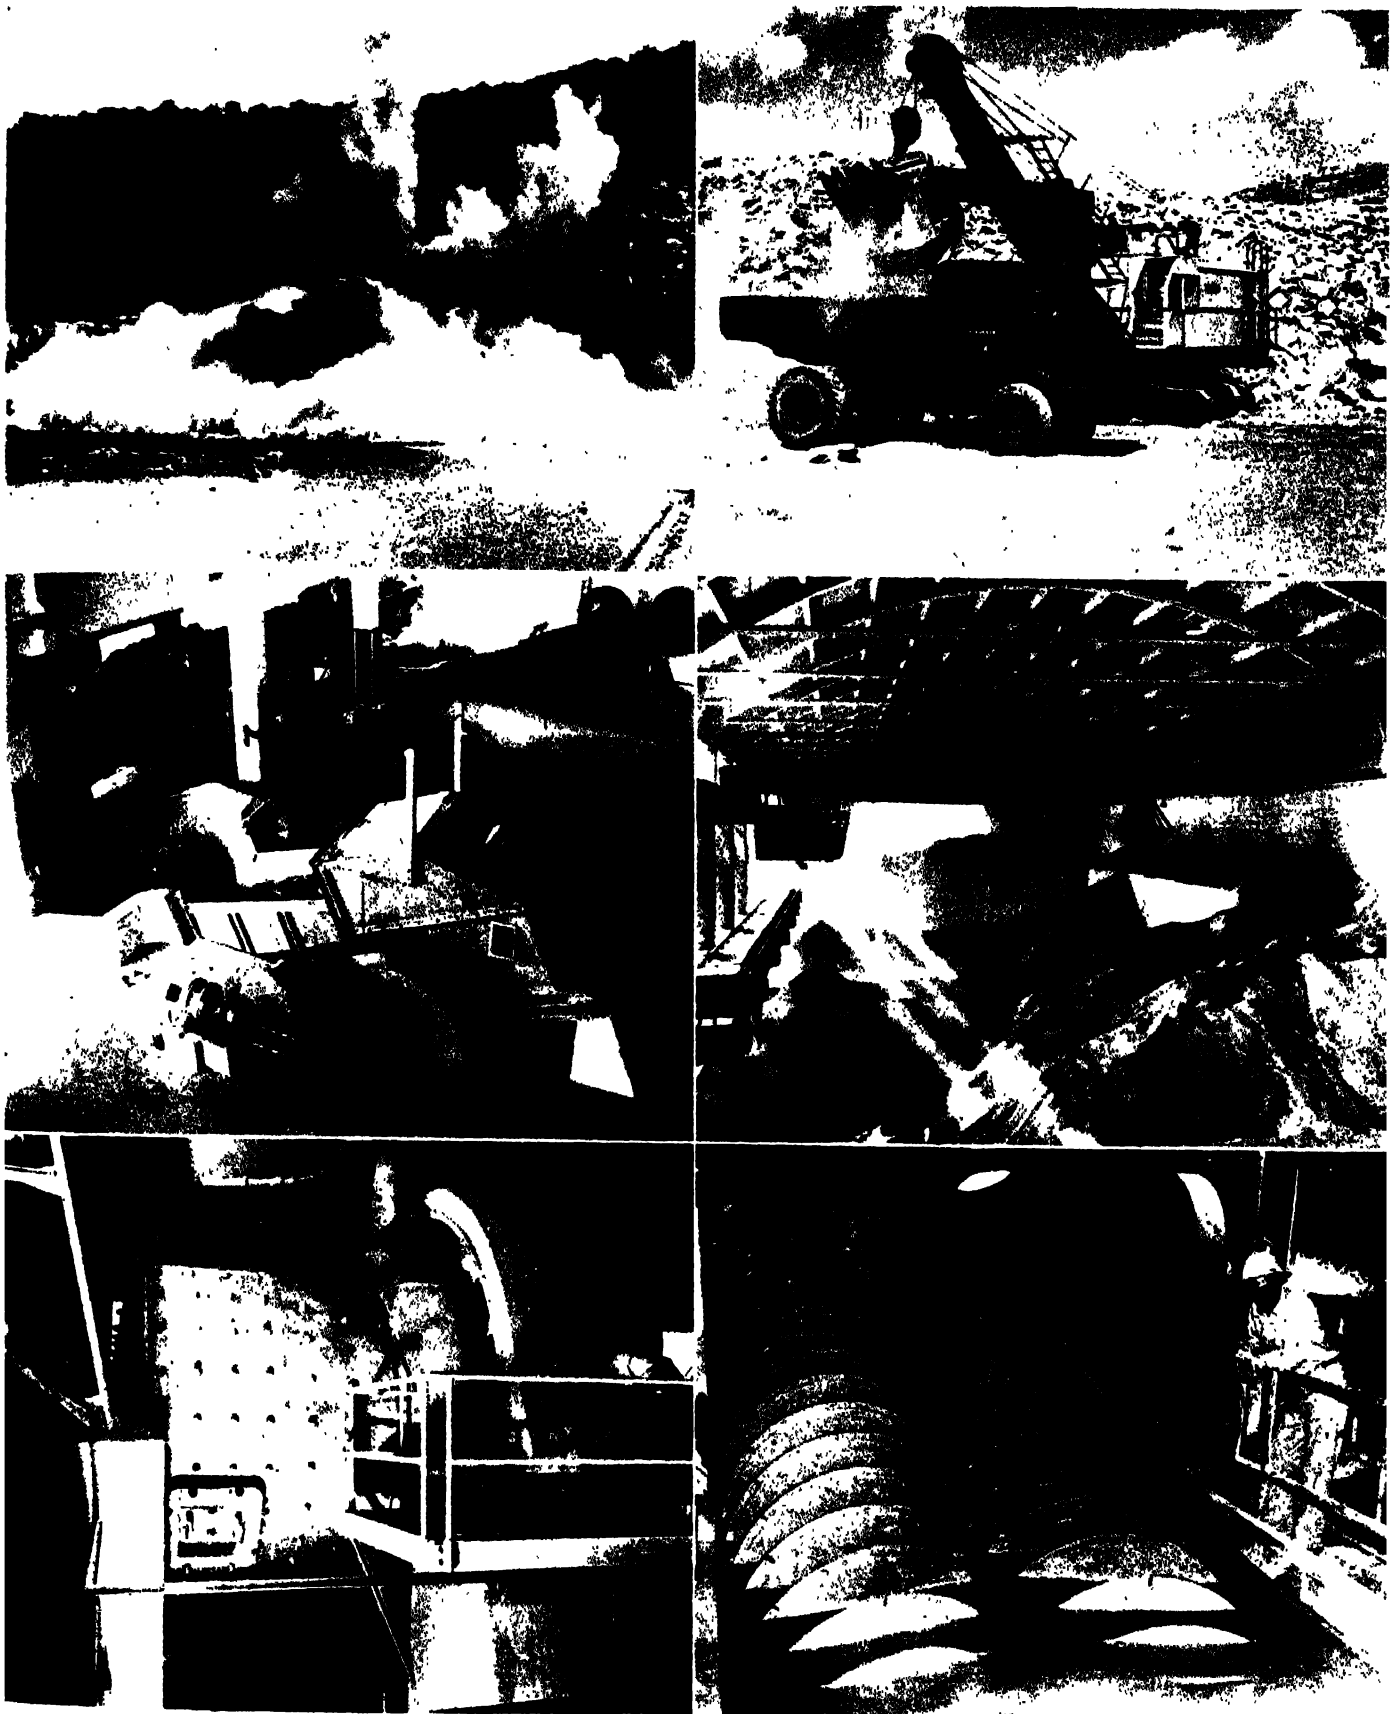

Fresh layers of coke and slurry are added from the top as soon as the coke at the bottom is burned away, thus keeping the burning process continuous

One of the weaknesses of the shaft kiln—or a fixed kiln—is the difficulty of ensuring even burning of the clinker, some of it being underburned while other portions were heavily clinkered, and various mechanical improvements have been made in the grate with the object of keeping the whole of the material in the kiln on the move by the continuous withdrawal of the clinker. The improvements in the shaft kiln reduced the quantity of fuel required from 70% to 80% of the weight of good clinker produced by the old kiln to 20% to 30% (dried slurry being used in both cases). This economy of fuel and the small amount of handling required, together with low capital cost, render the shaft kiln method suitable for use where the small output does not justify the cost of the rotary kiln.

Other methods of preventing the waste of heat resulting from the heating up and cooling of the old type of kiln were investigated. One of the most successful was the Hoffman ring kiln, which consisted of a number of kilns arranged in a ring around a central chimney. The flues from the kilns are so arranged that air, which is heated by being drawn through clinker which is cooling, is used for burning the fuel in the next kiln or two, and the hot gases are drawn through the other kilns to heat the raw materials before passing into the main flue. These ring kilns are very economical of fuel but require skilled hands for charging, and the labour costs are high.

Another method, which laid the foundations for the modern rotary kiln process, was devised by Thomas Russell Crampton, who in 1877 patented a method for burning "portland and other cements in revolving furnaces heated by the gases resulting from the combustion of coal or carbonaceous material" or "by the combustion of air and powdered carbonaceous material."

In 1885 Frederick Ransome patented a method of burning dry powdered materials in a rotating cylinder by means of which he hoped to obtain the finished product from the kiln in a powder form sufficiently fine for use without further grinding, evidently overlooking the fact that clinkering is an essential process in the manufacture of true portland cement. He also stated that the raw material might be fed in either at the chimney end of the kiln or at the firing end, which suggests that he had not appre-

ciated the full value of feeding the kiln at the end opposite to that used for burning the fuel. Further improvements were effected by F. W. S. Stokes who in 1888 patented a method of drying the slurry by passing the hot gases from the rotating kiln through a revolving drum on to the outside of which the slurry was fed. He also used another revolving drum for cooling the clinker, utilizing the waste heat for heating the air supplied to the fuel in the kiln. In 1895 and 1896 E. H. Hurry and H. J. Seaman obtained various patents for improvements in cooling the clinker, arrangements for using powdered coal with an air blast for burning, etc., and various other developments have been made with the rotary kiln, until it has very nearly displaced all others where a large output of portland cement clinker is required. Among the first rotary kilns erected was that at Arlesey (1887). This was 26 ft. long and 5 ft. in diameter, and forms an interesting comparison with those now in common use, which are 200 to 300 ft. long, and 8½ ft. to 12½ ft. in diameter.

Modern practice is to grind a mixture of suitable calcareous and argillaceous materials, either wet or dry, in such proportions as will give the correct composition to the finished cement. The wet ground material is pumped, in the form of a slurry containing about 40% water, into a series of large mixing tanks having a capacity of 1,000 to 2,000 tons of slurry, and from these it is pumped into the kiln. The dry ground raw material is carried by a conveyor to the storage bins, and from the bins it is fed into the kiln after having been damped to prevent too much dust being blown up the chimney. The raw material, either in the form of slurry or damp meal, enters the kiln at the top end close to the chimney and meets the oncoming hot gases. As the kiln revolves the raw materials fall down toward the clinkering zone, having been first dried by the hot gases, and then having the carbon dioxide driven off from the calcareous materials. In the clinkering zone, where the heat is maintained by the combustion of powdered coal carried in by a blast of air, the lime of the calcareous materials combines with the silica and alumina of the argillaceous materials, and at this stage they partially fuse or clinker together, an action which is facilitated by the alkalies and iron oxide, etc., in the materials. The partially fused product or cement clinker passes from the lower end of the kiln to the cooler, where it parts with some of its heat to the air going to the kiln. The clinker, with the addition of a little gypsum or water to regulate the setting time, is then ground in ball and tube mills to such a fineness that the finished product—portland cement—leaves a residue of less than 10%, usually 1% to 3%, on a sieve having 32,400 meshes to the square inch.

The raw materials consist of argillaceous or alumina and silica bearing materials and calcareous materials, the former including clay, shale, slate, etc., and some forms of slag, and the latter including chalk, limestone, marine shells, etc., while many materials such as marls, gault clays, cement rock, etc., contain natural mixtures of both the calcareous and argillaceous constituents.

The method of obtaining the raw materials will depend on whether they are hard or soft. With soft materials, such as clay, marl and soft chalk, a steam digger or scraper is used. After the overburden or top refuse material has been removed, a face is opened up in the material. The steam digger is brought up to this face, and the teeth of the digger bite into the material, and, on being lifted upward, break or cut away lumps which fall into the bucket. The bucket, which holds from ½ to 3 cu.yd. or more, is swung around and emptied into a truck which is then taken to the washmill. For very soft materials, such as mud or clay under water, a dredging machine—a form of chain bucket excavator—is used. For hard materials, such as limestone, etc., the rock is blasted with an explosive such as gelignite, which will break it into pieces sufficiently small for the crusher to take. If the pieces are too large they are very difficult to handle or break again, and it is in regulating the position and depth of the boreholes, and the size of the charge, that the good quarry foreman shows his skill in obtaining the greatest quantity of loose rock of the right size with the least cost. The broken rock lying at the base of the quarry is picked up by a power shovel or a grab, taking up 3 cu.yd. or more at a time, put into trucks and taken to the mills.

Grinding Raw Materials.—The methods used depend on whether the materials are soft or hard. Soft materials are usually washed down with water until they form a slurry of the consistence of cream, containing about 40% water. The trucks of marl or chalk and clay are tipped into a washmill, which consists of a large circular tank of concrete about 14 ft. or more in diameter, with baffles and slotted screens ($\frac{1}{8}$ in. to $\frac{3}{16}$ in. slots) let into the sides. Water is allowed to run into the mill and a number of harrows suspended on chains from radial arms from the centre of the mill are caused to revolve at a rapid rate. These harrows break up the large pieces of chalk, etc., and by dashing the raw materials, suspended in the water, against the screens and baffles, break up the clay and chalk into such fine particles that about 98% will pass through a sieve having 180 meshes to the linear inch. If, owing to the presence of coarse particles of sand, etc., the slurry is too coarse, it may be necessary to finish it off in a tube mill. In the U.S. the 200-mesh sieve is commonly used.

Hard materials are first put through a crusher which may be of the jaw type, in which the stone is fed in between two steel jaws set at an angle, one of which moves backward and forward with a rocking motion, or through a gyratory crusher, in which the gyratory motion of a central jaw causes a crushing action against an outer jaw, or through some other form of crusher suitable for large stone. The crushed stone is fed into smaller crushers which may be one of the above types, or a hammer mill in which rods with hinged hammer heads are allowed to swing around rapidly and break the stone against stationary bars on the outer edge of the mill, or if the material is sufficiently soft it may be fed into crushing rolls.

From this fine crushing the small stone is taken by a conveyor to the tube mills, and then to the kiln. The process differs according to whether the dry process or the wet process is used. In the dry process the limestone and shale, etc., are fed into the mills from the weighing machines or feed tables (which regulate the quantity) in such proportions as will give a finished product of the correct composition. The mills may be of various types. In the ball and tube mill, separate or combined, steel balls falling over each other in a revolving cylinder have a pounding or hammering action on the particles of stone between the balls. In the centrifugal type of mill a heavy mass of steel is caused to revolve rapidly, and centrifugal force causes it to press against a stationary ring and exerts both a crushing and grinding action on the stone between the revolving weight and the ring. In the Fuller mill the

revolving weights are large steel balls, in the Griffin mills they are large pestles, while in mills of the Hercules, Huntingdon, Sturtevant and Kent types they consist of movable or swinging rolls.

The finely ground raw meal from the mills is passed into the storage bin, from which it is fed into the kiln, after being damped if necessary. From this point the treatment is the same as the wet process. The advantage of the dry process is a saving of fuel, and of water, if the water supply is limited. Also, where waste-heat boilers are installed, more heat is available for power generation. For a long time it was generally believed that dry raw materials could not be mixed sufficiently well to ensure even composition, but since the introduction of compressed air devices for conveying these materials (cement pumps), and the floating of the materials in storage bins by use of compressed air, a state of practical fluidity is obtained which results in dry blending as thorough as can be accomplished by the wet process.

In the wet process the limestone and shale from the feed tables, or weighing machines, are fed into the ball mill and then the tube mill, or into a compound mill where the two are combined, and the requisite quantity of water added at the same time. The normal slurry coming from the mills contains about 40% water, and leaves less than 2% residue on a sieve having 180 meshes to the linear inch, but as it occasionally contains coarse particles which have passed through the mills, it is customary to put the slurry through a separator, usually of a centrifugal type, which rejects all the coarse particles. The slurry from the sump of the washmill, in the case of soft materials, the tube mill in the case of hard materials, or the separator, is pumped to the mixers, which are large tanks capable of holding 1,000 to 2,000 tons of slurry. These mixers serve three purposes: (1) they allow corrections to be made in the composition of the slurry, (2) they overcome any temporary variation in the composition by dispersing it and mixing it with the large bulk, and (3) they give efficient storage, allowing the grinding plant to be shut down over the week end (and at night, if required) while the kiln continues to run. To prevent settlement in the tanks the slurry is continuously kept on the move.

This is done either mechanically by rotating arms with paddles, or by the release of compressed air in the bottom of the tank, which bubbles up through the slurry.

Until comparatively recently cement manufacturers obtained slurry mixtures entirely by blending natural raw materials. In 1934 a process of flotation, long employed in the concentration of ore, was adapted to the connection or beneficiation of limestones. In fine grinding rocks they are largely broken down into their mineralogical constituents such as calcite, quartz, mica, etc. By employing the principles of froth flotation the calcite can be floated off, so that a slurry containing originally perhaps only 40% calcium carbonate (lime material) can be concentrated to 75%. Similarly, excesses of silica, alumina, iron oxide, magnesium-bearing minerals such as mica, etc., may be separated and used, or discarded. The flotation process applied to cement raw materials has greatly widened possibilities of cement manufacture from rock deposits previously rejected. It also makes possible manufacture of various kinds of portland cement—that is cements adapted for special purposes such as low heat of hydration, sulphate resisting, etc.

From the mixers the slurry is pumped to a small tank at the top end of the kiln, from which it is fed into the kiln at such rate as the burner thinks necessary. The usual method of doing this is by a spoon feed, the revolving spoons dipping into the tank and delivering the slurry into the kiln. Occasionally the feed is regulated by a variable orifice leading into a delivery pipe. Whichever of these two methods is used, it is the regular practice to keep the tank at constant level by overpumping and allowing the excess of slurry to run back to the mixer through an overflow pipe. Other methods, such as the spray feed and dewatering the slurry by means of vacuum filters, have been tried with some success.

Burning.—The most essential part of the manufacture of portland cement is the complete chemical combination of certain constituents; viz., silica, alumina and lime. The other constituents, particularly the iron oxide and alkalies, play their part but are subsidiary to the three main constituents. These readily combine at a high temperature, but at this temperature it is difficult to get the kiln lining to stand up, and therefore every means should be taken which will assist the chemical combination to take place at a somewhat lower temperature, and also prevent any excessive attack on the lining bricks. Fine grinding plays an important part in meeting the first of these two requirements, and the second is met by obtaining a coating of a more fusible slurry to adhere to the lining brick, and thus protect them.

The kiln itself consists of a cylindrical shell made of steel plates lined with fire bricks for nearly the whole of its length. The length varies from 150 ft. to 350 ft. or more, and the diameter from 8 ft. to 14 ft., usually with an enlarged diameter at the firing zone, so that the clinker may be allowed to soak at the high temperature. The kiln itself is carried on three to six tires, according to its length, and is driven by a gear ring usually fixed a little below the middle of the kiln. The expansion of the kiln is considerable, and therefore the tires and gear ring are not riveted directly on to the kiln, lest they be fractured, but are fixed to metal bands riveted at one end to the kiln, and are also supported by guide blocks. As the kiln is set at an angle usually of 1 in 25, the tendency of the kiln to slide down while revolving is counteracted by having the faces of the tires and the supporting rollers set at an angle. As a further precaution check rollers are fixed so that should the kiln slip down a little these rollers come into action on the side of the tires and stop the kiln from slipping off the supporting rollers. At the upper end, where the slurry or damp meal is fed in, the kiln passes into the dust chamber through a joint which is reasonably tight to prevent loss of draught, and the hot gases, having deposited a large portion of the dust, are led into the chimney.

Before the chimney, flues are sometimes installed leading under boilers where steam is generated for turbine-generator units which furnish sufficient power to operate the plant. Near cities and towns plants are frequently equipped with dust collectors, either mechanical or of electrical precipitation type. Otherwise dust losses may amount to 5% or more of the kiln output; and neighbours object to dust. The lower end of the kiln is fitted with a large adjustable hood, on rails, which allows access to the interior for relining, etc. The white hot clinker falls through an opening in the bottom of the hood into a clinker cooler. The old method of cooling was to allow the clinker to roll through a refractory-lined cylinder, similar to the kiln but smaller, open at the lower end. Later installations used air-quenching devices, usually an enclosed slowly moving grate, through which a blast of cold air was blown. It is quite generally believed, in the United States at least, that quickly cooled clinker is superior. The kiln is fired through a pipe opening, usually in the centre of the hood, with a mixture of pulverized coal, natural gas or oil, and air. This primary air is heated by being passed over or through the clinker. Secondary air to complete combustion is admitted through openings in or around the hood. Modern installations use heated primary air to dry the coal in the pulverizer as well as inject it into the kiln. Burning formerly depended largely on the judgment of the attendant (the burner) but indicating and recording instruments permit accurate control, and in the newest installations instrumental control of kiln speed, draft, and feed practically eliminate the personal equation of the burner.

Clinker Grinding.—The clinker as it comes from the kiln is in a fairly stable condition, and may be stored for months in the open if necessary without any appreciable deterioration. This, however, represents so much locked up capital, and it is therefore customary to grind the clinker soon after it is made. Very fresh clinker appears to be a little tougher than clinker which has been allowed to stand a week or two, and this sometimes affects the power required for grinding. The clinker from modern kilns is usually small enough to be fed directly into a ball mill or a high-speed mill, but if it is too large it is passed through a crusher first. As it is usually necessary to add a definite proportion of gypsum to the clinker in order to regulate the setting time of the cement, both the clinker and gypsum are passed over feed tables

before being mixed and fed into the mills. The feed tables are simple devices for regulating the quantity of any material passing over them in a given time and consist of a revolving table, fixed scrapers and a vertical feed pipe, with an adjustable collar, just above the centre of the feed table. The material falls in a heap in the centre of the table, and as it revolves a portion of the material is guided by the scrapers away from the heap to the edge of the table, from which it falls on to a conveyor and is taken to the mills. The heap in the centre is at once replenished from the feed pipe, and the size of the heap, and therefore the quantity removed by the scraper, is regulated by the height of the adjustable collar the feed pipe above the table.

The mills used for grinding the clinker are of the same types as those described for the grinding of the raw materials. The type most frequently used for clinker grinding in modern plant in Britain is the compound mill, which is usually 7 or 8 ft. in diameter and 30 to 40 ft. long.

The fineness of portland cement was formerly universally specified as percentages passing very fine mesh testing sieves, but there is a tendency to drop sieve sizes and specify specific surface area, which is the calculated surface area in square centimetres per gram.

Storing and Packing.—Finished cement from the grinding mills is conveyed to storage bins or silos by belt conveyors, screw conveyors, bucket elevators, or in recent installations by a screw conveyor-compressed air device known as a cement pump, which delivers through piping a steady flow of cement suspended in or made fluid by air. Storage bins are generally cylindrical reinforced-concrete silos, holding 12,000 to 15,000 bbl. (2,500 to 3,000 tons) each. Storage was originally considered desirable to season the cement. This is no longer essential with a properly made cement, but storage of as much as one-fourth to one-half the annual capacity of the plant is desirable in order to provide continuous and economic operation. Moreover, large purchasers demand that the cement be held and tested before shipment, and some tests require 30 days' time.

The cement is withdrawn from the silos by screw conveyors or cement pumps and conveyed to small bins serving packing machines, or is conveyed directly to spouts or pipes for bulk shipment in specially designed railway cars, barges and motor trucks. Most of the cement is packed in cotton or paper valve bags, which in the United States hold 94 lb. net, or approximately 1 cu.ft. of cement. The tops of the bags or sacks are tied or sealed before filling and a turned-in corner, or valve, on the bottom provides the opening for slipping the bag over the spout of the bag-packing machine. These machines utilize the principle that cement flows freely when the proper amount of compressed air is injected into the feeding device. A single operator can manipulate three to four loading spouts. The flow of cement into the bags is automatically cut off when the proper weight is reached, the material in the bag closes the corner valve, and the bag drops off to a belt conveyor below. The empty bags must be slipped over the filling spout by the operator. In one type of machine this is the only manual part of the operation. Cotton bags are returned to the cement manufacturer (a discount being allowed on the purchase price for their return), and are reused many times.

Cement for export is often packed in wooden barrels or steel containers, which stand on scales while being filled. Originally all cement was shipped in barrels, the standard U.S. barrel holding 376 lb. net. Four bags therefore are equivalent to one barrel. The fact that the trade marks or brands of the older cement companies are circular designs is because they were intended to be used on barrel heads.

Layout of Works.—For the purpose of economy and efficiency, considerable care must be exercised in the layout of the works, so that the raw materials and coal are delivered at the places where they are to be used, and the clinker and cement stores are in the proper position for the minimum handling of these materials.

Analysis and Tests.—Drafting specifications to insure quality of portland cement is complicated because qualities most desired are physical—workability, strength, durability, impermeability and density in the mortar and concrete made with cement—and these may be obtained with cements of various chemical compositions. After years of argument, the Cement committee of the American Society for Testing Materials by 1930 had reduced its specifications to simple form covering only the following factors: (1) chemical limits; (2) soundness; (3) time of setting; (4) tensile strength; (5) packaging and marking; (6) storage; (7) inspection; (8) rejection; (9) methods of testing.

The chemical limits are that the cement shall show on testing amounts not greater than indicated with the respective tolerances in the following table:

	Limits (%)	*Tolerances (%)*
Loss on ignition	4.00	0.25
Insoluble residue	0.85	0.15
Sulphuric anhydride (SiO_3)	2.00	0.10
Magnesia (MgO)	5.00	0.40

The A.S.T.M. soundness test consists of subjecting a pat of neat cement (cement mixed with water) to five hours' steaming. The pat must not distort, crack, check or disintegrate. A soundness test used by U.S. cement manufacturers in their own laboratories for control purposes, and one included in many specifications, consists of subjecting 1-in. square bars of neat cement, usually 10 in. long, to an autoclave test with steam at 350 lb. pressure for three hours. The bar should not disintegrate, or expand in length more than 1% (although no limit has been fixed). Elsewhere than in the United States the Le Chatelier test is widely used, wherein the expansion of neat cement moulded in a small brass cylinder, after immersion in boiling water for three hours, is measured. The chief causes of unsoundness of cement are assumed to be free, dead-burned, uncombined lime and magnesia which remain unhydrated for a long time at ordinary temperatures.

Time of setting as determined by a Vicat needle must not be less than 45 min., or by a Gillmore needle 60 min. In this test the penetration of a weighted needle during the setting period is the criterion. The final set must be attained within ten hours.

The strengths of mortar specimens made of 1 part of cement and 3 parts of standard sand, according to the A.S.T.M. specifications for standard portland cement, must equal or exceed the following:

Age in days	Storage of specimen	Tensile strength Lb. per sq in.
7	1 day in moist air 6 days in water	275
28	1 day in moist air 27 days in water	350

For high early strength portland cement the following:

Age in days	Storage of specimen	Option No 1 Tensile strength P.S.I.	Option No. 2 Compressive strength P.S.I.
1	1 day in moist air	275	1,300
3	1 day in moist air 2 days in water	375	3,000

This was not considered necessary in the A.S.T.M. specifications for several years prior to 1940. In that year new specifications were adopted covering five types of portland cement, with requirements for fineness varying from minimums 1,600 sq.cm. per gram to 1,800. While the A.S.T.M. specifications do not designate these five varieties of portland cement by other names than type I, type II, etc., they conform closely to the five varieties defined by the U.S. bureau of reclamation in the table on page 110A, except that the order is different: Type I is so-called standard cement; type II, modified; type III, high early strength; type IV, low heat of hydration; type V, sulphate resisting. Modern cements are ground to sizes measured in microns rather than openings of the finest wire sieves, yet specifications requiring from 92% to 98% to pass a 200-mesh sieve (200 meshes to the linear inch, or openings of 74 microns on a side) are common—in some instances to insure that a small percentage be retained on the sieve and the cement be not too finely ground. Many specifications define required fineness in terms of specific surface area per gram, as 1,700 sq.cm. (calculated on the assumption that the parti-

cles are spheres). This estimation is made by use of an instrument known as a turbidimeter, which determines the turbidity of a suspension of cement in some nonreactive liquid medium, such as kerosene, by measuring the intensity of light penetrating the suspension. Determination of the approximate percentages of the various sizes of particles is also made by use of an elutriator using either a liquid or air medium.

Composition.—The essential chemical components of portland cement are the oxides of calcium, silicon, aluminum and iron—CaO, SiO_2, Al_2O_3, Fe_2O_3. As a result of adding gypsum to control the setting time SO_3, sulphuric anhydride, is also present. Other constituents such as magnesium oxide (MgO) and compounds of sodium and potassium are usually present in small amounts. Chemical analyses are made in terms of these oxides, although they do not exist in unhydrated cement as simple oxides but are in complicated combinations brought about by partial melting, forming liquid and solid solutions and subsequent cooling to phase equilibrium, depending not only on the proportions of the various oxides but on the temperatures of the melt and of that of the freezing or crystallization. It is therefore possible to obtain cements with quite different characteristics from the same proportions of the essential oxides. The chemical analysis of a typical portland cement is given by F. M. Lea and C. H. Desch as follows:

Lime, CaO	64.10%
Silica, SiO_2	22.90%
Alumina, Al_2O_3	4.50%
Iron oxide, Fe_2O_3	3.11%
Magnesia, MgO	0.79%
Rutile, TiO_2	0.24%
Sodium oxide, Na_2O	0.54%
Potassium oxide, K_2O	0.64%
Sulphuric anhydride, SO_3	2.37%
Loss on ignition by difference	0.81%

From this analysis it is possible, by certain assumptions, to calculate the probable compound composition in the quaternary system $CaO.Al_2O_3.SiO_2.Fe_2O_3$ as

$4CaO.Al_2O_3.Fe_2O_3$	9.5%	$3CaO.SiO_2$	42.0%
$3CaO.Al_2O_3$	6.7%	$2CaO.SiO_2$	34.0%

The two latter, tricalcium silicate and dicalcium silicate, are the most essential and useful. Their actual identification can be made only by microscopic or X-ray analysis.

Uses of Portland Cement.—The demand for portland cement for use in structural work continues to grow, and, in addition to this, portland cement is being used for an increasing variety of purposes (*see* CONCRETE), which can only be briefly mentioned. Concrete, sometimes reinforced with iron or steel, is being used for all big structural buildings, engineering works, harbours, docks, ships, piers, bridges, piles, general building, artificial stone, roads (both foundation and surface), water towers, natatoria, lakes, etc., and the facility with which the concrete can be placed in any position and the fact that local stone and sand can frequently be used to the extent of 5 to 10 parts to 1 of cement are very important points with regard to cost of labour and carriage, as compared with that of stone. Concrete is also used for smaller articles such as telegraph poles, railway signal posts, sleepers, fencing posts, monuments, tombstones, coffins, troughs of various kinds, tiles, bricks, pipes (spun and moulded), paving blocks, manhole covers, etc. Very considerable developments have also been made in the use of cement for ornamental work, including not only that required for buildings, but sculptural work of all description, both large and small; and by the introduction of various aggregates, excellent substitutes for different ornamental stones have been made, frequently having improved weathering properties. Portland cement is particularly useful where there is much repetition of ornamental work; *e.g.*, for the capitals of pillars, tracery, etc. In the case of stone each piece must be carved separately, whereas a few moulds will be sufficient for a large number of blocks of cement concrete.

Theory of Setting.—The reason for the setting and hardening of portland cement continues to afford abundance of scope for fascinating research work. The comparatively simple ternary system of the lime-silica-alumina group becomes very complicated through thermal changes which are very dependent on the temperature from which the clinker is cooled, and also on the rate of cooling. Moreover, the balance of solution of the various constituents is modified by the different impurities included in the clinker. In addition to this there is some evidence that the constituents of the cement itself tend to acquire a more stable condition on storage. The investigation of the setting and hardening of cement is still more difficult. The simple hydration theory of earlier days has, on closer investigation, resolved itself into an extremely complex system which includes an infinite number of partially hydrated compounds, together with the formation of new compounds. A large amount of research work has been carried out on fairly pure preparations of the various silicates and aluminates of lime with good results; but their value is restricted because very different and complex action takes place when they are mixed, which accounts for the widely differing results obtained by the most recent research. Some of the above compounds have helped in the identification of some of the constituents in set cement (*e.g.*, small hexagonal plate crystals of tricalcium aluminate, fine needle crystals of monocalcium silicate, colloidal masses of monocalcium silicate, large hexagonal crystals of calcium hydrate, etc.), and apparently the colloidal monocalcium silicate plays a large part in the hardening of the cement. Thus the two schools of theorists—the crystalline and colloidal—are being brought together. Although no final conclusions have been reached, the general results of these investigations have been valuable and have resulted in a very marked improvement in the quality of portland cement.

OTHER CEMENTS

Rapid-Hardening Cements.—The demand for speed in construction during recent years has resulted in the development of the aluminous type cements—those high in alumina. They differ from portland cements in the proportions of lime, silica, and alumina; the lime varying from 36.5% to 44%, the silica from 4.5% to 9.5%, and the alumina from 36.5% to 44%. Since impure bauxite is the source of the alumina there is usually a considerable percentage of iron present as Fe_2O_3, sometimes as much as 14%. Such cements develop tensile strengths in 1:3 mortar briquettes of more than 500 p.s.i. in one day, or as much as ordinary portland cement briquettes in 28 days. Concrete made with these cements is more resistant to the action of sea water and sulphate waters than that made with ordinary portland cement It also has refractory properties. It hydrates with the release of much more heat than portland cement, and for that reason is not suitable for mass concrete under ordinary conditions. It has been used quite successfully for winter concrete construction because its heat of hydration delays freezing and because it hardens so rapidly. Aluminous cements, like portland cement, are made in rotary kilns and also in electric furnaces. The melting or slagging in the formation of the clinker is carried farther than in the manufacture of portland cement, and it costs much more to produce.

The success of aluminous cements led to development of portland cements that also harden rapidly—known in the United States, where most of this development has taken place, as high early strength portland cements. With these it is possible to obtain one-day strengths comparable to those of aluminous cements. They differ from standard portland cement in having a higher tricalcium silicate ($3CaO.SiO_2$) content and are usually more finely ground. They also develop more heat of hydration than desirable for mass concrete.

Low-Heat Cements.—To avoid so far as possible cracks in great masses of concrete, which are caused by temperature changes during the hardening and curing period, a low heat of hydration portland cement has been developed. It was first used on a large scale for the construction of the Hoover dam on the Colorado river by the U.S. bureau of reclamation. These low-heat cements are characterized by high percentages of dicalcium silicate ($2Ca.SiO_2$) and tetracalcium alumino ferrite ($4CaO.Al_2O_3.Fe_2O_3$) and low percentages of tricalcium silicate ($3Ca.SiO_2$) and tricalcium aluminate ($3CaO.Al_2O_3$). While the actual criterion is low heat of hydration, which can be accurately determined by a special type of calorimeter, specifications used by the United States govern-

ment aim to secure the desired quality through chemical limitations, which require a high percentage of silica, low lime and both alumina and iron oxide low or present in such prescribed ratios that the calculated $3CaO.Al_2O_3$ shall be low (6% to 8%).

For similar massive concrete structures a modified portland cement has been developed and is extensively used by the United States government. The compound composition of modified cement is characterized by low tricalcium aluminate ($3CaO.Al_2O_3$) and high tetracalcium alumino ferrite ($4CaO.Al_2O_3.Fe_2O_3$) with the percentages of tricalcium silicate ($3Ca.SiO_2$) and dicalcium silicate ($2CaO.SiO_2$) approximately the same as in standard portland cement. The hydration of tricalcium aluminate is the cause of most of the undesired heat and the object is to combine the alumina in the less active tetracalcium alumino ferrite, although it is known that this component has little value as a cementing material.

Sulphate-Resisting Cements.—For concrete structures in regions exposed to alkali soils and waters it has been found that ordinary portland cements often proved unsatisfactory. Two types of cement have been developed to provide more resistant concrete. A portland cement designed for this purpose is unusually high in tricalcium silicate ($3CaO.SiO_2$) and dicalcium silicate ($2CaO.SiO_2$) and unusually low in tricalcium aluminate ($3CaO.Al_2O_3$) and tetracalcium alumino ferrite ($4CaO.Al_2O_3.Fe_2O_3$), the sum of these two being less than for any other type of cement. It is difficult to manufacture because it is low in fluxing agents (alumina and iron). The second type of cement designed for sulphate resistance is portland-pozzolana. In the manufacture of these, portland cement and a pozzolana, natural or artificial, are intimately mixed or ground together. A pozzolana is defined as a siliceous material which will react with lime in the presence of water at ordinary temperatures. Obviously, there are various degrees of pozzolanic activity. This type of cement has been much more extensively made and used in Europe than in the United States.

A comparison of the compound compositions of these cements (omitting the portland-pozzolana) is given in the following table (from the *Concrete Manual*, U.S. bureau of reclamation), in which tricalcium silicate ($3CaO.SiO_2$) is designated, as is common in cement literature, as C_3S; dicalcium silicate ($2CaO.SiO_2$) as C_2S; tricalcium aluminate ($3CaO.Al_2O_3$) as C_3A; tetracalcium alumino ferrite ($4CaO.Al_2O_3.Fe_2O_3$) as C_4AF:

Type of Cement		Compound Composition (Percentages)							Ignition loss
		C_3S	C_2S	C_3A	C_4AF	$CaSO_4$	Free CaO	MgO	
High early strength portland	Max.	70	38	17	10	4.6	4.2	4.8	2.7
	Min.	34	0	7	6	2.2	0.1	1.0	1.1
	Average	50	15	12	8	3.9	1.3	2.6	1.9
Standard portland	Max.	54	43	14	10	3.3	1.5	3.8	2.3
	Min	29	22	9	6	2.2	0.0	0.7	0.6
	Average	43	31	12	8	2.8	0.8	2.4	1.2
Modified portland	Max.	50	46	9	18	3.3	1.8	4.4	2.0
	Min.	29	22	3	10	1.9	0.1	1.5	0.5
	Average	43	30	6	13	2.9	0.6	3.0	1.0
Sulphate-resisting portland	Max.	55	49	6	9	3.1	0.6	2.3	1.2
	Min.	35	27	4	5	2.7	0.1	0.7	0.8
	Average	45	40	5	7	2.9	0.4	1.6	1.0
Low-heat portland	Max.	33	61	8	18	4.0	0.9	4.1	1.0
	Min.	10	41	3	6	2.5	0.0	1.0	0.0
	Average	21	51	6	14	3.2	0.5	2.7	1.1

White Cements.—White portland cements are of approximately the same composition as standard portland cements except that the iron oxide content is very low, and special care must be taken in processing to avoid contamination which would discolour the product. Cryolite and fluorspar are frequently used as fluxing agents. Suitable raw materials are quite scarce.

Portland Blast-Furnace Cement.—A type of cement made largely in Germany (Eisenportland) is a mixture of portland cement clinker and granulated slag ground to the required fineness. It is a pozzolana cement, as understood in the United States. A similar cement, although not a true portland, is made of a mixture of hydrated lime and granulated slag.

Masonry Cements.—A great variety of cements for brick and stone masonry have been developed to overcome the harsh-working handicap of ordinary portland cement mortars. They consist of mixtures of portland cement with one or more of the following: hydrated lime, granulated slag, pulverized limestone, colloidal clay, diatomaceous earth or other finely divided form of

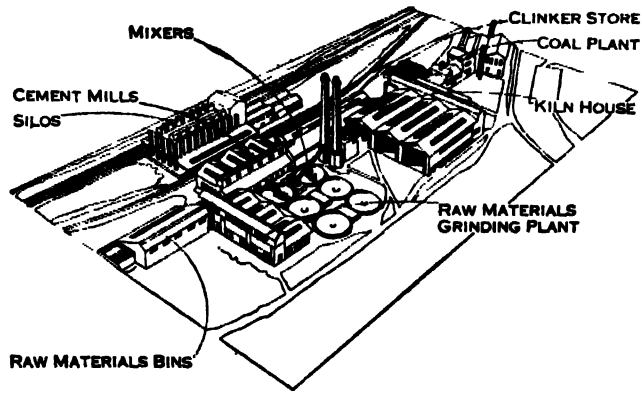

FIG. 2.—DIAGRAM OF LAYOUT OF A WET PROCESS CEMENT PLANT
The raw materials are ground to a slurry which is then pumped into the mixers and from there to the rotating kiln. In passing through the kiln it becomes dried, then decarbonated and finally, in the burning zone, clinkered. The white hot clinker passes through coolers, heating the air for the kilns, and when cool, is ground in tube mills

silica, calcium stearate, paraffin, etc. The various ingredients and their proportions are often kept secret or are patented and they are frequently described as patent mortar cements.

Natural Cements.—In the United States the rapid development of the portland cement industry was caused in large measure by discovery of large deposits of natural cement rock. The Lehigh valley is a notable example. These argillaceous limestones contain the necessary minerals for portland cement manufacture in approximately the correct proportions. Later refinements in manufacture have made it necessary in some cases to add to the mix small quantities of higher grade limestones or to concentrate the calcium carbonate in the original stone by flotation. For many years cements made from these limestones in vertical shaft kilns, like lime, were used, and are still used to some extent, as natural cements, without attempting to simulate portland cement.

Lime Cements.—These include various grades, from the pure "fat" white lime through the gray limes to the hydraulic limes which have already been referred to under portland cement. White lime consists of oxide of calcium, or, in its slaked form, hydrate of calcium. It is prepared by calcining calcium carbonate (chalk or limestone) until all the carbonic anhydride has been driven off and only the oxide is left. This oxide (quicklime) has great affinity for water, with which it combines readily, forming calcium hydrate, or slaked lime. This action is exothermic (*i.e.*, gives out heat) and is very vigorous unless it is properly controlled. The dry slaked lime occupies two or three times the volume of the original quicklime, according to the method by which it is slaked. Gray lime is an impure form of white lime, and according to the quantity and nature of the impurities, its properties vary between white lime and hydraulic lime. The latter differs from white or gray lime in that, owing to the amount of argillaceous material contained in it, the lime slakes comparatively slowly, and when used for making mortar is capable of hardening under water.

Lime, probably on account of its long history, is frequently made in the simplest form of kiln, the bottle kiln, which is extremely extravagant with both coal and labour, particularly if white lime is being produced as this must be kept free from the ash of the fuel. Various other kilns, such as those described under portland cement, are also used, but the rotary kiln is in very general use for limestone burning, fired either with producer gas or with pulverized coal, and lime is obtained from this kiln with great economy of labour and fuel provided the raw material is sufficiently pure. Another great advantage of this kiln is that it will take "smalls": *i.e.*, material which is so small that it would choke a stationary kiln, and therefore has to be rejected. On the other hand a rotary kiln is not suitable for burning large lumps

of chalk or limestone, and as there is a certain demand for large lumps of lime (probably because of the uncertain quality of the fine stuff in the earlier days), it is still necessary to use fixed kilns if this demand is to be met.

Lime, before it is used for mortar, must be slaked, and this was formerly done at the place where it was to be used. On account of the irregular way in which this was sometimes carried out, portions of the less pure lime used to slake and expand after the mortar had been used and cause the work to blow. To overcome this trouble, architects and others frequently specify that the mortar should be made up two or three months before use. This method of overcoming the difficulty was at the expense of the strength of the finished mortar, for the lime was carbonating and deteriorating during this period. The modern method is to slake the lime mechanically at the lime works and remove the slaked lime from the unslaked by air separation. The slaked lime is then stored in bulk for 10 to 14 days, after which it is ready for use, yielding a lime which is free from any risk of blowing, and at the same time retaining its hardening properties unimpaired.

Mortar made from white lime and the purer forms of gray lime works very easily under the trowel, and if necessary, can be floated off to a very smooth surface for facing walls, etc., and on account of this property the white lime is frequently spoken of as "fat" lime because it is supposed to suggest the smoothness of butter. Experiments have been made to improve the lime for mortar purposes, etc., by the addition of various substances to the water used for slaking, or to the slaked lime.

The setting of white lime and gray lime is largely due to drying out, and to a small extent calcium hydrate recrystallization. The hardening appears to be almost entirely due to the lime combining with the carbon dioxide in the air and forming calcium carbonate, although this is sometimes assisted by a slight pozzolanic effect of the silica in the sand or other material used with the lime. In hydraulic lime the setting and hardening properties are due to a combination of the above with that of those constituents which are similar to portland cement. For most purposes portland cement has taken the place of hydraulic lime; but there are still certain conditions where the latter is preferable to the former, particularly for embedding large steel sections, where the hardening effect should not take place until the steel has finally settled into position.

Selenitic Cement.—The addition of 5% to 10% of plaster of Paris to lime increases the hardening properties of the latter by 50% to 100%, and this mixture is sometimes known as selenitic cement.

Pozzolanic Cement.—Lime, in the presence of water, readily combines with silica in the active state and forms a calcium silicate similar to that in portland cement. Various natural and artificial materials, such as pozzolana, trass, kieselguhr, pumice, tufa, santorin earth, granulated slag, etc., contain active silica, and where the cost is low they make a useful addition to lime mortar. To obtain the best effect the granulated slag, or other material, should be ground with the lime until both materials are in a fine state of division and intimately mixed.

When properly made, pozzolanic cements will attain a strength approaching that of portland cement; but frequently the material is simply mixed with the lime, and the bulk of the pozzolanic material acts as an aggregate instead of an active constituent of the cement.

Calcium Sulphate Cements.—This class includes all those cements which primarily depend on the hydration of calcium sulphate for their setting and hardening properties and includes plaster of Paris, Keene's cement, Parian cement, etc. The raw material is gypsum (*q.v.*), which may be almost chemically pure, in which case it is suitable for Keene's cement and other special brands, or may contain a small quantity of foreign matter, when it is suitable for ordinary plaster of Paris. The mode of preparation is to calcine the gypsum at a comparatively low temperature, viz., about 205° C. for plaster of Paris, at which temperature the gypsum loses three-fourths of its combined water, and at about 500° C. for the Keene's cement class, when the whole of the combined water is driven off. At a higher temperature the gypsum becomes "dead burned" and will then only hydrate very slowly, or in some cases not at all. The gypsum for plaster of Paris is usually calcined either in ovens or in kettles, and for Keene's cement in kilns, where the ash of the fuel can be kept away from the finished product. These methods are inferior in economy to the rotary kiln, and this type of kiln will probably be the method of the future as, if fired with producer gas, the product is not contaminated with ash. The setting of plaster of Paris depends on the fact that when $2CaSO_4.H_2O$ is treated with water it dissolves, forming a super-saturated solution of $CaSO_4.2H_2O$. The excess held temporarily in solution is then deposited in crystals of $CaSO_4.2H_2O$. In the light of this knowledge the mode of setting of plaster of Paris becomes clear. The plaster is mixed with a quantity of water sufficient to make it into a smooth paste; this quantity of water is quite insufficient to dissolve the whole of it, but it dissolves a small part and gives a super-saturated solution of $CaSO_4.2H_2O$. In a few minutes the surplus hydrated calcium sulphate is deposited from the solution and the water is capable again of dissolving $2CaSO_4.H_2O$, which in turn is fully hydrated and deposited as $CaSO_4.2H_2O$. The process goes on until a relatively small quantity of water has by instalments dissolved and hydrated the $2CaSO_4.H_2O$, and has deposited $CaSO_4.H_2O$ in felted crystals forming a solid mass well cemented together. The setting is rapid, occupying only a few minutes, and is accompanied by a considerable expansion of the mass. There is reason to suppose that the change described takes place in two stages, the gypsum first forming orthorhombic crystals and then crystallizing in the monosymmetric system. Gypsum thus crystallized in its normal monosymmetric form is more stable under ordinary conditions than the orthorhombic form. Correlatively, in its process of dehydration to form plaster of Paris, monosymmetric gypsum is converted into the orthorhombic form before it begins to be dehydrated.

The essential difference between the setting of Keene's cement and that of plaster of Paris is that the former takes place much more slowly, occupying hours instead of minutes, and the considerable heating and expansion which characterize the setting of plaster of Paris are much less marked.

It is the practice in Great Britain to burn pure gypsum at a low temperature so as to convert it into the hydrate $2CaSO_4.H_2O$, to soak the lumps in a solution of alum or of aluminium sulphate and to recalcine them at about 500° C. Instead of alum various other salts—borax, cream of tartar, potassium carbonate, etc.—may be used. On grinding the recalcined lumps they give Keene's cement, Parian cement, Keating's cement, etc. The quantity of these materials is so small that analyses of Keene's cement show it to be almost pure anhydrous calcium sulphate and make it difficult to explain what, if any, influence these minute amounts of alum and the like can exert on the setting of the cement.

These cements form excellent decorative plasters on account of their clean white colour and the sharpness of the castings made from them, this latter quality being due to their expansion when setting. Keene's cement is especially adaptable for surfaces where a hard polished finish is required. All cements having calcium sulphate as their base are suitable only for indoor work because of their solubility in water.

Oxychloride Cements.—In 1853 Sorel discovered that zinc chloride solution, when mixed with zinc oxide, formed a very hard cement, and later he found that magnesium chloride, magnesia and various other metallic oxides and chlorides did the same, an oxychloride being formed in each case. Of these the most important is the magnesia oxychloride, commonly known as Sorel cement, and on account of its great strength and unusual binding properties it is used for such widely different purposes as uniting carborundum for grindstones, where great strength and rigidity are required, and binding wood sawdust together to form monolithic floors which have a certain amount of spring in them. It is also used for making artificial marble and other ornamental stone, and if cast on glass which has been waxed to prevent adhesion the material, on removal of the glass, will have a highly glazed surface.

The magnesia, which should be freshly calcined and ground,

mixed with several times its volume of carborundum, wood sawdust, sand or other material, and is then moistened with a solution of magnesium chloride having a density of 25°–30° Baume, and thoroughly mixed so that each grain of material is covered with the magnesia oxychloride. The plastic mass is then put into moulds, or placed in position and floated off.

The speed of setting and hardening is dependent on the freshness of the magnesia and the strength of the solution of the magnesium chloride, and when the right strength has been found for any particular batch of materials this should be rigidly adhered to for the work.

Adhesive Cements.—Mixtures of animal, mineral and vegetable substances are employed in great variety in the arts for making joints, mending broken china, etc. A strong cement for alabaster and marble, which sets in a day, may be prepared by mixing 12 parts of portland cement, 8 of fine sand and 1 of infusorial earth, and making them into a thick paste with silicate of soda; the object to be cemented need not be heated. Casein, with some solvent, usually an alkali, forms the basis of many waterproof cements and cold-water glues. For stone, marble and earthenware a strong cement, insoluble in water, can be made as follows: skimmed-milk cheese is boiled in water till of a gluey consistency, washed, kneaded well in cold water, and incorporated with quicklime; the composition is warmed for use. A similar cement is a mixture of dried fresh curd with one-tenth of its weight of quicklime and a little camphor; it is made into a paste with water when employed. A cement for Derbyshire spar and china, etc., is composed of 7 parts of rosin and 1 of wax, with a little plaster of Paris; a small quantity only should be applied to the surfaces to be united, for, as a general rule, the thinner the stratum of cement the more powerful its action. Quicklime mixed with white of egg, hardened Canada balsam, and thick copal or mastic varnish are also used for cementing broken china, which should be warmed before their application. For small articles, shellac dissolved in spirits of wine is a very convenient cement.

Cements such as marine glue are solutions of shellac, India rubber, or asphaltum in benzine or naphtha. For use with wood which is exposed to moisture, as in the case of wooden cisterns, a mixture may be made of 4 parts of linseed oil, boiled with litharge, and 8 parts of melted glue; other strong cements for the same purpose are prepared by softening gelatine in cold water and dissolving it by heat in linseed oil, or by mixing glue with one-fourth of its weight of turpentine, or with a little bichromate of potash. Mahogany cement, for filling up cracks in wood, consists of 4 parts of beeswax, 1 of Indian red, and yellow ochre to give colour. Cutler's cement, used for fixing knife blades in their hafts, is made of equal parts of brick dust and rosin, melted, or of 4 parts of rosin with 1 each of beeswax and brick dust. For covering bottle corks a mixture of pitch, brick dust and rosin is employed. A cheap cement, sometimes used to fix iron rails in stonework, is melted brimstone, or brimstone and brick dust. For pipe-joints a mixture of iron turnings, sulphur and sal ammoniac, moistened with water, is employed. Japanese cement, for uniting surfaces of paper, is made by mixing rice flour with water and boiling it. Jewellers' or Armenian cement consists of isinglass with mastic and gum ammoniac dissolved in spirit. Gold and silver chasers keep their work firm by means of a cement of pitch and rosin, a little tallow and brick dust to thicken. Temporary cement, for lathe work, such as the polishing and grinding of jewellery and optical glasses, is compounded thus: rosin, 4 oz., whitening previously made red hot, 4 oz., wax, ¼ oz.

(W. H. Wo.; N. C. R.)

CEMENTATION, a metallurgical term which describes processes by which one substance is, by exposure to great heat in a furnace, caused to interpenetrate and change the character of another. Although a high temperature is employed, the process is not one of melting materials together, but of combining them through contact at a temperature which is below their melting points. Thus, in the manufacture of blister steel by cementation, a rod of iron becomes steel because exposed at a temperature of about 1,000° C. to carbon which penetrates its substance. (*See* BLISTER STEEL; IRON AND STEEL.)

CEMENT ROCK. A cement rock is an argillaceous (clayey) limestone whose composition is such that it may be used for the manufacture of cement without the addition of other earth materials or with the addition of only relatively small amounts of such materials. Some cement rocks contain the mineral quartz as silt or sand particles along with their argillaceous component. The principal carbonate in cement rocks employed for portland cement manufacture is calcium carbonate; magnesium carbonate must be low, in accordance with the usual specifications for Portland cement raw materials. High-calcium limestone, clay or shale may be blended with the cement rock to modify its composition. Rock used for making natural cement, sometimes referred to as a natural-cement rock, is of similar character to that mentioned above but the allowable amount of magnesium carbonate is flexible. Both dolomitic and calcitic argillaceous limestones have been used as natural-cement rocks.

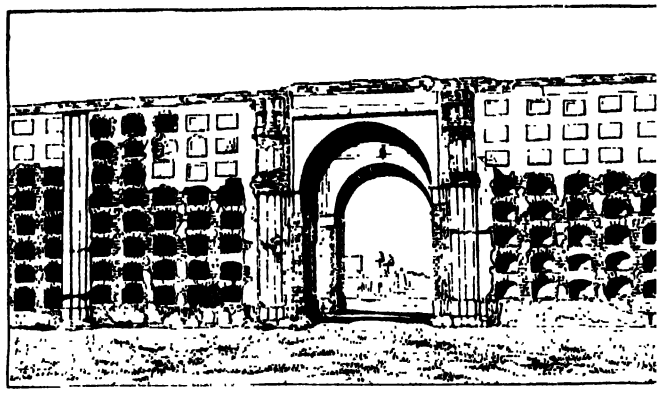
CEMETERY, literally a sleeping place, the name applied by the early Christians to the places set apart for the burial of their dead. These were generally extramural and unconnected with churches, the practice of interment in churches or churchyards being unknown in the first centuries of the Christian era. The term cemetery has, therefore, been appropriately applied in modern times to the burial grounds, generally extramural, which have been substituted for the overcrowded churchyards of populous parishes both urban and rural (*see* BURIAL).

From 1840 to 1855 attention was repeatedly called to the insanitary condition of the London churchyards by the press and by parliamentary committees, the first of which reported in 1843. The vaults under the pavements of the churches and the small spaces of open ground surrounding them were crammed with coffins. In many of the buildings the air was so tainted with the products of corruption as to be a direct and palpable source of disease and death to those who frequented them.

In the churchyards coffins were placed tier above tier in the graves until they were within a few feet (or sometimes even a few inches) of the surface, and the level of the ground was often raised to that of the lower windows of the church.



To make room for fresh interments the sextons had recourse to the surreptitious removal of bones and partially decayed remains, and in some cases the contents of the graves were systematically transferred to pits adjacent to the site, the grave diggers appropriating the coffin-plates, handles and nails to be sold as waste metal.

The neighbourhood of the churchyards was always unhealthy, the air being vitiated by the gaseous emanations from the graves, and the water, wherever it was obtained from wells, containing organic matter, the source of which could not be mistaken.

In all the large towns the evil prevailed in a greater or less degree. In London, however, because of the immense population and the consequent mortality, it forced itself more readily upon public attention; and after more than one partial measure of relief had been passed the churchyards were, with a few exceptions, finally closed by the act of 1855.

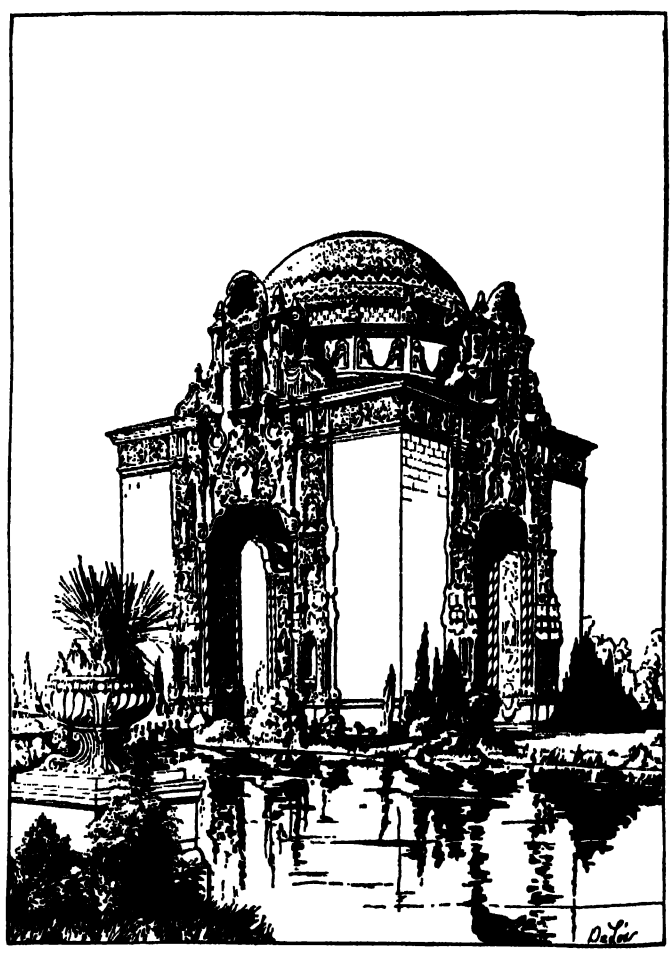
The cemeteries, which occupy a large extent of ground north,

south, east and west became henceforth the burial-places of the metropolis. Several London cemeteries had been established by private enterprise before the passing of the Burial Act of 1855 (Kensal Green cemetery dates from 1832), but that enactment forms the epoch from which the general development of cemeteries in Great Britain and Ireland began. Burial within the limits of cities and towns is now almost everywhere abolished,

BY COURTESY

COMMUNAL VAULTS, GUATEMALA

In these concrete walls with rows of receptacles for coffins, the remains of the dead are left intact so long as rent is paid. On failure to pay the rent, the bones are removed and buried in a common heap, and the "pigeon hole" is rented again



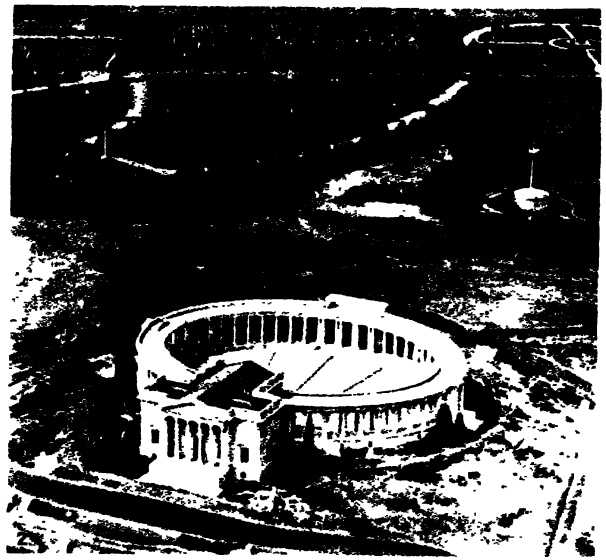
and where it is still in use it is surrounded by such safeguards as make it practically innocuous. The increasing practice of cremation (*q.v.*) has assisted in the movement for disposing of the dead in more sanitary conditions; and the practice of burying the dead in more open coffins, and abandoning the old system of family graves, has had considerable effect.

In England a cemetery is either the property of a private company incorporated by Act of Parliament or of a local authority and is subject to the Cemeteries Clauses Act 1847, the Public Health Act, 1875 and the Public Health (Interments) Act, 1879. By S. 33 of the Burial Act, 1852, a burial board under such conditions as it thinks proper may sell the exclusive right of burial, either in perpetuity, or for a limited period, in grave spaces; the right of constructing any vault or place of burial with the exclusive right of burial therein in perpetuity, or for a limited period; and also the right of erecting and placing any monument, gravestone, tablet or monumental inscription. By S. 38 the general management, regulation and control of a burial ground is vested in the burial board. Regulations are made by the Minister of Health and Rules may be made by the board. By S. 44 of the Cemeteries Clauses Act 1847 the grant of the right of burial, whether in perpetuity or for a limited time, becomes the personal estate of the grantee. Under such a grant there is implied the right to visit the grave, and to plant shrubs and plants and to keep the surface in order, and if there is a monument, head or curb stones to keep them in repair (see *Ashby* v. *Harris* | 1868] L.R. 3 C.P. 523). This case was discussed, but not overruled in *McGough* v. *Lancaster Burial Board* (1888) 21 Q.B. D. 323 where, in consequence of a rule of the board, made prior to the grant, prohibiting the placing of glass shades on graves, it was held that the grant of burial in a grave space to the plaintiff did not include a right to place a glass shade on his grave. Although a burial board cannot sell the freehold of a grave space, the property in a vault, tomb, monument, headstone, curb or any other erection remains in the person who erected them. See *Spooner* v. *Brewster* (1825) 3 Bing. 136 and *Sims* v. *The London Necropolis Co.* (1885) 1 T.L.R. 584; but *see* also *Hoskyns Abrahall* v. *Paignton U.D.C.* (1928) 2 Ch. (*See* J. B. Little, *Law of Burial*, 1902.)

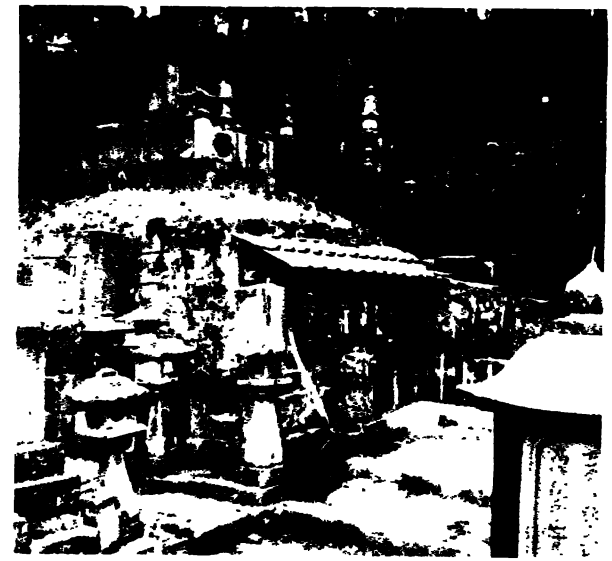
UNITED STATES

In the United States cemeteries were the final outgrowth of individual burial places on the farms or near the homes of the earliest settlers. Later the burial place was connected with the church, which custom is not entirely obsolete. Prominent men were buried beneath the church building for a long time during the 17th and 18th centuries, but the crowded conditions together with the fact that the practice was recognized as unsanitary caused it to be abandoned. In villages and small towns the church "graveyards" grew into disrepute many years ago because of the neglect they were subjected to. There was no provision for care of such burial places, except the slight attention a sexton would give, and disorder resulted. Detached cemeteries have been in use in the United States since 1831 when Mt. Auburn was established in Boston. Philadelphia soon after set up some notable large burial places and Greenwood in New York had its beginning in 1840. From 1860 churchyard burials have gradually been discontinued until to-day they are but exceptions to the rule of beautiful community cemeteries. From single burial plots on private property, to church graveyards, to cemeteries and now to "memorial parks" has been a notable transition.

During the days when cemeteries were maintained by and in connection with the church, members and their families were entitled to a burial site. No expense was attached to the burial except the cost of opening the grave. No funds were available for upkeep which accounts for the deterioration of the property, and the ultimate abandoning of that type. In the cemeteries of to-day lots are sold by the city or village, if owned by such a body, or by the association, which has charge. A definite fee is charged for perpetual care and a charge is made for opening the grave and



BY COURTESY OF THE PORTLAND CEMENT ASSOCIATION



ENTRANCE TO VALHALLA MEMORIAL PARK IN BURBANK, CALIFORNIA

other duties performed by the sexton or superintendent. Generally speaking cemeteries are supposed to be maintained with no idea of profit, and that holds good in a great majority of places.

Some churches have their own cemeteries, though not in connection with the church, notably the Catholic church. The Jews have many beautiful burial sites, and now and then one comes across a cemetery maintained by one or another of the Protestant societies. Throughout the country there are many beautiful cemeteries maintained by the Masonic or other fraternities for their own members and members of their families. There are many

CEMETERIES IN THE EAST AND WEST

1. Palestine, Jewish cemetery in the Garden of Gethsemane, valley of Jehoshaphat, showing tombs of S. James, Absalom and Zachariah in the foreground
2. Amphitheatre at Arlington National Cemetery, Washington, D.C., showing soldiers' graves in the background
3. Cemetery in Matsue, Japan
4. Indian graves in southern Chile
5. Talma's tomb in the Père Lachaise cemetery, Paris
6. Graveyard of the Ages, in Canton, southern China

State and national cemeteries in the United States provided by statute, given over to the burial of departed army and navy men, and men connected with State institutions, usually attached to soldiers' homes or army posts.

CENACLE, the term applied to the eating-room of a Roman house in which the supper (*cena*) or latest meal was taken. It was sometimes placed in an upper storey. The Last Supper in the New Testament was taken in the cenacle, in the "large upper room" cited in St. Mark (xiv. 15) and St. Luke (xxii. 12).

CENCI, BEATRICE (chĕn'chē) (1577–1599), a Roman woman, famous for her tragic history, was born on Feb. 6, 1577, in the Cenci palace in Rome. She was the daughter, by his first wife, of Francesco Cenci (1549–1598), a vicious man of great wealth. He was tried in 1594 for sodomy, but was released on payment of a fine of 100,000 scudi. Cenci had 12 children by his first wife; his second wife, Lucrezia Petroni, a widow with three daughters, brought him no children. He was embroiled with his sons and after the trial he decided to remove his wife Lucrezia, with Beatrice, to La Petrella, a lonely castle on the road to Naples which he obtained from Marzio Colonna. There in 1595 he shut up his wife and daughter in the upper rooms of the castle, and there he visited them from time to time treating them, especially Beatrice, with great brutality. There is no evidence for the charge of attempted incest with his daughter, but the details of life at La Petrella, as given in the subsequent trial, were revolting, and might well have given colour to the accusation. Beatrice seems to have found refuge in a liaison with the keeper of the castle, Olimpio Calvetti. At intervals the two younger Cenci children, Bernardo and Paolo, visited La Petrella. Olimpio was expelled by Colonna from the castle at the demand of Francesco Cenci, who does not, however, seem to have known of his relations with Beatrice. At length, Beatrice, with her stepmother and with her brother Giacomo and Bernardo, decided to secure the murder of their father. He was killed in his bed (Sept. 9, 1598) by Olimpio and a hired assassin named Marzio.

Information having been communicated to Rome, the whole of the Cenci family were arrested early in 1599. Lucrezia, Giacomo and Bernardo confessed the crime; and Beatrice, who at first denied everything, even under torture, also ended by confessing. Great efforts were made to obtain mercy for the accused, but the pope (Clement VIII.) refused to grant a pardon; on Sept. 11, 1599, Beatrice and Lucrezia were beheaded, and Giacomo, after having been tortured with red-hot pincers, was killed with a mace, drawn and quartered. Bernardo's penalty, on account of his youth, was commuted to perpetual imprisonment, and after a year's confinement he was pardoned. The property of the family was confiscated. There is a study by Guido Reni or Guercino in the Palazzo Barberini said to represent Beatrice, but it is unlikely that Reni saw her.

The history of the Cenci family has been the subject of poems, dramas and novels. Shelley found in it material for his great tragedy. The most famous of the novels is F. D. Guerrazzi's *Beatrice Cenci* (Milan, 1872). The first attempt to deal with the subject on documentary evidence is A. Bertolotti's *Francesco Cenci e la sua famiglia* (2nd ed., Florence, 1879), containing a number of interesting documents which place the events in their true light; *cf.* Labruzzi's article in the *Nuova Antologia,* 1879, vol xiv., and another in the *Edinburgh Review,* Jan. 1879. *See* also C. Ricci, *Beatrice Cenci,* 2 vols. (1923), where new documents and new information are to be found.

CENOBITES, monks who lived together in a convent or community under a rule and a superior—in contrast to hermits or anchorets who live in isolation (from Gr. *κοινός, common,* and *βίος, life*). *See* MONASTICISM.

CENOMANI (Kĕn-ō-mah'nē), a branch of the Aulerci in Gallia Celtica, whose territory corresponded generally to Maine (department of Sarthe). Their chief town was Vindinum, afterwards Civitas Cenomanorum (whence Le Mans). They assisted Vercingetorix in the great rising (52 B.C.) with a force of 5,000 men. Under Augustus they formed a *civitas stipendiaria* (tributary community) of Gallia Lugdunensis. About 400 B.C., under the leadership of Elitovius (Livy v. 35), a large number of the Cenomani crossed into Italy, drove the Etruscans southwards, and occupied their territory. The limits of their territory are not clearly defined, but were probably the Adige on the east, the Addua on the west and the Padus (Po) on the south. Their chief towns were Brixia (Brescia) and Verona. They assisted the Romans in the Gallic war (225 B.C.), when the Boii and Insubres took up arms against Rome, and during the war against Hannibal. They joined in the revolt of the Gauls under Hamilcar (200), but after they had been defeated by the consul Gaius Cornelius (197) they finally submitted. In 49 B.C., with the rest of Gallia Transpadana, they acquired the rights of citizenship.

(1876–93); Arbois de Jubainville, *Les Premiers Habitants de l'Europe* (1889–94); article and authorities in *La Grande Encyclopédie;* C. Hülsen in Pauly-Wissowa's *Realencyklopädie,* iii. pt. 2 (1899); full ancient authorities in A. Holder, *Alt-celtischer Sprachschatz,* i. (1896).

CENOTAPH, a monument or tablet to the memory of a person whose body is buried elsewhere (Gr. *κενός,* empty, *τάφος* tomb). The custom arose from the erection of monuments to those whose bodies could not be recovered, as in the case of drowning. The term is often used of the monuments raised in many places in memory of those who perished on the field in the World War, especially of the cenotaph in Whitehall, London, the scene of an annual memorial service on the anniversary of Armistice Day (*q.v.*).

CENSOR. I. *In ancient Rome,* the title of the two Roman officials who presided over the census (from Lat. *censere,* assess, estimate), the registration of individual citizens for the purpose of determining the duties which they owed to the community. This idea of "discretionary power" was never entirely lost; although it came to be intimately associated with the appreciation of morals. The censorship was the Roman manifestation of the state control of conduct.

The office was instituted in 443 B.C. to relieve the consuls of the duties of registration. The election always took place in the *Comitia Centuriata* (*see* COMITIA). The censorship, although lacking the imperium, was one of the higher magistracies, and was regarded as the crown of a political career. It was an irresponsible office; and the only limitations on its powers were the restriction of tenure to a year and a half, and the restraint imposed on each censor by the fact that no act of his was valid without the assent of his colleague.

The original functions of the censors were (1) the registration of citizens in the state-divisions, such as tribes and centuries; (2) the taxation of such citizens based on an estimate of their property; (3) the right of exclusion from public functions on moral grounds, known as the *regimen morum;* (4) the solemn act of purification (*lustrum*) which closed the census. Two other functions were subsequently added: (5) the selection of the senate (*lectio senatus, see* SENATE), and (6) certain financial duties such as the leasing of the contracts for tax-collecting and for the repair of public buildings. The census involved a detailed examination of the citizen body as represented by the heads of families. In connection with this review the censors published their edicts stating the moral rules they intended to enforce. Disqualification might be the result of offences in private relations or in public life. Certain kinds of employment (*e.g.,* acting) caused a stigma. *Infamia,* the general name for the penalties inflicted by the censors, varied in degree. A senator might lose his seat, a citizen his place in tribe and century, and so his vote. All disabilities inflicted by one pair of censors might be removed by their successors.

The censorship lasted as long as the republic; and it was only suspended, not abolished, during the principate. Although the *princeps* exercised censorial functions he was seldom censor. Yet the office itself was held by Claudius and Vespasian. Domitian assumed the title of life censor, but he was not followed.

BIBLIOGRAPHY.—Mommsen, *Römisches Staatsrecht* (1887), ii., 331, *et seq.;* A. H. J. Greenidge, *Roman Public Life* (1901); J. E. Sandys, *Companion to Latin Studies* (1921), with useful bibliography; W. E. Heitland, *Roman Republic* (1923).

II. In modern times the word "censor" is used generally for one who exercises supervision over the conduct of other persons. In the Universities of Oxford and Cambridge it is the title of the supervisor of those students who are not attached to a college, hall or hostel. In Oxford the censor is nominated by the vice-chancellor and the proctors, and holds office for five years; in Cambridge he is similarly appointed, and holds office for life. The censors of the Royal College of Physicians are the officials who grant licences.

Council of Censors, in American constitutional history, was the name given to a council provided by the constitution of Pennsylvania from 1776 to 1790, and by the constitution of Vermont from 1777 to 1870. Under both constitutions the council of censors was elected once in seven years, for the purpose of enquiring into the working of the governmental departments, the conduct of the state officers, and the working of the laws, and as to whether the constitution had been violated in any particular. The Vermont council of censors, limited in number to thirteen, had power, if they thought the constitution required amending in any particular, to call a convention for the purpose. A convention summoned by the council in 1870 amended the constitution by abolishing the censors.

For the censorship of the press, *see* PRESS LAWS; for the censorship of plays, LORD CHAMBERLAIN.

CENSORINUS, Roman grammarian and writer, flourished during the 3rd century A.D. He was the author of a lost work *De Accentibus* and of an extant treatise *De Die Natali,* written in 238, dedicated to his patron as a birthday gift and dealing with the natural history of man, the influence of the stars and genii, music, religious rites, astronomy and the doctrines of the Greek philosophers. The second part deals with chronological and mathematical questions and has been useful in determining the principal epochs of ancient history. The chief authorities used were Varro and Suetonius. Some scholars hold that the work is practically an adaptation of the lost *Pratum* of Suetonius. The fragments of a work *De Natali Institutione* are not by Censorinus.

The only good edition with commentary is still that of H. Lindenbrog (1614); the most recent critical editions are by O. Jahn (1845), F. Hultsch (1867), and J. Cholodniak (1889). There is an English translation of the *De Die Natali* (the first 11 chapters being omitted), with notes by W. Maude (1900).

CENSORSHIP. The censors in ancient Rome were the magistrates who drew up the register or census of the citizens and had the supervision of public morals (*see* CENSOR). Their functions in numbering the people have given us the English word "census"; and from their other activities the word "censorship" is derived.

Censorship in modern practice may be defined as action taken by the governing authority to examine letters and other communications and also the text of proposed books, stage plays and the like in order to prevent any publication which would be contrary to the public interest or inconvenient or displeasing to that governing authority.

Religious censorship has at times been attempted by several sections of Christianity. The Roman Catholic Church in particular worked out a complete system, *pari passu* with the secular censorships of national states: the *Index Librorum Prohibitorum* (*q.v.*) is published by papal authority as a catalogue of printed publications prohibited to Catholics on doctrinal or moral grounds. In modern times, however, it has been found impossible for the Congregation of the Index to keep pace with the output of the printing presses of the world; but there exist general rules which the particular prohibitions of the Index are intended only to supplement.

GREAT BRITAIN

Press Censorship.—There is a popular idea among Englishmen that the freedom of the press is one of their birthrights and that their ancestors always fought fiercely for it. The statute book, however, shows that this idea is not wholly correct.

From the time of the general introduction of printing, at the end of the 15th century, until the year 1695 there was a rigorous censorship of the press in England; and it was a criminal offense to publish any printed matter without first obtaining a licence to do so. Control was exercised by the Star Chamber and then by ordinances of the Long parliament, till in 1662 parliament passed the Licensing act (for the censorship of the press), which was renewed from time to time.

When the Licensing act was due for a further renewal in 1695, parliament had no intention of abolishing the control of the press. But the licensers (as the press censors were called) had been continually in dispute with the press; and evasions and complaints indicated that the administration of the censorship was defective. The house of commons appointed a select committee to report on ways and means to improve the censorship and to make it more effective. By what appears to have been an entirely fortuitous circumstance, the Licensing act was allowed to lapse before the select committee had reported; and it was never renewed. During World Wars I and II in the 20th century a measure of censorship was necessary for reasons of national security; but otherwise there was no censorship of the press in England after 1695. In Scotland the censorship of the press lingered on until the 18th century; and the Statute for the Licensing of the Press was not formally repealed until 1907. In Ireland also, before the union with Great Britain in 1800, there were Irish acts of parliament for the control of the press; but these were repealed.

In the United Kingdom the press is thus free to publish what it pleases, except that a few modern statutes prohibit the publication of certain particular items, for instance the details of divorce proceedings; and the publication of seditious, blasphemous, obscene or libellous matter is subject to the ordinary consequences of the law.

In the Irish Free State a Censorship of Publications board was set up in 1929, with power to prohibit any publications containing indecent or obscene matter and also any publications advocating birth control; and members of the public are entitled to complain about books or periodicals containing matter which they consider ought to be prohibited. In its report for the year 1947, however, the board said: "The Board noted with surprise and disappointment that a number of complaints concerned books which had been prohibited, sometimes for a long period. These complaints covered books obtained from bookshops in Dublin and elsewhere, and from circulating libraries in various parts of the country. The Board, while being aware of the difficulty of securing a complete enforcement of its decisions, is left in consequence with the uncomfortable feeling that much of its work is at present being done in vain."

Stage Play Censorship.—From its early beginnings in the 16th century the English theatre was placed under royal control; and in spite of many determined attempts to abolish it, the censorship of stage plays continued to survive under the direction of the lord chamberlain, one of the high officers of the royal household, to whom it was first assigned by the Licensing act, 1737.

The present powers of the lord chamberlain are defined by the Theatres act, 1843, and include the power to forbid the acting of any stage play whenever he is of the opinion that "it is fitting for the preservation of good manners, decorum, or of the public peace to do so"; moreover, for the purpose of this censorship, a stage play means any entertainment on the stage of a dramatic character. This statute, which applies to the whole of Great Britain, makes it a criminal offense to act a stage play not submitted to the examiner appointed by the lord chamberlain. Ireland was never regarded as falling within the lord chamberlain's jurisdiction; the drama there has always been regulated by special legislation.

In 1865 a petition was presented by 21 dramatic authors of note for the abolition of the lord chamberlain's censorship, but a select committee of both houses of parliament recommended no change. In 1907, after much intermediate agitation had taken place, 71 authors (including J. M. Barrie, Thomas Hardy, George Bernard Shaw and Algernon Charles Swinburne) joined in a letter to the *Times* (London) and their language did not err on the side of mildness. In consequence another select committee was appointed. Its report, published in 1909, recommended that

"it should be optional to submit a play for licence, and legal to perform an unlicensed play whether it had been submitted or not"; but the report was not followed by legislative action. In 1949 a private member's bill for the repeal of the censorship of plays was introduced in the house of commons, and its second reading was carried by 76 votes to 37; it did not however succeed in reaching the statute book.

Pragmatically regarded, the lord chamberlain's censorship may be said on the whole to have justified itself. Playwrights have opposed it strongly because they resent what they consider the examiner's arbitrary interference with the free expression of their art; theatrical managers on the other hand have been strong in their support of it because, without the lord chamberlain's licence, the successful run of an expensively produced play might be jeopardized by the activities of local councils and common informers.

Film Censorship.—The censorship of films is exercised by the British Board of Film Censors, a private body which has no constitutional or statutory authority. The board was set up in 1912 by the film industry itself to regulate the industry's own standards of morals and propriety.

The official influence of the British Board of Film Censors on films shown to the public had its origin in the fact that films are made of highly inflammable material. This led to the passing of the Cinematograph act, 1909, which, in order to ensure the public's safety from fire, made it a criminal offense throughout the United Kingdom to exhibit films to the public except in buildings inspected and licensed by the local county council. It was later established, as the result of various decisions of the high court, that the terms of the statute gave the county council power not only to see that there were adequate means of escape in cases of fire but also to impose all sorts of other conditions, in respect of the licensed buildings, such as the banning of particular films (whether inflammable or not) and the prohibition of Sunday opening; and it became the almost universal practice for the county council's licence to be granted on condition that no film be shown unless it has been certified for public exhibition by the British Board of Film Censors. All these arrangements arose out of the provisions of the Cinematograph act, 1909. The Cinematograph act, 1952, widened the power of film censorship in the United Kingdom and extended it to noninflammable films.

In the republic of Ireland, films are censored by the official censor of films, appointed by the ministry of home affairs.

Television and Broadcasting Censorship.—As stated above, a drama is subject to the censorship of the lord chamberlain if it is acted on the stage and (in effect) to that of the British Board of Film Censors if it is shown in a cinema. The same drama shown on a television screen would not be subject to censorship, except, of course, that television is under the control of the British Broadcasting corporation.

Broadcasting and television in the United Kingdom constitute a government monopoly, for which the postmaster general is responsible to parliament, and the monopoly is operated by the B.B.C. under licence from the postmaster general. This enables the governors of the B.B.C. to censor anything which is broadcast or televised; but the ultimate power (not exercised in peacetime) lies with the postmaster general, who may require the corporation to refrain from sending out any particular item.

Postal and Telegraph Censorship.—Posts and telegraphs in the United Kingdom are a government monopoly; and the crown has the power, recognized and preserved by section 56 of the Post Office act, 1908, to detain and open any postal packet. This power is not exercised in peacetime except to prevent obvious breaches of the law, such as the sending of obscene matter through the post. In wartime it enables the government to impose a complete censorship on all incoming and outgoing mail. The government has similar powers under the Telegraph acts over all forms of telecommunication. (T. S. Pe.)

Wartime Censorship.—In 1544 a royal proclamation of Henry VIII ordered, under pain of imprisonment, that all books containing news of his majesty's army in Scotland should be brought in and burned, doubtless because the published account of the campaign was displeasing to the king. But it was not until the Crimean War that the need was seen for preventing the publication of news because of its value to the enemy. Lord Raglan, the commander of the British forces at Sevastopol, complained that a war correspondent's dispatch, published in the *Times* of Oct. 23, 1854, had given away invaluable details to the Russians; and a circular letter was consequently sent by the war office warning newspaper editors of the danger in publishing dispatches from their correspondents at the front and urging them to expunge such parts of the dispatches "as they might consider calculated to furnish valuable information to the enemy."

No actual British censorship of the press was set up until World War I. But already in 1913 the admiralty and the war office had in anticipation reached an agreement with the press to set up the joint Admiralty, War Office and Press committee; and the press undertook to respect the warnings (or "D. notices" as they were called) issued by the committee and accordingly "to withhold from publication information the exclusion of which from the papers appeared to the department concerned to be desirable in the national interest." On the outbreak of war in 1914 an official press bureau was set up, the functions of which were: (1) to issue official communiqués and thus to supply the press with "a steady stream of trustworthy information" about the war; and (2) to censor the items which the newspapers submitted of their own accord for censorship in fulfilment of the arrangements made between the government and the press.

The censorship of the press was on a voluntary basis throughout; and, as the government had no peacetime powers of control over it, the only sanction which lay behind the censorship was that of the wartime Defence of the Realm regulations, which made it an offense to publish "without lawful authority" any military information or any information directly or indirectly useful to the enemy. Information which had been passed for publication after submission to censorship by the official press bureau was information published with lawful authority; and the imprimatur of the official press bureau accordingly relieved the editor of a newspaper from liability under the Defence of the Realm regulations. Nevertheless the regulations of 1914 created an absolute prohibition on the publication of military information unless it had been passed by the official press bureau; and in 1918 the editor of the *London Morning Post* was prosecuted and convicted for publishing information in contravention of the regulations, although it was proved in his defense that it was already known to the Germans.

On the outbreak of World War II in 1939, defense regulations made similar provisions, subject however to the new and important condition that no person was to be found guilty of a contravention if he proved that the publication was not likely to prejudice the defense of the realm or the efficient prosecution of the war. Not only therefore did the imprimatur of the censorship relieve an editor from liability; but he could, at his own risk, publish also with impunity information stopped by the censorship, if he could later convince a magistrate that the safety of the realm or the efficient prosecution of the war had not been prejudiced. In spite of this freedom and notwithstanding the enormous volume of news published there were between 1939 and 1945 only four prosecutions for infringement of the censorship regulations. Security in these matters rested not on the defense regulations but on the agreement with the press of 1913: under this editors voluntarily undertook to respect the "defense notices" issued by the press censorship division of the ministry of information. Even in wartime the United Kingdom never knew the system adopted in so many other countries, whereby the whole of a book or a newspaper had to be submitted for the government's approval before it was printed.

Broadcasting, Film and Postal Censorship.—World War II was the first war in which news was broadcast and in which there was extensive publication of news by the medium of newsreels in cinemas; and, in the interests of national security, both these means of communicating information were submitted to the same censorship at the ministry of information as that applied to printed matter.

In World War I the "postal censorship" and the "cable censorship" were two branches of the war office; in World War II a separate department, the "postal and telegraph censorship," was set up.

During both world wars the censorship of letters and telecommunications was a vast network designed to defeat the enemy's attempts to extract information from behind the lines: it necessitated a strict examination of any suspect documents which might convey, by the use of codes, ciphers, special inks or any other devices, messages intended for the enemy. As a result many enemy agents were

apprehended and channels of communication closed. Communications obtained from enemy agents were in many cases altered so as to convey false information and then allowed to proceed. In addition letters and telegrams destined for countries contiguous to the enemy's were censored if they contained details of air raids or other information likely to be useful, although the senders may not have meant to help the enemy.

In both world wars the censorship of press mail and press telegrams was undertaken by the press censors and not by the postal and telegraph censors. (G. P. T.)

THE UNITED STATES

Preventive censorship, or the examination before publication of some form of communication (book or periodical, theatrical presentation, motion picture or radio broadcast) by an official licensing agency with power to approve, change or suppress the offering, has not been a characteristic American method of controlling the public mind or morals. Freedom of communication has generally been limited by postpublication prosecutions under laws proscribing certain communications as dangerous to public order, public morals or the security of the state. The threat of punishment and at times extraordinary extensions of judicial or administrative prerogatives constitute a punitive censorship that through fear enforces silence or breeds conformity.

Censorship in the American Colonies.—Preventive censorships have existed from colonial days to the present. The first printing press (Cambridge, 1638) was licensed by the Massachusetts theocracy. Religious books were censored until 1695, and after that special manuscripts were submitted to authority. The crown governors acted as licensers, and from 1686 to 1730 were instructed in their charters that "no book, pamphlet or other matter be printed without your especial leave and consent." The first newspaper, *Publick Occurrences Both Forreign and Domestick*, Boston, 1690, was suppressed after one issue. "Published by Authority" appeared on newspapers until about 1725. Since, prepublication censorship has existed only in wartime. The trial of John Peter Zenger, publisher of the *New York Journal*, in 1734, ended one kind of postpublication control by establishing the right of the jury to determine not only the fact of publication, but whether the words constituted a libel. The judge had hitherto claimed this dangerous prerogative. Since 1776 the state constitutions have almost universally guaranteed freedom of the press. In 1791 the 1st amendment to the constitution of the United States declared: "Congress shall make no law . . . abridging the freedom of speech or of the press" This ended all censorship. The courts agreed with the narrow dictum of Blackstone: "The liberty of the press consists in laying no previous restraints upon publications, and not in freedom from censure for criminal matter when published." (*Patterson* v. *Colorado*, 205 United States 454, 1907). But liberals, showing that precensorship had ended by 1730, have claimed that the 1st amendment must also protect free expression against "abridging" by police powers, after publication. After World War I the supreme court set up two great new safeguards of liberty. (1) In 1919 the court declared that the test of punishable words is whether their nature and the circumstances of their use "create a clear and present danger that they will bring about the substantive evils Congress has a right to prevent." (*Schenck* v. *United States*, 249 United States 47). The dangerous and outworn test of some remote "bad tendency" was by-passed. (2) In 1925, and subsequently, the court declared that the liberties of the 1st amendment were secured to the citizen against infringement by the states. The principle that James Madison had failed to get into the Bill of Rights, the justices wrote in: "We may and do assume that freedom of speech and the press are among the fundamental personal rights and liberties protected by the due process clause of the Fourteenth Amendment." (*Gitlow* v. *New York*, 268 United States 652).

Military Censorship.—War has generally re-established some principle of censorship. During the flurry with France in 1798, the Federalist party passed the Sedition act, which provided punishments for publications, oral or printed, that reflected on the government, promoted sedition or resistance to law. About ten persons, chiefly Republican editors, were convicted. The issue defeated the Federalists in 1800, and the law lapsed, without interpretation by the supreme court. Pres. Thomas Jefferson released every person under punishment or prosecution. During the Civil War (1861–65) the postmaster general barred from the mails several Northern periodicals opposed to the war. Certain editors were imprisoned on the mere order of the secretary of state or of war. Newspaper offices in Missouri, Chicago and New York city were actually seized by troops, and issues of papers suppressed. Certain correspondents had to submit articles to the military for approval. Telegraphic dispatches were censored in Washington. In Colorado, 1904, and West Virginia, 1912, state militia under so-called martial law arrested editors, or suppressed and censored labour papers during strikes. In World War I the press established a voluntary censorship. Informal control was exercised through a governmental instrument, the Committee on Public Information. The newspapers, press associations and other organizations co-operated to prevent the disclosure of military or naval information, or matter calculated to weaken public morale. Strict military censorship was applied to news from correspondents with the U.S. forces abroad. Foreign language periodicals in the United States were regulated by the Trading with the Enemy act (United States Compiled Statutes, 1918, 3,115½ j.) and had to file English translations. The department of justice declared, however, that the constitutional right of free speech existed in war as in peace.

In World War II the army and navy enforced compulsory censorship in areas under their control. The press criticized some rulings as unreasonable or discriminatory. On Dec. 19, 1941, Pres. Franklin D. Roosevelt (under the First War Powers act) established the Office of Censorship, with Byron Price as director, to meet two needs. (1) It exercised a compulsory security censorship, with penalties, on communications each way between the United States and foreign countries, especially by mail, cable or radio. Domestic publications were previewed for adaptation for export, sometimes even as to opinion content. Correspondents complained that nonmilitary news dispatches critical of U.S. policy on internal race or labour controversies were held up to avoid unfavourable repercussions abroad. Such controls were gradually relaxed. (2) The office set up a voluntary self-censorship by the domestic press and radio, based on Codes of Wartime Practices for each medium (Jan. 15, 1942, with later revisions), listing the kinds of information that could aid the enemy. These included, for example, troop movements, weather news, some advertising and reports on uranium production and covered unforeseen risks of messages via open microphones and request programs. The industry associations of both media co-operated; editors approved especially the speedy expert advice and clarification on individual problems from the office. No penalties were provided, no restraints on advocacy or political debate were imposed. Potential sanctions did exist—possible imposition of statutory censorship, control of news gathering, public report of violations—but were not invoked. The censorship worked because of the patriotic resolve of all interests not to aid the enemy and not to curtail freedom of opinion.

The Postal Censorship.—The so-called "postal censorship" is based on the power of the postmaster general to deny the second-class mailing privilege to publications that contain matter forbidden by certain federal statutes. The idea was born in 1835 when southern representatives in congress tried to pass a law forbidding federal postmasters from distributing "incendiary" matter advocating the abolition of Negro slavery in states that had banned such agitation. The law failed of passage, but in fact southern postmasters never delivered abolitionist papers. In the Civil War, a congressional committee upheld the postmaster general's power to bar recalcitrant northern journals from the mails. In 1868 lottery information was forbidden the mails by law, and in 1873 the famous "Comstock law" against obscene matter and contraceptive information was passed. This produced many prosecutions and punishments. Later, matter furthering frauds or the sale of alcoholic liquors or advocating criminal anarchy was proscribed by statutes. The final extension came during World War I when title XII of the Espionage act of June 15, 1917, made nonmailable any matter violating these specifications in title I:

(i) making false statements or reports with intent to interfere with the operations or success of the armed forces of the United States; (ii) wilfully causing or trying to cause insubordination, disloyalty, mutiny, or refusal of duty in the armed forces; (iii) wilfully obstructing the recruiting or enlistment services of the United States.

Heavy penalties (fine or imprisonment) were to be imposed on those attempting to use the mails for these purposes. The Sedition act, May 16, 1918, added nine other specifications, such as obstructing the sale of United States bonds; publishing language intended to cause scorn or contempt for the government, constitution, flag or uniform, urging curtailment of the production of war needs. The postmaster general could act on "evidence satisfactory to him." Under these acts, the mailing privilege was denied to one or more issues of two Socialist dailies, to many Socialist and radical magazines and even journals of liberal opinion. Periodicals had their second-class privilege absolutely suspended. Books and pamphlets were barred. More than 100 publications were interfered with to some degree—the widest interference with the press in the nation's history.

The courts have always held that these statutes do not limit freedom of the press, usually denying review of such bans, as they are held legitimate exercises of an executive function. The post office avoids the position of a censor by refusing to define objectionable matter in advance. The liberal view holds that since the government enjoys a postal monopoly, the publication denied this preferential rate (granted publications to encourage the dissemination of knowledge) cannot compete with those enjoying the privilege.

Censorship of Motion Pictures.—The federal government under the interstate commerce power, forbade the importation or transportation of prize fight films and lewd or obscene films. (Penal code, section 245, revision of June 5, 1920.) Few cases arose under these statutes. Proposals to establish a board of censors in the office of education were defeated. Preventive censorships continued to exist in Pennsylvania (1911), Ohio (1913), Kansas (1914), Maryland, Virginia and New York. Boards of appointed "well-qualified" persons, receiving salaries, preview all films for public exhibition and may ban an entire film, delete scenes or words, or prescribe revision. The supreme court held such censorships constitutional. Since certain of the large states with censorships are important sources of revenue, the producers edit all films to conform to their codes, and thus six states influence the character of the films offered in all the states. Since 1935 the Catholic Legion of Decency has had considerable influence on the character of

film offerings through its regularly published listings of approved and disapproved films. The producers set up a voluntary self-censorship under a strict code. Certain municipalities control motion pictures through police powers, especially through licensing ordinances for exhibitions. Cases arose on films dealing with birth phenomena and those viewed as inflammatory of race, religious or international controversy.

Censorship of Radio Broadcasting.—The Federal Communications commission, created by public law 416, June 19, 1934, was empowered to license public broadcasting stations to use wave channels and time periods as "public interest, convenience, or necessity requires" (section 303). Its censorship powers were explicitly limited to prohibiting profane or obscene language and to enforcing equal rights for legal candidates for public office. It intervened in cases of alleged obscenity or profanity and to correct advertising abuses. Its acts revealed no political motives. Liberals declared the commission exercised an indirect censorship, since station owners, required to secure renewal of licences at short intervals, would conform to the program standards implied by the commission's acts or utterances. Liberals opposed as legally unwarranted the commission's order (May 1939) that short-wave broadcasts "reflect the culture of the United States and international good will." As for the stations, they scrutinize materials before broadcasting them, at times censor offerings and even bar speakers. Labour and Socialist organizations charged that these precautions, defensible as preventives of libelous or scandalous utterances, sometimes limited their air freedom. The self-regulatory code adopted by the National Association of Broadcasters (1939) set high standards for the handling of controversial issues and religion with fairness and freedom.

Censorship of Plays and Books.—No formal censorship of the theatre has ever existed in the United States. Interference has been by local prosecutors or the police, who have, on complaint, viewed exhibitions and sometimes ordered them withdrawn or amended, or instituted proceedings against both producers and actors that have in certain cases resulted in fines or jail sentences. The New York statute (1927) included matter dealing with sex perversions under obscenity. The suspension of the licences of theatres offering alleged immoral burlesque shows revealed the commissioner as a potential censor.

Interferences with the distribution of books and periodicals have been under the postal law, the customs law (later providing for judicial review) and local morality ordinances. Liberal court decisions have limited the activities of the New York Vice society against alleged pornographic publications that in the past had suppressed books of admitted literary worth. In Boston, the Watch and Ward society, by agreement with the prosecutor, listed books for the sale of which booksellers might be prosecuted. Later the police established their own censorship under which a number of volumes were proscribed, although many were sold everywhere else in the United States.

CENSUS. In modern usage, primarily denotes the periodical survey of the number and condition of the people—more fully described as "census of population" where necessary to distinguish it from the census of production, census of agriculture and similar institutions.

History.—Numberings of the people and national stocktakings are known to have been conducted from very ancient times. The Old Testament records the enumeration at the Exodus of the fighting strength of the Children of Israel and of the non-military Levites, and the famous enumeration of fighting men, conducted by Joab at the command of David, on which the divine wrath was visited. Records survive of a complete cadastral survey and census of Babylonia comprising agriculture, stock and produce, which appears to have been carried out for fiscal purposes in the third millennium B.C., and in the Persian empire, in China and in Egypt similar surveys are known to have taken place for the assessment of fiscal, military or labour liabilities. A most notable example was the Roman census, from which the modern institution derives its name: under this system the members and property of every family were enumerated quinquennially for the purpose of determining their civil status and corresponding liabilities. Dating from pre-republican Rome, the Roman census was extended by Augustus in 5 B.C. to the Roman empire and thus covered the whole of the civilized world of those times. The Roman census perished in the wreck of the Roman empire. Feudalism may have rendered the revival of census-taking, even when practicable, less necessary; and superstition may have contributed to its abeyance. The Christian Church remembered the punishment of Israel; and even in the British House of Commons in 1753 it was possible for the fear to be expressed that a numbering of the people would be followed by "some great public misfortune or epidemical distemper." It is, of course natural that objections to taxation or military service should assume the cloak of religious scruple; but there must have been more than this. It is impossible not to infer that in the Old Testament story and in the purificatory sacrifice concluding the Roman census folk-memory lingered of a primitive *taboo*. And these speculations receive interesting support from the announcement, in connection with the Kenya census of 1926, that the authorities anticipated trouble with certain tribes among whom there was a strict *taboo* against counting either themselves, their wives or their cattle.

Thus, apart from undertakings such as Charlemagne's Breviary and the English Domesday Book (an inquest upon geld assessments) there was a long interval in census history until the mid-17th century, when a periodical census of the modern type was instituted in La Nouvelle France (Quebec) and Acadie (Nova Scotia). Enumerations of population took place in several of the German States from 1742 onwards, in Sweden in 1748, Denmark in 1769 and Spain in 1787. In Great Britain, after proposals had been made and defeated in 1753, the census was definitely established in 1801. From these and similar beginnings in other countries the institution of the census rapidly gained a permanent place in the organization of nearly all modern States, the most recent convert being Turkey in 1927. It will be seen that the precursors of the modern census were almost wholly executive operations discharging essential functions of government such as military recruitment and taxation. But in the long interval which preceded the revival these functions cut for themselves other channels of administration; and when inquests and surveys upon a national scale were again resumed it was with a very different object, viz., to supply knowledge for the guidance of public policy and to "substitute certainty for conjecture" upon the vexed questions of fact which are vital to political action and foresight.

CONCEPTION AND EVOLUTION OF MODERN CENSUS

The census, as now conceived, has two main objects. It provides an instantaneous picture of the community—a cross-section of the body-politic exhibiting its constitution at the point of time when it is made. It thus affords knowledge of numbers and conditions which is valid for the particular point of time and, with approximations, for adjacent periods. But all things are subject to change; and knowledge of the force and direction of changes in the community are even more important than the facts at any given date. A single sounding will disclose what depth of water is below the keel; but not without repeated soundings is it known whether the water is shoaling, and how rapidly. Hence in the modern census each enumeration is conceived not only as a source of static knowledge but as an item in a consecutive series. From the succession of these alone can be ascertained and measured those great drifts and currents in the national life which, whether deemed good or evil, whether resistible or irresistible, must at least be known and reckoned with.

House to House Visitation.—The first among the questions upon which certainty was deemed requisite was the number of the population. Such a numbering entails a house-to-house visitation coupled with enquiries of the inmates. This process (primitive, but not to be bettered) affords opportunities, on the one hand, and imports limitations on the other, which have substantially determined the scope and evolution of census-taking. In the first place, the itinerary may be planned so as to group the dwellings visited according to any designed arrangement of boundaries: thus information obtained respecting the population of each areal group may be separately recorded and becomes available, not only as a component part of the national total, but also by itself, or as a component part of larger areal units, for the purpose of exhibiting the local distribution of that total. Further, the need to ensure that no dwelling is omitted leads to a record being made of all premises on the itinerary. It is but

a step to include particulars of each dwelling, *e.g.*, whether inhabited or vacant, and the number of its rooms, thus affording, in combination with other material, statistics as to housing conditions, overcrowding, etc. The convenience of obtaining particulars from one spokesman on behalf of each family or household leads to a system of household returns which themselves afford a count of such families. But the germ of the fertile elaboration of census enquiries is to be found in the fact that the information is obtained by direct enquiry of the persons concerned, thus permitting of the inclusion of every subject on which the individual can reasonably be expected to state his own position and that of his dependants. Age may be asked and given: the relationship and marital status of persons comprised in the household group can be described. Birthplace and nationality may be stated. A further group of personal particulars has furnished a great body of statistical material relative to occupation and industry. Every occupied person can state his job in terms which permit of precise occupational classification. And in addition to stating that he is, for example, a crane-driver, he can add that he is employed by a firm of brewers, thus enabling himself to be classed to the industry which he serves. Other enquiries are regularly included where the conditions render them suitable, such as religion, language spoken and literacy. Comparatively complicated enquiries may be included such as the "fertility of marriage" enquiry in English, French, Netherlands, Spanish and Norwegian censuses (date of marriage: number of deceased and number and ages of living children of the marriage).

The Personal Aspect.—The common element in all these enquiries is that they are personal. It has been suggested that the whole field of statistics can be viewed as concerned with either *personnel* or with *material:* this is not an entirely watertight division, but it accurately represents an important difference between the main points of view from which statistical information is sought and studied. The census as an instrument for the collection of information is predominantly concerned with aspects of *personnel*, and covers the major portion of that province. It is unable to elucidate any subject except as an attribute of the individual man or woman. The inclusion of agricultural statistics in some countries is an apparent exception: but such enquiries may be in a sense an extension of the record of dwellings. The homestead is visited; it is noted that so many acres of arable, etc., are annexed and that there is stock of a certain kind and number. This is consistent with the census procedure, which must locate as it counts: it cannot deal with wealth which is everywhere and nowhere. Subjects such as exports and imports are clearly out of the picture. But there are some limitations in the field of personal attributes. The enquiry must be capable of being simply put and answered. Intrinsically there is nothing to prevent the use of the census to ascertain the distribution of the national wealth or income; but the preparation of a statement in the form necessary to furnish the answer upon a uniform basis would be beyond the power of most individuals. If all particulars needed for the calculation were asked they would need a census schedule to themselves; and if the final figure alone were to be given there would be no security that it was properly arrived at. An enquiry of all wage-earners as to the rate of pay received (as in the Spanish census) would not be subject to the same objection.

Difficulty of Verification.—But in many countries another general limitation would apply. Census returns cannot be verified, in view of the magnitude of the operations; and it is useless to make any enquiry respecting which individuals may have any conscious motive, real or fancied, for suppressing or distorting the facts. Hence information which in the popular apprehension might be used by the authorities for enforcing individual liabilities, such as taxation, cannot profitably be asked; and truthful information upon subjects, such as illegitimacy, which are felt to be delicate is often unobtainable owing to a fear of it becoming public. These considerations have tended to emphasize the character of the modern census as a source of abstract statistical information only. Whatever expectations may have been formed in the early days of the census revival as to its incidental utility for executive purposes, census administrators have had to choose between making it an effective instrument for the collection of statistics only and making the worst of both worlds. Another minor limitation applies to the doubtful ability of the individual to give reliable answers to enquiries as to infirmities such as blindness, deafness, etc. Even if no bias due to prejudice arises, the terms employed are unavoidably indefinite; and the conditions themselves cannot be properly assessed save by trained medical judgment. It is becoming recognized that the census can afford little assistance of value in this sphere.

Advantages.—Within limitations the census has the peculiar and enormous advantage that all the varied attributes which it records are related to the individual to whom they jointly belong. Hence every type and class of information obtained can be presented in combination with every other type and class. If it be assumed, for the sake of illustration, that the collection of occupational data is omitted from the census and separately organized by means of returns from employers, information might still be forthcoming of the number of metal spinners, while the census would continue to state the number of men aged 49. But between the two sets of figures there would be a gulf; it would be impossible to obtain the number of metal spinners aged 49. Given, however, the inclusion of both enquiries in the census any combination of these and other results is possible; and a census enquiry, as distinct from one separately promoted, not only affords the desired information but adds a fuller and richer significance to all those which it supplements.

Utility of Census.—And as the scope of the census has expanded, so the sphere of its utility has been enlarged. It still discharges its original function as an intelligence service of the government by which it is promoted in both legislation and administration. Estimates cannot be framed, for example, of the money provision requisite in future for the payment of old age pensions, or of the school provision needed for the rising generation, without the help of census material. Social insurance schemes equally rely upon such material for their actuarial foundation. Electoral redistribution must be largely based upon population distribution; in South Africa constituencies are rearranged on the results of each census. Census statistics are the common tools and material of the business of government in ways too numerous to detail; but they are equally indispensable to the direction of State policy. In matters of defence the most pacific nation cannot afford not to know where it stands and whither it is tending. Questions of unemployment cannot begin to be considered without a knowledge of the industrial disposition of the people. Policy respecting migration still depends upon a recognition of the forces of population pressure which have so often changed the face of history. Knowledge of all these facts, even where not directly contributing to the solution of the problems of statecraft or state-policy, nevertheless forms a background against which they must be viewed. And for the public service in its widest significance the census provides material for research and study, helping to define and clarify the issues on the great questions to which there is as yet no agreed answer, and which, so far from having been admitted within the sphere of government responsibility, are but vaguely stirring in the conscience of the community. Not among the least of the services of the census is that which it renders to statistical method whereby, for example, mortality data may be converted into mortality rates, thus eliminating variables and reducing to a comparable basis a wealth of material which for many purposes would otherwise be useless.

CENSUS METHOD AND PRACTICE

Within the essential framework of the census system—house-to-house visitation coupled with enquiries—diversities in national practice are for the most part of little moment. But in one case, at any rate, a question of method is also a question of principle. Populations are represented in some countries *de jure*, in others *de facto*. A *de facto* enumeration, following the principle of the instantaneous picture, allocates individuals to the areas in which they are physically found at the census date, regardless

of their usual residences. A *de jure* distribution, on the other hand, is that which assigns the population to the respective areas of usual residence. Where populations are immobile, one set of figures serves both purposes: but in most industrially developed countries there is much, and increasing, population movement. It is usual in *de facto* enumerations to select a census date which so far as possible avoids population movement and on which *de facto* thus approximates to *de jure*: otherwise a *de facto* distribution is apt to be fortuitous and meaningless. But *de jure* as a norm is not valid for all purposes. What, after all, is the population of Blackpool? The number of its permanent winter residents, or its doubled or tripled complement of the holiday season upon whom so much of its existence and conditions depends? The great daily migrations between home and workplace raise a similar question: what, it may again be asked, is the population of the City of London—the 13,000 night residents, or the 400,000 who spend there a third of the most active portion of their lives? The truth is, of course, that there is no one answer: the purpose to be served determines the choice. But it will be clear, at any rate, that the meaning of the term "population" admits of some refinements.

Typical Systems.—The following outline will afford an indication of the scope and salient features of a few typical census systems. The English census has been hitherto decennial, though quinquennial powers are now available. The return is made by the householder, the enumeration being *de facto*. The schedule included the name, relationship to householder, age, sex, marital condition, orphanhood, birthplace, nationality, school attendance, occupation, industry, industrial status (whether employer, employee or working on own account), place of work, and number and ages of living children and stepchildren under 16.

France.—In France the census is quinquennial: a skeleton household return is made by the householder, supplemented by a separate return by each member. The former includes absent members and distinguishes temporary residents, thus providing for a *de jure* distribution. The individual schedule required name, sex, date and place of birth, nationality, marital condition, date of marriage, number of deceased and number and ages of living children of the marriage, usual residence (if temporarily present), literacy, and principal and secondary occupations, together with particulars of principal industry, industrial status, number of employees, or if employee, whether unemployed.

Italy.—In Italy the regular census is decennial: the return, which is made by the householder, includes particulars as in France for a *de jure* distribution. The schedule required the name, father's name (and whether alive or dead), relationship to householder, sex, date and place of birth, marital condition, literacy, principal and secondary occupations, whether owning property (distinguishing land and buildings), and nationality.

Germany.—Germany afforded an interesting example of a quinquennial census of alternately greater and lesser scope. The schedule comprised name, relationship to householder, sex, date of birth and marital status, with the distinctions requisite to provide a *de jure* distribution.

In 1925 these enquiries were supplemented by religion, nationality, mother tongue, last residence before World War I, principal and secondary occupations and industry and industrial status. The return is made by the householder.

Population Registers.—As seen in the foregoing examples, the frequency of the census series is usually decennial or quinquennial: the latter is generally deemed desirable on statistical grounds, but the census is an expensive and laborious undertaking. The attractive prospect has at times been indulged of the creation of population registers, containing in respect of each individual the particulars usually elucidated by the census, and accurately maintained, as a mirror of the people and of the passing phases of their lives, by reports of all changes in the personnel or in the particulars recorded about them. Given such registers, it has been urged, a census of the written records could be taken at any time, however frequent, to ascertain the current position regarding all or any of the recorded particulars without the labour and expense of the census visitation. The prospect, though attractive, is hardly realizable. Were it the case that all the requisite information is already available through one channel or another, nothing would be needed but their complete co-ordination for the maintenance of the registers. But in all countries there are great gaps in the essential information which could not be filled without a revolution in national habits or administrative machinery. Maintenance of the occupational and industrial record, for example, would involve a duty to notify change of occupation or employment in the case of every individual. Maintenance of accurate particulars as to local distribution would involve an obligation to report every change of address.

Population registers with a limited scope exist in some countries, such as The Netherlands, Belgium and Sweden; and many systems of public supervision require the registration of residence, arrival and departure. But such countries do not dispense with a census, and it seems doubtful whether removals are notified with sufficient completeness for statistical purposes. It will be clear that in Great Britain, at any rate, and in other countries similarly situated, the proposition would impose upon every individual a host of new obligations which though trifling in themselves would not be discharged without legal enforcement, and which, for want of sympathy with their purpose, would appear meaningless and oppressive. Such a system even if practicable would not be less laborious and costly than the census: it would be rigid, moreover, and lacking the valuable capacity of the census proper to experiment in new methods and new fields of enquiry on each successive occasion.

But while the census remains indispensable, the essential element of value in such proposals is well recognized, viz., the co-ordination of all continuously available demographic material, such as that of vital registration, with the periodical census results. The census population of a given date may be corrected by allowance for births and deaths over any subsequent period to show the population at a later date as modified by net natural increase or decrease. Allowance for the remaining factor of migration is necessary to complete the adjustment; and, given adequate records of migration, a population figure may thus be constructed which is as correct and authoritative as any census product. The process could be carried into further detail were the migration records fully complementary to the registration data. But if inadequate for the construction of fully authentic intercensal statistics, the supplementary sources are invaluable in the framing of estimates to bridge the intercensal gap. Vital registration is closely related to the census both in subject-matter and through their association for joint or mutual service; and cannot be ignored in any study of the census system.

See the articles POPULATION; BIRTH RATE; DEATH RATE and MARRIAGE RATE; *see* also official census publications of the respective national governments, and the United Nations, *Monthly Bulletin of Statistics* and *Demographic Yearbook*. (S. P. V.; X.)

UNITED STATES

The federal census, which began in 1790 and has been taken every ten years since under a mandate contained in the U.S. constitution, was the outgrowth of a controversy in the convention which prepared the document. Representatives of the smaller states as a rule claimed that the vote, and so the influence, of the states in the proposed government should be equal. Representatives of the larger states as a rule claimed that their greater population and wealth were entitled to recognition. The controversy ended in the creation of a bicameral legislature in the lower branch of which the claim of the larger states found recognition, while in the upper, the senate, each state had two votes. In the house of representatives seats were to be distributed in proportion to the population, and the convention, foreseeing rapid changes of population, ordained an enumeration of the inhabitants and a redistribution or reapportionment of seats in the house of representatives every ten years.

The provision of the constitution on the subject is as follows:

Representatives and direct taxes shall be apportioned among the several states which may be included within this Union according to their respective numbers, which shall be determined by adding to

the whole number of free persons, including those bound to service for a term of years and excluding Indians not taxed, three-fifths of all other persons. The actual enumeration shall be made within three years after the first meeting of the Congress of the United States, and within every subsequent term of ten years, in such manner as they shall by law direct.

In 1790 the population was reported classed as slaves and free, the free classed as white and others, the free whites as males and females, and the free white males as under or above 16 years of age. In 1800 and 1810 the same classification was preserved, except that five age groups instead of two were given for free white males and the same five were applied also to free white females. In connection with the census of 1810 an attempt was made to gather certain industrial statistics showing "the number, nature, extent, situation and value of the arts and manufactures of the United States." In 1820 a sixth age class was introduced for free white males, an age classification of four periods was applied to the free coloured and the slaves of each sex, and the number of aliens and of persons engaged in agriculture, in manufactures and in commerce was called for. The inquiry into industrial statistics begun in 1810 was also repeated and extended. In 1830, 13 age classes were employed for free whites of each sex, and six for the free coloured and the slaves of each sex.

The law under which the census of 1840 was taken provided for the collection of statistics on agriculture, manufacturing, mining, commerce and education, as well as on population—representing a tendency to make the census overinclusive which persisted through 1880.

The census of 1850 employed six schedules: for free inhabitants, for slaves, for deaths during the preceding year, for agriculture, for manufactures and for social statistics. The last asked for returns regarding valuation, taxation, educational and religious statistics, pauperism, crime and the prevailing rates of wages in each municipal division. It was also the first U.S. census to give a line of the schedule to each person, death or establishment enumerated, and thus to make the returns in the individual form indispensable for a detailed classification and compilation. The results of this census were tabulated with care and skill, and a preliminary analysis gave the salient results and in some cases compared them with European figures.

The census of 1860 followed the model of its predecessor with slight changes. When the time for the next census approached it was felt that new legislation was needed, and a committee of the house of representatives, with James A. Garfield, afterward president of the United States, at its head, made a careful and thorough study of the situation and reported an excellent bill, which passed the house, but was defeated by untoward influences in the senate. In consequence the census of 1870 was taken with the outgrown machinery established 20 years earlier, a law characterized by Francis A. Walker, the superintendent of the census, who administered it, as "clumsy, antiquated and barbarous." It suffered also from the fact that large parts of the country had not recovered from the ruin wrought by four years of civil war. In consequence this census marks the lowest ebb of U.S. census work. The accuracy of the results is generally denied by competent experts. The serious errors were of omission, probably confined in the main to the southern states, and especially frequent among the Negroes.

After 1870 the development of census work in the United States was steady and rapid. The law which had been prepared by the house committee for the census of 1870 furnished a basis for greatly improved legislation in 1879, under which the census of 1880 was taken. By this law the census office for the first time was allowed to call into existence and to control an adequate local staff of supervisors and enumerators. The scope of the work was so extended as to make the 22 quarto volumes of the tenth census almost an encyclopaedia, not only of the population, but also of the products and resources of the United States. Probably no other census in the world has ever covered so wide a range of subjects, and perhaps none except that of India and the succeeding U.S. census has extended through so many volumes. The topics usually contained in a census suffered from the great addition of other and less pertinent matter, and the reputation of the work was unfavourably affected by the length of time required to prepare and publish the volumes (the last ones not appearing until near the end of the decade), the original underestimate of the cost of the work, which made frequent supplementary appropriations necessary, the resignation of the superintendent, Francis A. Walker, in 1882, and the disability and death of his successor, Charles W. Seaton. The 11th census was taken under a law almost identical with that of the 10th, and extended through 25 large volumes, presenting a work almost as encyclopaedic, but much more distinctively statistical.

SCOPE OF CENSUS NARROWED

Competent discussion between 1890 and 1900 fastened on this point, and under the law of 1899 the scope of the census of 1900 was greatly narrowed. This was secured not by abandoning any of the numerous inquiries which had overloaded the two preceding censuses, but by dividing them into major and minor groups, the major group embracing those inquiries, population, vital statistics, agriculture and manufactures, for making which enumerators were needed in the field; the minor group embracing those which could be conducted by correspondence supplemented to a slight degree, if necessary, by field agents at strategic points. The law required the completion of the major inquiries in three years (the two preceding censuses had taken more than twice as long to finish) and postponed the minor inquiries until the major group was completed. The new law thus foreshadowed, but did not establish, an office functioning without interruption, and as a natural consequence of it, in 1902 the bureau of the census was made permanent. This important and salutary change was maintained in subsequent legislation.

In no field of census work has it been more beneficial than in that of vital statistics. The registration of births and deaths is under the jurisdiction of the states, only 11 of which had registration systems in 1900 adequate to meet the requirements for admission to the death registration area which was set up at that time. Model registration laws were formulated, however, and these were adopted and put into effect year by year in additional states until, in 1933, all the states were included in both death and birth registration areas, giving a complete coverage of the United States. Statistics of deaths and births compiled from state records are published by the bureau of the census in its annual volumes entitled, respectively, *Mortality Statistics* and *Birth, Stillbirth, and Infant Mortality Statistics*. Statistics of marriage and divorce were collected for the years from 1867 to 1906, for 1916 and for 1922 to 1932—the latter appearing in a series of annual reports. These reports were resumed on an annual basis beginning with 1940.

The census of 1910 was the first decennial census taken under the permanent census bureau. This census covered four subjects, namely, population, agriculture, manufactures and mines and quarries, many of the other subjects included in earlier decennial censuses having been taken care of either by annual reports, as in the case of vital statistics, or by inquiries conducted between the decennial census years, as in the case of the statistics of religious bodies and of benevolent and corrective institutions. The most significant additions to the list of questions asked on the 1910 population schedule, as compared with that of 1900, were mother tongue and ability to speak English, with special reference to the foreign-born; and for the gainful workers, industry as well as occupation, and unemployment. The data on gainful workers were tabulated by occupation in combination with industry, though only a limited publication was made, by reason of insufficiency of funds at the close of the census period. For a similar reason the unemployment data were not published at all. A new basis of distinction between urban and rural population, in which all incorporated places having 2,500 inhabitants or more were counted as urban (a definition which was used through 1940) was set up; and many details were added to the tabulations published for counties and the smaller cities.

The population census of 1920 was patterned closely after that of 1910, except for the omission of questions on unemployment and the introduction into the general tabulations of a new category,

namely the farm population, that is the population living on farms. (Dwellings or homes had been classified as farm and nonfarm in earlier censuses, from 1890, but no extended use had been made of this subdivision, nor any tabulations of population classified as farm and nonfarm.)

In order to expedite the publication of the new census data, the text in the main reports of this census was limited to such descriptive and explanatory matter as was required for the understanding of the figures. These reports were supplemented by more detailed analysis of important topics in a series of 12 monographs, which appeared at intervals during the decade.

In 1930 one significant question, namely, the value or rent of the home, was added to the population schedule; and there was a separate schedule on unemployment, going into this subject in far more detail than ever before. The 1930 reports were published, like those of 1920, with little analytical text. There were, however, many added details in the 1930 tabulations, including a tabulation of gainful workers by counties, increased age data for counties and the smaller cities, a brief classification of the population of townships and an entire volume devoted to statistics of families, in addition to two volumes on unemployment. The classification of the population as farm and nonfarm, introduced in a limited way in 1920, was carried much further in the form of an almost universal subdivision of the rural population into rural farm and rural nonfarm. Bulletins containing the final census counts for states, counties, townships or districts and incorporated places were published for all states before the end of the census year, 1930, these forming an advance showing of the data which later appeared as vol. 1 of the census reports. A second series, presenting much tabulated detail, and a series on unemployment were published before the end of 1931, followed closely by a series on occupations and a new series on families.

An important innovation in 1940 was the census of housing, which was taken in close connection with the census of population and in which were incorporated certain items previously a part of the population census reports, in particular, tenure and value or rent of home and mortgage debt. This census covered also various items descriptive of housing units, including exterior material, year built, type of structure and state of repair. There were also questions with regard to such facilities as plumbing equipment; water supply; and heating, lighting and refrigeration equipment. Some items from the housing census are published for the larger cities by blocks, this being the first instance in which census statistics have been published for such small areas. A new feature in the 1940 population census itself was the provision for asking a part of the questions with respect to 1 person in 20 rather than for the entire population, thus providing a 5% random sample as a basis for the tabulation of statistics. This device was introduced primarily to take care of additional questions for which there was no space on the main schedule. The sample questions included usual occupation (in distinction from present occupation), veteran status, social security registration, mother tongue, place of birth of parents and a group of questions on fertility. These additional questions were asked of those persons whose names fell on certain numbered lines of the main schedule Brief preliminary cards containing the basic items of colour, sex, age and work status were also punched from these selected lines and tabulated many months in advance of the date on which these important characteristics of the population could have been obtained from the complete tabulation. New questions contained on the main population schedule included one on highest grade of school completed (which replaced the old question on illiteracy) and a question on place of residence in 1935, which formed the basis for the first direct statistics of population migration. The section on work status provided the basis for a count not only of persons seeking work but also of those employed on emergency work projects, as well as of those employed in private industry or on regular government work. Persons not in the labour force were for the first time classified into significant categories, such as housewives, students, persons unable to work, etc.; and there were supplementary questions on extent of unemployment, number of weeks worked in 1939 and amount of wage or salary income during 1939. Extensive and very significant reports on fertility in 1940 and 1910 were published, based partly on questions on the number of children ever born to each ever-married woman, in the sample section of the 1940 census schedule, and partly on similar questions on the 1910 schedule.

The 1950 census was in most respects similar to that of 1940. The sample was increased to 20%, in order to provide usable data for smaller areas; the question on mother tongue was omitted, and of course that on emergency employment, since there were no persons in that status in 1950; the data on migration were obtained through a question on residence one year prior to the census (rather than five years earlier, as in 1940); and the questions on income were expanded to include total income from all sources, that is, not only wage and salary income (as in 1940) but also income from one's own business or farm, and income from "all other sources." The questions on education, migration and income were transferred to the 20% sample section of the schedule, along with several of the less important housing items.

There were two significant changes in definition. First, the urban area was expanded to include not only incorporated places of 2,500 or more, as in 1940 and earlier, but also: (1) the thickly settled suburban area or "urban fringe" around each city of 50,000 or more; and (2) various unincorporated places of 2,500 or more—some of which had been arbitrarily included in 1940, however, under special rule.

The newly defined urban population exceeded what would have been classified as urban under the 1940 definition by about 8,000,000 or about 9%.

The farm population classification, on the other hand, was somewhat reduced, by excluding from the count considerable numbers of households which, while occupying dwellings nominally located on a farm, paid cash rent for these dwellings. The justification for this change was that, once a house and a plot of ground were rented out for strictly residential purposes, the plot of ground ceased to be a part of a farm. (A farm had long been defined as a piece of land which is farmed, that is, used for the production of crops or livestock products.)

The later and more accurately defined farm population was smaller by about 2,000,000 than what had been expected under the old definition.

The federal census has long made periodic reports on agriculture and manufactures. In 1925 a mid-decade census of agriculture was introduced, somewhat limited in scope. A census of manufactures formed a part of the decennial inquiry down to 1940, with additional inquiries within the decade, sometimes quinquennial and sometimes biennial. Censuses of "distribution" or "business" were taken in 1930 and 1940. Legislation enacted in 1948 provided that a census of manufactures and a census of business (including service activities as well as wholesale and retail trade) be taken in 1954 and every five years thereafter. The dates were specifically set outside the decennial census periods, so as to distribute the work load of the census bureau more evenly over the decade. (W. F. W.; L. E. T.)

CENSUS OF AGRICULTURE: *see* AGRICULTURE: *Agricultural Statistics.*

CENSUS OF PRODUCTION: *see* PRODUCTION, CENSUS OF.

CENT. A small copper or bronze coin. In the United States and Canada, it is the one-hundredth part of a dollar, approximately equivalent to a British halfpenny. In Holland the guilder is divided into one hundred cents.

CENTAUREA, a genus of the family Compositae, containing about 500 species, almost all natives of the Old World, with the principal centre in the Mediterranean region. The plants are herbs with entire or cut, often spiny-toothed, leaves and ovoid or globose involucres surrounding a showy head of tubular, oblique or two-lipped florets, the outer of which are usually large and neuter, the inner bisexual. Four species are native in Great Britain. *C. nigra* is the knapweed, common in meadows and pastureland; *C. cyanus* is the bluebottle or cornflower, well-known as a weed, much grown as a garden annual and the national floral emblem of Germany; *C. calcitrapa* is the star-thistle, a rare plant with

rose-purple flower-heads enveloped by involucral bracts which end in a long, stiff spine.

In eastern North America, in addition to the species mentioned, the brown knapweed (*C. jacea*), the scabious knapweed (*C. scabiosa*), the Tirol knapweed (*C. vochinensis*), the spotted knapweed (*C. maculosa*), the yellow star-thistle (*C. solstitialis*) and the rayless centaury (*C. melitensis*) are more or less extensively naturalized. On the Pacific coast *C. melitensis*, there known as Napa thistle, is a troublesome weed, especially in California, as is also *C. solstitialis;* less pernicious are the star-thistle, the blue-bottle and the Turkistan thistle (*C. repens*). The only native North American species, the basket-flower or American star-thistle (*C. americana*) is a robust annual 2 ft. to 6 ft. high, with very showy rose-coloured or purplish flower-heads, 3 in. to 5 in. across. It is found in dry plains from Missouri to Louisiana, and westward to Arizona and Mexico, and is also grown as an ornamental plant.

The best-known garden plants are a dusty miller (*C. cineraria*), the bluebottle (*C. cyanus*), the sweet sultan (*C. moschata*) and the mountain bluet (*C. montana*).

CENTAURS (Gr. *κένταυροι*), in Greek mythology, a race of beings part horse, part man, dwelling in the mountains of Thessaly and Arcadia. The centaurs are usually said to be the offspring of Ixion and Nephele. They are best known for their fight with the Lapithae, caused by their attempt to carry off Deidameia on the day of her marriage to Peirithous, king of the Lapithae, himself the son of Ixion. In later times they are often represented drawing the car of Dionysus, or bound and ridden by Eros, in allusion to their drunken and amorous habits. Their general character is that of wild, lawless and inhospitable beings, the slaves of their animal passions, with the exception of Pholus and Cheiron.

They are variously explained by a fancied resemblance to the shapes of clouds, or as spirits of the rushing mountain torrents or winds, etc. Perhaps the likeliest suggestion is that they are a distorted recollection of some savage tribe, reputed by its neighbours to be composed of monsters. Like the defeat of the Titans by Zeus, the contests with the Centaurs typified the struggle between civilization and barbarism. In early art they were represented as human beings in front, with the body and hind legs of a horse attached to the back; later, they were men only as far as the waist.

See Roscher's *Lexikon, s.v. Kentauren;* P. V. Baur, *Centaurs in Ancient Art* (Berlin, 1912); G. Dumezil, *Le Proleme des Centaures* (Paris, 1929).

CENTAURUS (the "Centaur"), in astronomy, a southern constellation (invisible in northern lands) rich in bright stars and globular clusters. The two stars α, β are known as the southern Pointers since they point to the Southern Cross. One of these, α Centauri, is the third brightest star in the sky, and it is found to be our nearest neighbour; the distance is 4 light years (parallax $=0.75''$). It is a double star of which the brighter component is almost a replica of the sun, having nearly the same brightness and mass but slightly lower surface temperature; there is also a third widely separated faint companion called Proxima Centauri, because it is slightly nearer to us than the main star.

The constellation also contains ω Centauri which is the finest example of a globular star-cluster; it is probably the nearest object of this class, but the distance is no less than 20,000 light years. Photographs of it show more than 6,000 stars within a circle of 20′ diameter, but the number must be much greater. (A. S. E.)

CENTAURY, any herb of the genus *Centaurium* family Gentianaceae; also, especially in America, the milkwort (*Polygala paucifolia*). The common centaury of Europe, *C. confertum*, occurs in dry pastures and on sandy coasts in Great Britain and is often cultivated for ornament.

The centaury presents many varieties, differing in length of stem, degree of branching, width and shape of leaves, and laxity or closeness of the inflorescence.

CENTENARY, the celebration of an event after a hundred years. The word "centennial" (from Lat. *centum*, a hundred, and *annus*, a year), though usually an adjective as in "the Centennial State," the name given to Colorado on its admission to statehood in 1876, is also used as a synonym of centenary.

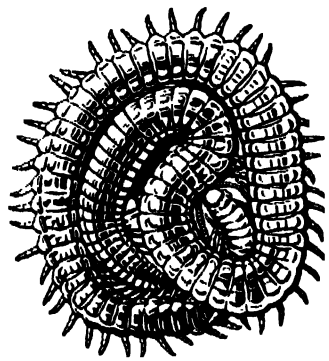
CENTERING, a term applied to the erection of temporary woodwork to support arches, etc., while they are setting. Thus, in the case of an arch, the carpenter forms a "turning-piece" shaped to take the bricks or masonry, and properly tied and braced. This is strutted in position, when the arch is completed by the bricklayer or mason. As soon as the work is set, the centering is carefully removed, which is called "striking the centering." The same method is used in building brick sewers. The origin of the word "centering" is obvious from the primary use in centred arches, but the same term is applied to the use of scaffold-boards to support concrete floors while they are setting hard. (*See* CARPENTRY.)

CENTERVILLE, a city of south central Iowa, U.S., 88 mi. S.E. of Des Moines; county seat of Appanoose county, served by the Burlington, the Rock Island and the Southern Iowa (freight; electric) railways. The altitude is 1,013 ft. Pop. (1950) 7,606. Large quantities of coal are mined in the vicinity. Quarrying of limestone, stock raising and dairying, ironworks, a soybean mill and creameries are among the industries. In 1846 the town was platted as Chaldea, later called Senterville and finally changed to Centerville by the legislature. It was chartered as a city in 1870. The town was, at one time, an important ferry terminal for the Chariton river.

A junior college was established there in 1930 and provides normal school training and liberal arts courses; a football stadium and a large park near the centre of the city provide recreational facilities.

CENTERVILLE, a town in southwestern Pennsylvania, U.S. It is situated in Washington county about 26 mi. S. of Pittsburgh and about 5 mi. W. of the Monongahela river, on federal highway 40.

The altitude is 1,160 ft. Pop. (1950) 5,874; (1940) 6,317 by the federal census.



The town derives its chief income from farming and mining. It is administered by a mayor-council government. The town, which is incorporated, was laid out as a pike town in 1821 although the first settlers established themselves within the borough as early as 1766. Its name derived from its relative position between Washington and Uniontown.

The deep narrow valley of the near-by Monongahela river is the most conspicuous topographical feature in the rolling, hilly country which comprises Washington county. The area is one of the earliest to be explored west of the Allegheny mountains and it is rich in historical sites.

The earliest settlers in the region were chiefly of Scotch-Irish and German descent, coming there from eastern Pennsylvania, Virginia and Maryland.

CENTIGRADE SCALE: *see* THERMOMETRY.

CENTIME. The one-hundredth part of a franc, the monetary unit of France, Belgium, and Switzerland, is termed a *centime*. It is from Lat. *centum*, hundred. In Italy the hundredth part of the *lira* is called a *centesimo;* in Spain the hundredth part of the *peseta* is called a *centimo.*

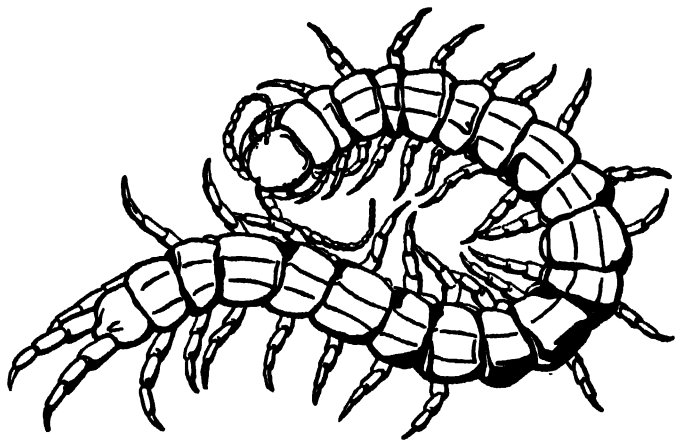
FIG. 1.—A TYPICAL MEMBER OF THE GEOPHILOMORPHA (ORYA BARBARICA), ONE OF THE LUMINOUS CENTIPEDES

CENTIPEDE, an animal with a distinct head, one pair of feelers (antennae) and a long segmented body, each typical segment of which is provided with a single pair of walking legs. The centipedes form in the phylum Arthropoda (*q.v.*), the distinct class Chilopoda in which well defined subdivisions may be made as follows:—

First subclass Epimorpha, in which the young leave the egg with the full number of body segments and walking legs.



This subclass comprises two orders:

(*i.*) Geophilomorpha (contain-

ing ten families) with *Geophilus* as the typical genus, and

(*ii.*) Scolopendromorpha (containing two families), *Scolopendra* being the typical genus.

Second subclass Anamorpha, in which the young leave the egg with seven pairs of legs. Afterward there are periods of growth each of which is followed by a change of skin, resulting in an in-

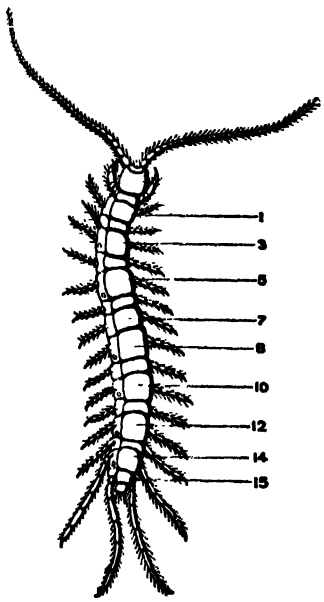
FIG. 2.—SCOLOPENDRA MORSITANS A TYPICAL MEMBER OF THE SCOLOPENDROMORPHA

crease in the number of pairs of limbs until the adult condition is reached. In this subclass, also, there are two orders:—

(*i.*) Lithobiomorpha (containing three families). *Lithobius* is the typical genus, and

(*ii.*) Scutigeromorpha (consisting of one family), with the genus *Scutigera* as type.

The head of the centipede (*see* fig. 6) bears a pair of many-jointed antennae. Three pairs of mouth appendages are present, the mandibles, first maxillae and second maxillae. Right and left first maxillae are fused to form a kind of lower lip to the mouth. The second maxillae, which lie behind the first, are but slightly modified walking legs, in which some of the constituent leg segments are still easily recognizable. But though their bases meet in the mid-line, the second maxillae do not form a lower lip to the mouth, for this is formed by the first maxillae. There is therefore nothing comparable with the labium of insects.



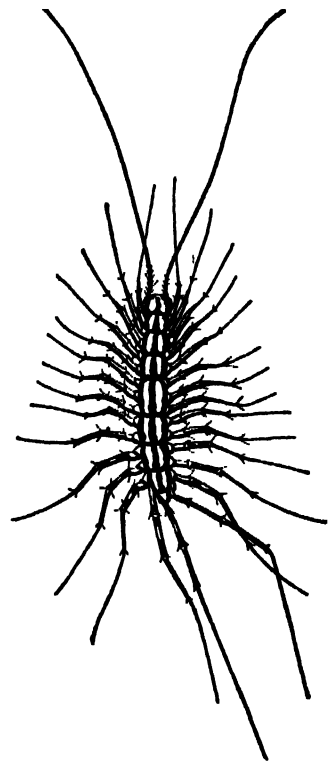


FIG. 3.—A TYPICAL MEMBER OF THE LITHOBIOMORPHA, THE COMMON CENTIPEDE OF EUROPEAN FIELDS AND GARDENS

The head, body and limbs are invested with cuticle which remains flexible wherever movement of the parts is necessary, and elsewhere is thickened by a deposition of horny chitin. In a typical limb-bearing segment consisting of a roof, a floor and side walls, the cuticle covering these is reinforced to form definite protecting and supporting plates or sclerites, differently arranged in different forms. Except at the joints the cuticle of the limbs is similarly hardened.

The last three segments of the body (called pregenital, genital and anal segments) are without walking legs.

Eyes occur in most Lithobiomorpha, all Scutigeromorpha and in all Scolopendromorpha except one family (Cryptopidae). They are absent in Geophilomorpha. A simple eye (ocellus) or a group of separate ocelli is usual but in Scutigeromorpha the external lenses of the group of units fuse into a single faceted lens.

On each side of the head in *Lithobius* a sense organ (organ of Tömösvary) of unknown function occurs; it consists of a group of cells below the chitin associated with an external hollow near the antenna. The frontal organ of *Lithobius* and *Scolopendra* consists of a group of deep-seated nerve cells behind each eye—its use is unknown.

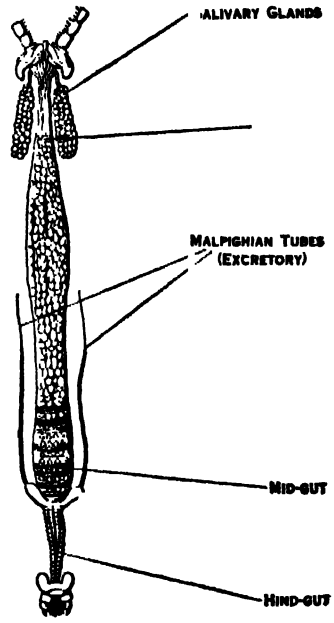
FIG. 4.—A TYPICAL MEMBER OF THE SCUTIGEROMORPHA (SCUTIGERA), THE HOUSE CENTIPEDE



The digestive tube is simple; it receives, in front, the products of the salivary glands and, further back, those of the excretory (Malpighian) tubules. Its opening is in the anal segment.

The main nerve cord lies below the gut and ends in front in a nerve mass (the suboesophageal ganglion) united with the supra-oesophageal ganglion or "brain," which lies above the front of the gut, by a pair of stout nerve cords.

Breathing is by air tubes or tracheae which open at the sides of the body except in the Scutigeromorpha in which the openings are in the middle line of the back.

The heart, which lies above the gut, is a simple tube and the blood circulation is in the direction usual in invertebrates—forward dorsally and backward ventrally.

The reproductive system, which lies above the gut, varies in different centipedes. In the male the number of testes ranges from 1 to 24. In the adult female the ovary is always unpaired. The reproductive system opens in the genital segment.

AFTER VERHOEFF, IN BRONN, "KLASSEN UND ORDNUNGEN DES TIER-REICHS" (WINTER)

FIG. 5.—DIGESTIVE TRACT OF A CENTIPEDE (LITHOBIUS FORFICATUS)

Owing to the retiring habits of centipedes comparatively little is known about their reproduction. Although the satisfactory observation of copulation has never been recorded, on anatomical grounds it is believed to take place. In the Anamorpha the female after laying each egg carries it about between the specialized claws at the hinder end of her body and eventually, when it has been smeared with a secretion or earth, or both, lays it down where its covering is sufficient protection against enemies.

The eggs of Epimorpha are laid in an open nest and the female guards them faithfully until hatching takes place.

The egg is rich in yolk; this serves as food for the developing centipede which grows from a special area in the lower part of the egg. An examination of the developing animal when the process has been some time in progress may reveal the beginnings of the various head segments and of the walking limbs. When the animal at length leaves the egg its form varies as already indicated, according to the order to which it belongs.

Centipedes as a class have a world-wide distribution. Fossil centipedes occur in amber of Oligocene age but all older remains tentatively referred to the class Chilopoda are problematical

Many Geophilomorpha have the power to give light, but as these animals are blind the property is perhaps accidental. The light is produced by the simultaneous discharge upon the lower surface of the body of two kinds of glands, which occur in the floor of the body segments. When the two fluids mix outside the body a light is produced.

When the gardener hunting for slugs at night sees *Lithobius* carrying off a small slug and shaking it as a terrier shakes a rat he rightly assumes that the centipede is his friend; but *Lithobius* may kill and eat beneficial insects as well. Geophilomorpha are certainly carnivorous at times, but one species (*Haplophilus subterraneus*) has been known to damage growing celery, lettuce and onions, and other species are likely to be similarly injurious at times.

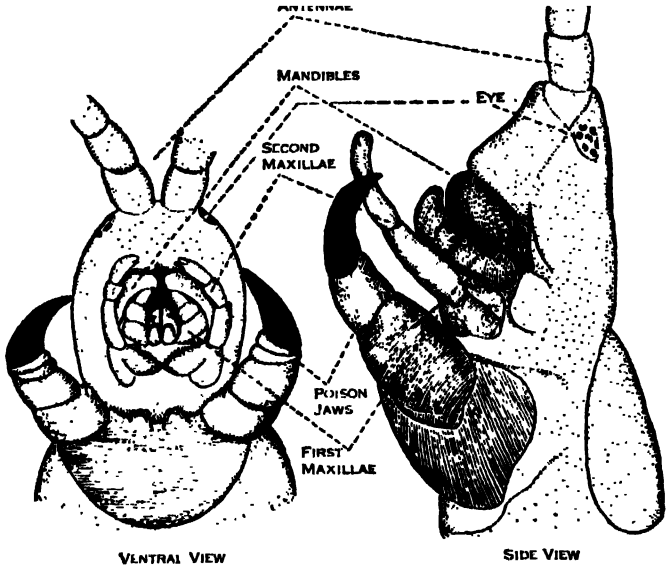


FIG. 6.—HEAD OF CENTIPEDE (SCOLOPENDRA)

The painful bite of large centipedes may on occasion cause danger to life. "The part bitten should be bathed in a solution of ammonia—about 1 in 5" (Hirst). Pseudoparasitism in man may be due to accidental invasion of the ear or nasal passages and adjacent sinuses by Chilopoda; or to swallowing them either accidentally or in a state of impaired mentality.

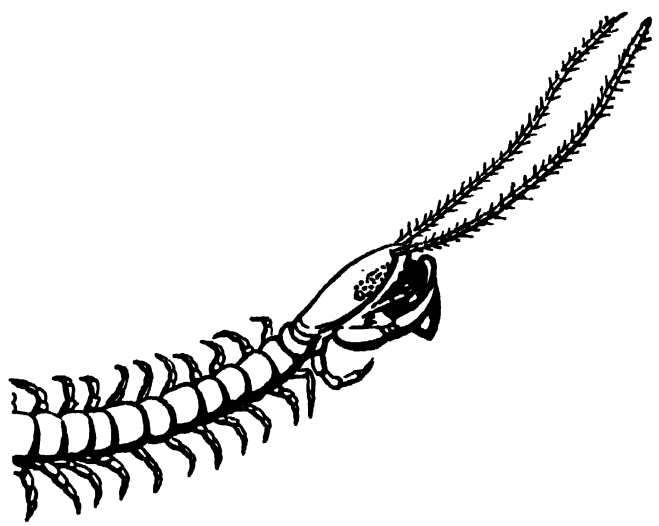

FIG. 7.—LITHOBIUS EATING A SLUG

Brief mention of centipedes is made by early writers (Aristotle, Pliny, Aelian). Oviedo, the companion of Columbus, describes the occurrence of centipedes in the island of Santo Domingo, where he was supervisor of gold smeltings, and mentions the bright light emitted by some of them.

The literature in English is very scattered—most of the best modern accounts are in German.

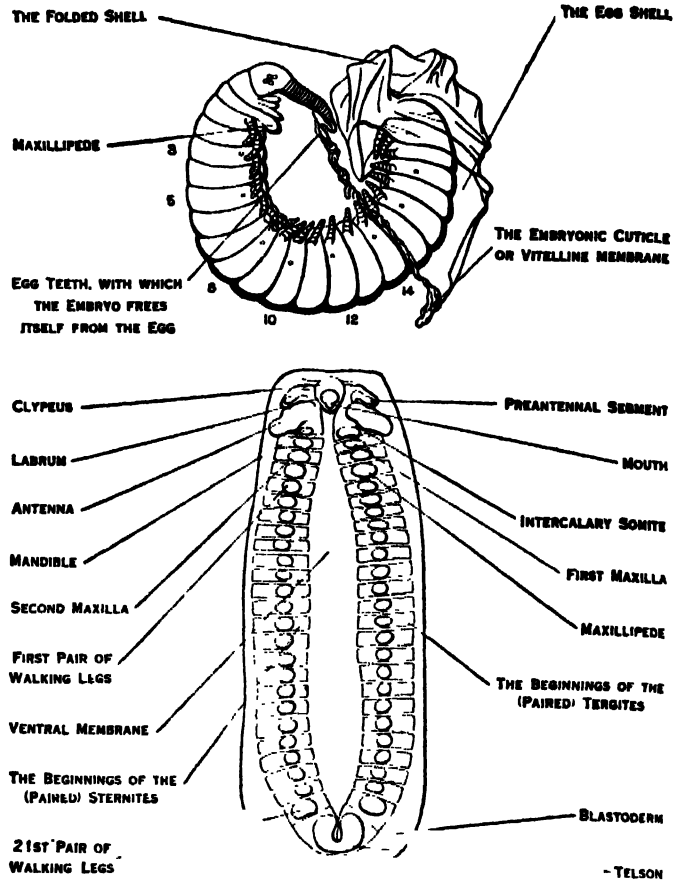

FIG. 8.—DEVELOPMENT OF A CENTIPEDE (SCOLOPENDRA CINGULATA) Above, the embryo in the act of leaving the egg. The front part of the egg shell is already removed, and the back part thrown into folds. The embryonic cuticle is still attached to the end of the antennae. The numbers indicate leg-bearing somites. Below, developing embryo

CENTLIVRE, SUSANNA (*c.* 1667–1723), English dramatic writer and actress, married at 16 the nephew of Sir Stephen Fox, and on his death within a year she married an officer named Carroll, who was killed in a duel. Left in poverty, she began to support herself by writing for the stage. Some of her early plays are signed S. Carroll. In 1706 she married Joseph Centlivre, chief cook to Queen Anne, who survived her. Her first play was a tragedy, *The Perjured Husband* (1700), and she herself appeared for the first time at Bath in her comedy *Love at a Venture* (1706). Among her most successful comedies are: *The Gamester* (1705); *The Busy Body* (1709); *A Bold Stroke for a Wife* (1718); *The Basset-table* (1706); and *The Wonder! a Woman keeps a Secret* (1714), in which, as the jealous husband, Garrick found one of his best parts. Her plots, verging on the farcical, were always ingenious and amusing, and the dialogue fluent. She never seems to have acted in London, but she was a friend of Rowe, Farquhar and Steele. Mrs. Centlivre died on Dec. 1, 1723. Her dramatic works were published, with a biography, in 1761 (reprinted 1872).

BIBLIOGRAPHY.—W. J. Jerrold, *Five Queer Women* (1929).

CENTO, a town of Emilia, Italy, province of Ferrara, 18 mi. S.E. direct from the town of Ferrara, 50 ft. above sea level; it is reached by road (6 mi. to the west) from the station of S. Pietro in Casale, 15 mi. S.W. by W. of Ferrara, and also by a steam tramway (18 mi. N.) from Bologna to Pieve di Cento, on the opposite bank of the Reno. Pop. (1936) 5,677 (town); 22,371 (commune). It was the birthplace of the painter Giovanni Francesco Barbieri (Guercino).

CENTO, a composition made up by collecting passages from various works. The Byzantine Greeks manufactured several out of the poems of Homer, among which may be mentioned the life of Christ by the famous empress Eudoxia, and a version of the biblical history of Eden and the Fall. The Romans of the later empire and the monks of the middle ages were fond of constructing poems out of the verse of Virgil. Such were the *Cento Nuptialis* of Ausonius, the sketch of biblical history which was compiled in the 4th century by Proba Falconia, wife of a Roman proconsul, and the hymns in honour of St. Quirinus taken from Virgil and Horace by Metellus, a monk of Tegernsee, in the latter half of the 12th century. Specimens may be found in the work of Aldus Manutius (Venice, 1504; Frankfurt, 1541, 1544). In 1535 Laelius Capitulus produced from Virgil an attack upon the dissolute lives of the monks; in 1536 there appeared at Venice a *Petrarca Spirituale;* and in 1634 Alexander Ross (a Scotsman and one of the chaplains of Charles I) published a *Virgilius Evangelizans, seu Historia Domini nostri Jesu Christi Virgilianis verbis et versibus descripta.*

CENTRAL AMERICA, the major isthmus lying between North America and South America and extending from the Isthmus of Tehuantepec, in Mexico, through the Isthmus of Panamá to Colombia. This geographical region includes the Mexican states of Yucatán, Campeche, Tabasco and Chiapas and the territory of Quintana Roo; the republics of Guatemala, Honduras, El Salvador, Nicaragua, Costa Rica and Panamá; and the crown colony of British Honduras, which is claimed also by Guatemala and is known to Spanish-speaking peoples as Belize. The approximate over-all extent of Central America is thus from 7° to 21° 30′ N. lat. and from 77° (due south of Washington, D.C.) to 94° (due south of Beaumont, Tex.) W. long., or roughly 1,150 statute mi. east and west by 1,000 mi. north and south. The total area is approximately 300,000 sq.mi. and the population is more than 11,-100,000 (1950 census figures and reliable estimates), of which 0,487 sq.mi. and 2,339,030 inhabitants are in the five abovementioned Mexican states and territory.

Central America trends mainly northwest and southeast, as seen in its southwestern margin, the gently sinuous and occasionally indented Pacific coast line, roughly paralleling the volcano-studded mountain backbone, which is visible from the shore at most points. The eastern and northern coasts border the Gulf of Mexico and the Caribbean sea and are characterized by more extensive lowlands and lower mountains than the Pacific side; also by long, straight steplike north-south and east-west segments in the northern portion. The low-lying Yucatán peninsula extends northward, from the flat Guatemalan Petén department and British Honduras, as a major anomaly in the isthmus, and presents the principal barrier separating the Gulf of Mexico from the Caribbean sea. Only the narrow Yucatán channel between the northeastern tip of the peninsula (Cape Catoche) and the western tip of Cuba connects these two mediterranean bodies of water.

The term "Middle America" is sometimes used as a synonym for Central America, but more often regional geographers include all of Mexico, Central America and the West Indies in Middle America as distinguished from North America and South America.

Because of their history of former political unity and sporadic efforts at restoring a union, the countries of the early 19th-century Central American federation (Guatemala, Honduras, El Salvador, Nicaragua and Costa Rica) are frequently referred to as the Five Republics of Central America. Not until the beginning of the 20th century (1903) did Panamá begin its independent political life, as it formerly was a narrow, isthmian extension of western Colombia.

Certain physical, historical and cultural similarities lend validity to the regional concept of Central America, most of which was geologically related, was occupied by the ancient Maya Indians and was embraced in the Spanish colonial *audiencia,* or judicial district, of Guatemala.

GEOLOGY AND PHYSIOGRAPHY

Central America geologically is one of the most complex regions in the world, and much of it is little known. In many ways it resembles an enormous island, being in reality a double peninsula, since it is attached at both ends: in Mexico, at the Tehuantepec constriction, and in Panamá, where it joins South America. Many of its peculiar characteristics may be explained by this peninsular nature. Northwestern Central America probably was insular during parts of the Palaeozoic era, and was linked to the Greater Antilles, though separated from North and South America by narrow straits.

The oldest-known geologic formations in the area are Palaeozoic, usually designated as pre-Permian, since no rocks of proved age older than Permian have been found. Most so-called Carboniferous rocks are of early and middle Permian age, and Pre-Cambrian or Archaean formations may be no older than middle Palaeozoic.

The original nuclear core of Central America, typified by granite and metamorphic sedimentary rocks, embraces parts of the present political areas of Chiapas, Guatemala, Honduras, British Honduras and Nicaragua. The date of this ancient formation is uncertain, but it was probably Pre-Cambrian. Sections of the primordial nucleus, which trend in great east-west arcs (the Antillean or Caribbean mountain system, as distinguished from the Andean system), have been continuously above the sea since early geological time, and the region appears to have been originally a westward continuation of the Greater Antilles (Cuba, Jamaica, Haiti and Puerto Rico). It was broken apart and the West Indian segment separated into islands by faulting during various periods of geologic history, especially in late Cenozoic (Pliocene-Pleistocene). Probably there was a westward extension of the core land of Central America to Baja California in Cretaceous time. Marginal to the old nucleus on the north, a large area sank, starting in the middle Jurassic period, as the Gulf of Mexico began to form. Later deposits (mostly Pliocene and Quaternary) were re-uplifted as the nonfolded marine mantle formations of Tabasco, Campeche and Yucatán, in Mexican Central America, and the contiguous states of Oaxaca and Veracruz, continuing across the Isthmus of Tehuantepec into the main region of Mexico. Ranges of younger volcanoes, striking essentially northwest-southeast, overlie and largely bury the east-west basement Antillean mountains.

Southeast of the nuclear, ancient Central American land mass lies a distinct geologic region, including present-day Panamá, Costa Rica and southern Nicaragua. Largely of volcanic origin, the narrow Costa Rica-Panamá isthmus, barely 40 mi. wide at the Panama Canal, is geologically recent, having emerged as land only in the middle Miocene period. Then a great submarine ridge was arched up more than 12,000 ft. above the ocean floor, and from the late Miocene through the Pleistocene period intrusive mountains were uplifted upon the crest of the ridge, from western Panamá to southern Nicaragua, terminating in a period of intense and explosive volcanic activity. It was through the eruptions of volcanoes that the great ridge was built up above sea level. Though the Panamá isthmus has the east-west striking S-curve typical of the Antillean system, the trend becomes more nearly northwest-southeast as western Panamá near the Costa Rican border merges with the Pacific volcanic ranges.

Marine Portals and Land Bridges.—Previously, except for a brief land-bridge period from late Cretaceous to middle Eocene, a wide portal had been open through the Panamá-Costa Rica area, with intermingling of Atlantic and Pacific waters. Easterly winds probably forced some movement of water from the Caribbean into the Pacific as a part of the North Equatorial current; hence, it is unlikely that any Gulf stream existed. Brazilian land reptiles, though related to those of Africa and India, were quite distinct from those of North America. Marine molluscs, horn corals, echinids, decapods and sea pens migrated through the portal from the Pacific to the Caribbean. Marine faunas on the two coasts of Central America are closely related as a result of the Panamá and (Pliocene) Tehuantepec portals.

The end of the middle Miocene period saw the beginning of the narrow Panamá land bridge which has continued to the present time. Interchange of marine waters, flora and fauna ceased when the portal closed, and intermigration of animals and plants, interrupted since the Eocene period, was resumed, first between South America and Central America-West Indies, then (Pliocene to

present), after the closing of the Tehauntepec portal, between South America and North America. Several orders of mammals, including some marsupials and primates, probably crossed the Cretaceous Eocene land bridge from North America to South America, and four orders definitely crossed the later Pliocene-Pleistocene bridge. These included the carnivores (*e.g.*, dog, cat), proboscideans (*e.g.*, mastodon), artiodactyls (*e.g.*, deer, pig) and perissodactyls (*e.g.*, tapir).

The Tehuantepec portal was also important in Central American geologic history, having been open during upper Miocene and lower Pliocene and possibly during Eocene times. These past interoceanic straits gave Central America its insular state in middle geologic ages and are reflected today in the narrow isthmuses at either end, which now give the region its peninsular character. Changes in climates as well as in fauna and flora must have resulted from these revolutionary geologic events.

The three narrowest lowland sections of the isthmus, Tehuantepec, the lakes of Nicaragua, and Panamá, were long considered for various canal projects before the Panama Canal was constructed (1904–14).

NORTHWESTERN CENTRAL AMERICA

Highlands.—Surface rock formations in the Central American highlands include widespread marine sediments, especially beds of shales, limestones, sandstones and conglomerates. Many of these were laid down during Permian and Cretaceous ages, and, though fossils occur, the record is incomplete, in part because fossil collections are inadequate. In northwestern Central America these deposits largely cover the ancient crystalline core, and in turn they are overlain, especially near the Pacific coast, by extensive and often immensely deep younger volcanic materials.

Ancient Mountains of Nuclear Central America.—The principal mountains of the oldest periods of folding and faulting, which were late Permian and an undetermined age prior to that, include the Sierra Madre of southern Chiapas, striking northwest-southeast; the Sierra de Chuacús and Sierra de las Minas of south central Guatemala, the former striking almost east-west, the latter east-northeast and west-southwest; and the Sierra de la Grita, del Espiritu Santo and de Omoa in Honduras, roughly parallel in strike with Chuacús, just across the international boundary and beyond the Río Motagua in Guatemala. These folded mountains of ancient crystalline and sedimentary rocks form a nearly symmetrical shallow crescentic arc that is convex to the south. A northern outlier is seen in the core of the Cockscomb horst (up-faulted block) mountains of south central British Honduras, the highest point of which is more than 3,600 ft. In the middle highland region of Guatemala, which is the type area for nuclear Central America, the landscape is characteristically one of steep relief, with deep parallel valleys between high ridges (summits mostly between 8,000 and 10,000 ft.) having sharply dissected flanks where streams flow through barrancas (gullies and canyons).

Other ancient mountains having pre-Permian granites, gneisses and schists and east-west strike are to be seen in Honduras, especially the northern third, and in northern Nicaragua. The mountains are separated into short, steep and rugged ranges with fault basins in between, and though there is little order in the intricately dissected highlands, a northern and a somewhat higher southern system of cordilleras may be discerned. The highest point is 9,400 ft., in the Cerros de Celaque, but most of the many summits are under 8,000 ft. Honduras as a whole is the most mountainous country of Central America, having extremely narrow and limited coastal and interior plains. The highlands of northwestern, interior Nicaragua are similar in height and ruggedness to those of Honduras, though of undetermined age.

Highlands of Middle and Recent Geologic Time.—Except for the most recent and currently active volcanoes along the Pacific side, which have buried the older strata to the north and east, the highlands of northwestern Central America were uplifted to their present high elevations during Mesozoic and Cenozoic (especially Pliocene), "mediaeval" and "recent" geologic time, respectively.

The plateau of San Cristobal, or Mesa Central, in Chiapas consists of nearly horizontal Cretaceous beds which were enormously up-faulted during the Pliocene period, and it towers above the Río Grijalva valley. Contiguous with this highland, across the border in west central Guatemala, the Altos Cuchumatanes horst stands as one of the most impressive nonvolcanic mountain areas in the whole region. The east-west southward-facing front of this great limestone block rises to a high point of more than 13,000 ft., higher than all the great volcanoes to the south except Tajumulco (13,814 ft.). It presents a nearly straight 40-mi. east-west wall more than 10,000 ft. in elevation above sea level and with relief heights above the Río Negro from 3,000 to 5,000 ft. This is the dominant single relief block in all the highlands of Central America. The lofty summits are smoothly rolling, with sinkholes characteristic of karst topography in limestone areas, but around the margins of the massif profound canyons drop away to breath-taking depths. Following the crescentic arc farther eastward through the Alta Verapaz, the Pliocene orogeny is manifested in other features of step and block faulting, mostly minor as to relief except for the hill lands south of the Cockscomb mountains of British Honduras. This is the same great faulting series that separated Cuba from Yucatán and broke apart the islands of the Greater Antilles.

Major Structural Depressions.—Enormous troughs caused by faulting and folding are prominent relief features in northern Central America, notably the central depression of Chiapas, a great graben (down-faulted block) through which flows the Río Grijalva and where the capital city, Tuxtla Gutiérrez, is situated. This depression lies between and parallel to the Sierra Madre and the Mesa Central. The east-flowing Río Negro and the west-flowing Salegua of Guatemala follow structural valleys having the great scarp of the Cuchumatanes as a north wall. The Motagua and Polochic rivers drain northeastward and eastward through deep, ancient furrows, ultimately reaching the Caribbean. Lago de Izabal (Golfo Dulce) lies at the foot of the Polochic valley. The great Honduras depression, or Plain of Comayagua, is a graben, but its strike is anomalous in that it trends north-south, transverse to the Antillean mountain structure. More than 40 mi. long and having widths up to 15 mi., this trough is one of the major fault zones of Central America and is continued northward by the Río Humuya valley and southward by the Goascoran. Many of the rivers of southern Honduras flow through deep box canyons cut in lava beds, and this incision by drainage accentuates structural lines.

Recent Volcanoes.—The most prominent and striking feature of the mountains of Central America is the file of conical peaks, nearly all of them recent volcanoes, at or near the Pacific from Tacana, on the southern Mexico-Guatemala border, to Chiriquí, an outlier just across the Costa Rican boundary in Panamá. Only in southeastern Costa Rica and Panamá is the volcanic chain widely broken. These volcanoes, more than 100 large and 150 minor ones in all, trend in overlapping arcs, roughly northwest-southeast. They are geologically young (possibly pre-Miocene in places, definitely Pliocene to Recent) and form a mantle resting upon the older east-west ranges which they cross diagonally. The older volcanic lavas and ash beds, some of them having great thickness, form a broader base upon which the recently and presently active volcanoes rest.

Two distinct series of volcanic mountains, trending in gentle minor convex arcs toward the Pacific, may be traced as follows: one from Chiapas through Guatemala and El Salvador, and another through Nicaragua and Costa Rica into Panamá. Each series has a length of approximately 350 mi. (excluding Chiriquí because of its isolation from the others), with the two merging in the region of the Gulf of Fonseca.

The northwestern or Guatemalan (as distinguished from Costa Rican) series is the larger and more important, with a base of volcanic deposits extending the full length of the zone, from about 40 mi. N.W. of Tacana volcano, an average of 40 mi. wide in the western portion and 60 mi. in the eastern, where it covers nearly all of El Salvador. In Chiapas and Guatemala the crest of the older volcanic mantle forms the continental divide, with the recent volcanoes to the southwest and parallel with it and, roughly, with

the Pacific coast. The numerous short, steep streams flowing to the Pacific follow antecedent courses, resulting in enormous gaps between the volcanoes and deep dissection of the loose volcanic detritus. Some cones are simple and well formed, as Tacana and Tajumulco (the highest peak in Central America, 13,814 ft.) at the western extremity of the Guatemalan group, and other smaller ones at the east. The central volcanoes tend to have multiple peaks, such as Santiaguito-Santa María, Atitlán-Tolimán and Fuego-Acatenango. In all such cases the coastward vent is the younger, the first-named of each of the above pairs. Fuego has been intermittently active for centuries, Santiaguito only for a few years but with rapid, continued growth. The blocking of openings by lava, especially andesitic, which is highly viscous and hardens rapidly, causes lateral explosions and the birth of new basal cones, as was the case with Santa María in 1902. Most of the western Guatemalan lava and ash is light-coloured andesitic, becoming darker and more basaltic toward El Salvador.

Consequently, in the latter border zone, wide fields of dark lava with lower, shield-type volcanoes present a markedly different landscape from the towering cones of the west. Izalco, in El Salvador, has been one of the most active vents in Central America during its short life.

Extensive deposits of volcanic ash, mostly light buff-coloured, from earlier eruptions, filled a number of highland valleys near the headwaters of streams, forming highly fertile basins that have had a long history of intensive settlement and cultivation. One of the most noteworthy of these is the basin of Quezaltenango, second city of Guatemala, situated in the upper Samalá basin at an elevation of nearly 8,000 ft. From San Juan Ostuncalco to Totonicapán this nearly level, open bolson is more than 22 mi. long.

Volcanism has disturbed the drainage with resultant formation of a number of lakes, some of them spectacularly beautiful, such as Atitlán, in a collapse basin (*caldera*) that is partly volcano dammed, and Amatitlán, wholly dammed, in Guatemala; and Coatepeque, Ilopango and others in volcanic depressions in El Salvador.

Earthquakes.—A broad Pacific belt, southeastward to Panamá, is subject to frequent and violent seismic activity characteristic of such highly unstable volcanic areas, some earthquakes being caused by eruptive activity, others by faulting. A number of cities have thus been destroyed, notably Antigua Guatemala in 1773 and modern Guatemala city in 1917–18. Ash eruptions may cover wide areas, as spectacularly illustrated by the tremendous explosion of Coseguina (Nicaragua), which spread ash dust more than 500 mi.

Lowlands.—The gently sloping Pacific coastal plain, attaining a maximum width of about 35 mi., is composed mostly of Quaternary volcanic alluvium, reflecting in its sharply convex curve toward the Pacific the great volume of ejecta which has been blown from the vents, then much of it carried westward by the easterly trade winds and reworked by streams. In El Salvador and Nicaragua the coastal plain narrows.

By far the most extensive lowlands of Central America are to be found in the extreme north. The great plain of the Petén, in Guatemala, at the base of the predominantly limestone peninsula of Yucatán, is almost all less than 1,000 ft. in elevation. The Mesozoic and Cenozoic sedimentary beds are largely horizontal. The descent to these northern lowlands is by steps as a result of block faulting along the strike during the Pliocene period. The marine beds of Tabasco, Campeche, Yucatán and Quintana Roo, as in northern British Honduras and the Petén, are so low and horizontal that there is little stream development—almost none on the outer peninsula. The Usumacinta, the only large river, is marginal to the Petén, at the foot of the Chiapas highlands. Sinkholes (*cenotes*) are numerous, the result of limestone solution, in a karst area, and it is here that water is obtained by the inhabitants, who must also depend upon windmills and catchment basins. Swamps and marshes are extensive, especially in Tabasco. Large beds of little-weathered sea shells attest to the recency of the emergence of this area. The deposits themselves are of Cenozoic age, Eocene through Pleistocene. The present width of the peninsula dates to late Pleistocene uplift, and the straight coastal lines are fault features, the largest being the east coast of the peninsula, more than 400 mi. long. Late Pleistocene subsidences along the north and west coasts of the Yucatán peninsula have caused certain marine invasions, most notable of which is the Laguna de Terminos in Campeche.

The second largest lowland plain of northern Central America is that of eastern Honduras (essentially the disputed area, claimed also by Nicaragua) and the eastern portion of Nicaragua, almost half the area of the older, northern province, about 100 mi. wide in the area of the upper Tuma river. Most of the larger rivers of Nicaragua and Honduras cross this lowland, notably the Coco, along the disputed Honduras border, and the Patuca, in the disputed zone. The igneous basement rocks of the lowlands are covered mostly by undisturbed, nearly horizontal marine Pleistocene beds and Recent alluvial deposits. In places, granites are exposed. Except for these two large lowland areas, and a few limited river valleys, this coastal plain of Nicaragua, Honduras and El Salvador is extremely narrow.

SOUTHEASTERN CENTRAL AMERICA

The distinct geologic province of southeastern Central America includes the long, narrow, S-shaped Isthmus of Panamá and Costa Rica and the low Nicaraguan lakes trough and coastal volcanic range. The present land bridge between North and South America is of geologically recent origin (late Miocene). Prior to the formation of the isthmus, a large, deep marine portal had been open, from Eocene to late Miocene, permitting free circulation of water between the Atlantic and Pacific oceans. The flow was mostly westward, under the influence of easterly winds that drive the North Equatorial current. The isthmus at the narrowest point, near the Panama Canal, is about 40 mi. wide, and at the widest part, at the Nicoya peninsula, it is more than 150 mi. wide. The growth of this connecting link was by volcanic action, mainly in Eocene time, forming a ridge upon an elongated submarine arch. Basaltic and especially andesitic volcanic materials are overlain by early Cenozoic marine beds. Intrusive mountains were uplifted in upper Miocene-Pliocene, and through later Pliocene and Pleistocene were further built up by numerous highly active volcanoes of the explosive type. Chiriquí, at 11,410 ft. elevation, stands atop the isthmian ridge about 24,000 ft. above the ocean floor on either side.

Panamá.—The topography of Panamá is irregular and broken, more hilly lowland than mountainous, with most of its area under 1,500 ft. elevation. The highest points, a number of them over 7,000 ft., are in the west, along the igneous Serranía de Tabasará, and culminating in Chiriquí volcano. The lower Serranía del Darién forms the eastern backbone along the Caribbean. Though primarily volcanic, some sedimentaries, especially limestones, shales and sandstones of the early Cenozoic, prior to the Miocene and later uplifts, cover the igneous rocks. This is best seen in the east, near the Colombian border. The limited Tertiary marine beds of Panamá are thinner and less folded than those of Costa Rica. Folding parallels the coast and often is asymmetric, with steeper slopes toward the Caribbean, especially notable in Darién. A number of north-south thrust faults cut across central Panamá and seemingly have locally affected relief and drainage. There is no longer any active volcanism in Panamá.

Costa Rica.—The Costa Rican highlands extend from southeast to northwest, the full length of the country, in a diagonal trend that brings them nearer the Pacific side, especially in the north. Three distinct, contiguous cordilleras, having roughly parallel strikes but different arc trends and a central break in continuity, may readily be traced: the Cordillera de Guanacaste, or Volcanic range, in the northwest, with six major volcanoes between 4,500 and 6,200 ft. high; the Cordillera Central, just north of the centre and with nearly east-west strike and four large volcanoes, the highest being intermittently active Turrialba at 12,300 ft.; and the Cordillera de Talamanca, the largest and highest of the three ranges, which is continued in Panamá to a point near Chiriqui volcano. Between the latter two chains, and near the convergence of the three, is the sedimentary Candelaria highland, the economic,

cultural and political as well as the approximate geographical centre of Costa Rica. San José, the capital city, has a favourable situation there that in many ways is parallel to that of Guatemala city. Both are near the continental divide, are just under 4,000 and 5,000 ft. elevation, respectively, in highlands near volcanoes, nearer the Pacific coast than the Atlantic and served by coast-to-coast rail connections. From the Candelaria divide two major rivers flow in opposite directions—the Río Grande de Pirris, west-southwestward to the Pacific at the Gulf of Nicoya, and the Reventazón, northeastward to the Caribbean sea. The railroad follows these valleys, with terminals at the ports of Limón on the Caribbean and Puntarenas on the Pacific.

The highest point in Costa Rica is not a volcano. It is Cerro Chirripó Grande, 12,588 ft., summit of a large area of the Talamanca range almost 10,000 ft. in elevation, the only Costa Rican area of its size having such elevation. It is almost comparable in elevation and extent with the Cuchumatanes highlands in Guatemala, and it has even greater relief height (7,000 ft. in four miles).

Great transverse ridges extending coastward in both directions from Chirripó Grande serve as effective barriers to movement along the Pacific and Caribbean lowlands. The Pacific flanking ridge merges with a coast range that parallels the southern third of the Costa Rican Pacific plain, and between it and the Talamanca range is the General highland. These two elevated areas are made up of deep-seated crystalline rocks, both light and dark types, and were formed by thrust faulting. The Caribbean coastal lowlands are much wider than the Pacific lowlands and continue into Nicaragua, across the San Juan valley and in the lowland lakes (Managua and Nicaragua) trough. The Pacific coastal lowland is limited to a very few miles in width except at the bases of the large peninsulas of Nicoya, Osa and Burica. There is much swampland along the lower river valleys of both coasts.

Nicaragua.—The southwest Nicaraguan coastal volcanoes form a continuation of the Costa Rican Volcanic range and belong geologically to the Costa Rican mountain arc, which meets the Guatemalan arc somewhere near the Gulf of Fonseca. At present-day San Juan plain, the wide lowland gap between the highlands of Costa Rica and Nicaragua, there was an ocean portal open between late Oligocene and middle Miocene times, judging from marine deposits and especially West Indian type *Orbitoides* fossils found west of Lake Nicaragua. Late Miocene-Pliocene elevation of a narrow isthmus across the present San Juan valley resulted in the formation of a large embayment, in place of the present lakes region, extending from the Gulf of Fonseca to the Gulf of Papagayo, with the ancient Nicaraguan highlands forming the Pacific bay shore line. This narrow east-coastal land bridge was eroded by streams flowing away toward the Pacific and Caribbean from the low continental divide. At the same time (Oligocene-early Miocene) the line of volcanoes of Nicaragua began to form, and, with their renewed activity in Recent time, continuing to the present, they built up a nearly straight barrier, which broadened as the volcanoes grew and ultimately filled in most of the bay, leaving lakes Managua and Nicaragua (the latter more than 100 mi. by 40 mi.) as the only remnant water surfaces, now fresh. Three volcanic cones arose on two islands above the surface of Lake Nicaragua, and one in Lake Managua, with four others bordering it, including active Momotombo. The drainage divide shifted to the Pacific range, and the lake waters freshened and began to flow the long way out to the Caribbean through the San Juan river. This low trough cutting diagonally across Nicaragua is the locus of most of the economic, cultural and political life of the country, with the capital city, Managua, and Granada situated in the interlakes area, and the second city, León, just off on the Pacific coastal margin. Great interest has been shown in this low trough, most of it under 350 ft. elevation, as the site of a projected interocean canal. It was seriously considered for the crossing before the Panama Canal was built, and, afterward, as an alternate route.

CLIMATES AND WEATHER TYPES

Temperatures.—Locally, throughout Central America, as in certain other parts of tropical Latin America, climates are usually classified into three simple vertical groups: *tierra caliente*, hot land; *tierra templada*, temperate land; and *tierra fria*, or cold land. This corresponds with and probably stems from the old division of the earth into torrid, temperate and frigid zones dating back to the ancient Greeks. It is difficult to fix any limits to these "climates," which are altitudinally conditioned thermal zones. The "hot land" is, of course, the lowest in elevation above sea level. Citing western Guatemala as a typical illustration, this is approximately from 26° C. (78.8° F.) mean annual temperature at sea level to 22° C. (71.6° F.) at 1,000 m. (about 3,280 ft.) above mean sea level. The temperate belt extends upward from this point to about 1,900 m. (6,233 ft.), where the annual temperature is normally about 17° C. (62.6° F.). Above that, in the upper mountains and valleys, is the "cold land," culminating with about 5° C. (41° F.) at the summit of Tajumulco volcano (13,814 ft. or 4,211 m.), the highest point in Central America. Temperatures, hence also altitudinal zone lines, are slightly higher in the countries to the southeast. Any temperature limits can be set arbitrarily, but for world comparisons the Köppen "tropical" and "mesothermal" (temperate) types, with the coldest months warmer and cooler, respectively, than 18° C. (64.4° F.), are valid in Central America. The Köppen tropical-mesothermal isotherm (equal-temperature line) follows about the 1,450-m. (4,756-ft.) isohyps or contour line, which is just in the centre of the "temperate" zone of local usage.

By far the greater part of Central America has tropical climatic conditions, the terminal isthmuses, the narrow Pacific coastal lowlands and the broader Gulf and Caribbean coastal plains, as well as the entire Yucatán peninsula into the Petén of Guatemala, all being warm to hot the year around. Cooler, temperate conditions are limited to the higher mountain and intermountain basin and plateau areas.

Rainfall.—Rainfall, which has far greater seasonal variability than temperature, is not taken into account in the local climate classification. It is, however, the basis for the seasonal distinctions, "summer" being the dry season, with its clear skies, warm sun and pleasant weather, and "winter" being the more dismal rainy season, when cloudy skies actually may reduce daytime temperature maxima to points below those of summer. It must be borne in mind that local summer is climatologically winter, for the sun during that season (November through April) is highest south of the equator most of the time. Conversely, local winter is climatological summer, the rainy season, May through October, with maxima in June and September. This seasonal rainfall regime is characteristic of the Pacific lowlands south to Panamá, the Isthmus of Tehuantepec and most of the Yucatán peninsula, which have the Köppen tropical savanna climate. Highland regions nearer the Pacific coast, as in Chiapas, southwestern Guatemala and El Salvador, have the cooler phase of the summer-rain, winter-dry type. Toward the southeast the dry season is shorter, as the total annual rainfall for the region as a whole tends to increase. San José, Costa Rica, has five months of dry season (December-April), and Balboa, Canal Zone, has only three months, January to March inclusive, as compared with the six dry months of similarly situated stations in northwestern Central America.

The Pacific coast is in general drier than opposite points on the Caribbean, from British Honduras southeastward. East coastal Nicaragua is especially rainy, Greytown (San Juan del Norte) having recorded an annual average of more than 260 in. Similarly, highlands toward the Carribean side have rainfall distributed more evenly through the year, as seen as far interior as the Alta Verapaz (Cobán area) of Guatemala. Rainfall is concentrated along windward sides of mountain ranges, especially along the coastal volcanic chains. The southern Guatemala coffee belt is delimited by this, and the premium grades depend upon the cooler highland temperatures. Annual precipitation there ranges between 400 and 550 cm. (160 and 220 in.), according to exposure, in altitudes between 700 and 1,400 m. (about 2,300 and 4,600 ft.). The dry season is also reduced there, to three or four months (December-March). Deep valleys are generally much drier than adjacent highland areas. This is evident not only in the east-west structural valleys of Guatemala, where rain shadow conditions exist with

respect to both northerly and southerly rain-bearing winds, but also in such north-south troughs as the Honduras depression.

The driest major area in Central America is the low northern tip of the Yucatán peninsula, where Progreso registers 19 in. In the hot tropics, where evaporation is always high, this amount of rainfall usually means almost desert conditions. There it is drier steppe (Köppen). Southeastern Guatemala is perhaps the next largest of the drier areas, though it exhibits less extreme aridity than north Yucatán. The greater rainfall of the north (Caribbean) coasts as compared with the south (Pacific), except for Yucatán, can be seen in comparing the annual rainfall of Colón, at the north end of the Panama Canal, more than 127 in., with Balboa Heights, at the south end of the Panama Canal about 40 mi. away, with 69 in. Colón has two slightly drier months in winter (February-March).

Weather.—Diurnal ranges of temperature generally exceed annual ranges in Central America, as elsewhere in the tropics. In highland Guatemala, for example, daily variations of 15° C. (27° F.) are common in the dry season, while the annual range is less than 5° C. (9° F.). The prevailing winds in most of the region are northeasterly (between east-northeast and north-northeast), characteristic of the northern hemisphere trade winds, especially strong in the winter half-year. "Northers," strong, gusty north winds which may blow for several days, occur in northern Central America, into El Salvador, the effects of anti-cyclonic fronts of cold polar air masses that roll across North America in winter. They bring exceedingly clear skies, even in the afternoon. Because of the narrowness and dominantly marine nature of the isthmus of Central America, land-and-sea breezes are well developed. There, in the tropics, daytime heating of land surfaces, especially in the mountains, is intense, creating low pressure and onshore winds. These oppose the trades and, in the dry months of the Pacific region, result only in cloudiness from mid-morning to shortly after dark. In the rainy season, when the sun is nearly overhead at noon, or is even to the north, the trades are weakened and southerly winds with greater intensity bring rain. Hail is rare, usually coming in March and April in the high northern mountains. At night, as the land cools, especially in the highlands, the land breeze sets in. In winter on the south coast, as it strengthens the trades, the sky is swept clear, usually before midnight except at the height of the rainy season. Then cloudy nights may occur, and continuous rain night and day for several days. Mountain fog above 5,000 or 6,000 ft. is common at such times, as it is in afternoons throughout most of the year. On the north coast, as in Honduras, the northerly sea breeze joins forces with the northeast trades, which are strongest in winter, so that there is actually a winter maximum of rainfall in certain sections (La Ceiba to Puerto Castilla, for example). Rain throughout most of Central America comes usually in the form of intense tropical thunderstorms, from late morning to evening in normal rainy-season weather or at any time of day during *temporales*, or stormy wet spells. At such times relative humidity is constantly high. Hurricanes occasionally strike the northern Caribbean coast, from late July to early October. Belize especially has suffered the effects of these outer-tropical storms, and great destruction has been caused by them in the banana area around Puerto Barrios, Guatemala, but away from these coasts the effects of such storms is slight.

NATURAL VEGETATION AND SOILS

Because of the great range of climatic and edaphic conditions and the crossroads situation of the isthmus, the flora of Central America is extraordinarily diversified, containing thousands of species of many types of plants. Furthermore, the natural vegetation has been much altered by cultivation. For these reasons, it is extremely difficult to generalize regarding the vegetative cover. Certain broad generalizations may be made, however.

Tropical Rain Forest.—The most extensive single vegetation type is that of the tropical rain forest, found mostly near north and east coasts and slopes near these coasts. It consists of tall, spreading broad-leaved trees, with lower-storied trees underneath and a fairly clear sunless floor where only shade-tolerant herbaceous plants and shrubs can grow. The external aspect of these forests is similar to that of other rain forests of the world, as in the Amazon and Congo valleys and in parts of the East Indies.

Common among the taller trees are meliaceous (including mahogany), lauraceous and sapotaceous genera, *Ceiba, Ficus* and many others, and among the lower plants, *Inga, Carica, Cecropia,* palms and tree ferns. Great serpentine climbing vines and slender, rubbery hanging ones, such epiphytes as orchids and bromeliads, and long-leaf ferns add to the luxuriance of this forest. In vines as in trees, textures range from very soft to very hard. One fleshy vine contains potable water for those who recognize it. The numerous species of trees tend to be scattered, rather than occurring in pure stands as they do in the less benign high-latitude climates. Thus, in lumbering for mahogany or balsa, or tapping the latex for rubber or chicle, each tree must be sought out individually in the forest. This is lonely, difficult and costly work.

Though soils, except for alluvial bottom lands, tend to be only of superficial fertility, with shallow humus leaf mould underlain by leached and sometimes cemented subsoils, these forest areas are often cleared for agriculture even by primitive natives. They kill trees by girdling, cutting only through the cambium layer of dicotyledonous types and burning the dead trunks. Much of the lighter, regrown rain forest, especially in the old Maya area of the Yucatán peninsula, has been affected thus by human occupancy.

Great areas of rain forest have been cleared for plantation agriculture, primarily for bananas, secondarily for coffee, cacao, abacá and other crops. Corn, beans and such annual staples will grow throughout the year. This clearing has been most extensive in the rain forests of the eastern and northern (Caribbean) coast, in isolated areas from Guatemala to Panamá. There the rain forest reaches its widest extent, covering most of the eastern half of Nicaragua. It narrows along the north coast of Honduras, broadening again across the base of the Yucatán peninsula, into Campeche and westward through Tabasco, to the Isthmus of Tehuantepec. Along the middle slopes of the Pacific coastal highlands, mainly between 3,000 and 4,500 ft., as in the coffee belt of Guatemala, a monsoon forest that resembles a rain forest occurs, but with the tree ferns and epiphytic luxuriance of the cloud forest.

Park-Savanna, Deciduous Woodland and Gallery Forests.—Almost the entire Pacific lowland is characterized by open park land, with deciduous trees interspersed by tall savanna grasses and sedges, except where gallery forests border the innumerable streams. Scattered out over the more open interstream areas are occasional giant trees such as the ceibas, with wide, spreading crowns high above the ground, and many smaller trees which become seared and brown or even bare during the long, dusty dry season (generally November through April). Because of the open, grassy patches and drier climate, this coast has been especially important for cattle raising since shortly after the conquest. With the onset of the rains in April and May, the landscape becomes green and bright with flowers, and corn, beans, cotton, cassava and other crops begin to grow. In moist, marshy areas such broad grasses as calathea abound, and corn can be grown throughout the year, with a crop in three or four months at any season, and with better results than on the excessively wet Caribbean coast.

Mangrove, Outercoastal Swamps.—Groves of giant corozo or cohune palm grow in the outer Pacific lowlands, and fan palms, mangrove (*Rhizophora mangle* especially) and other swamp plants are found along the shore and the brackish lagoons of both the Pacific and the Caribbean. Soils along the outer coast that during the rainy season become impassable clay mires dry with deep, gaping cracks and uneven blocks and may be almost impassable in the dry season as well. The volcanic soils of the upper Pacific coast and piedmont are usually excellent for crops, particularly coffee and rubber.

Cactus, Thornbush, Scrub, Subxerophytic.—Thornbush, cactus and scrubby trees dominate the vegetation of the northern tip of the Yucatán peninsula, corresponding somewhat with the state of that name, where henequen cultivation for fibre is the principal occupation. Eastern Guatemala has similar vegetation,

especially around Zacapa and the deep Río Motagua depression; it continues into El Salvador and covers also other deep interior Guatemalan valleys, the central depression of Chiapas and the Honduras depression. Where drought is extreme, tall cactus forms such as species of *Cereus* and *Opuntia* are dominant; thornbush genera, including acacias and mimosas, and species of *Crescentia*, a scrubby tree useful for its calabash fruit with a receptacle shell, are also found.

Mixed Coniferous-Hardwood Forests.—On most of the mountains and plateaus of middle elevation (4,500–7,500 ft.) of northwestern Central America (Chiapas, Guatemala, Honduras, El Salvador and northern Nicaragua) the forest is mixed coniferous (especially pines) and hardwoods (notably oaks, *Quercus*) and often rather open than dense. This is frequently the result of clearing for agriculture, which is especially important in the major areas of human settlement. Maize has the greatest acreage of crops locally consumed, and coffee among the export products. In the high valleys, where it is somewhat drier, agaves are important for fibre. Exposed seaward slopes between 4,500 and 7,000 ft. in Guatemala and El Salvador are covered in places with cloud forest, most luxuriant growths, wet and green and often covered with epiphytes. There the tree ferns are at their best.

Temperate flora from Nicaragua northward seems to have more elements which originated in North America, whereas south of Nicaragua more can be traced to the Andes of northern South America. As in geology, the major dividing line is Nicaragua-Costa Rica. South of Nicaragua, too, the pines diminish in importance, but oaks are well represented in the Costa Rican highlands.

Alpine Bunch Grass, Conifers, Meadows.—In the highest mountain areas, above about 8,000 ft., coarse, giant bunch grass, somewhat larger than the common types of the Andean altiplanos of northern South America, is common. In highland Guatemala it is widely used for roof thatch. Cypress trees, junipers and pines grow on the higher ridges and summits, often in almost pure stands at elevations above about 10,000 ft. There also, where summits are smooth and rolling as on the high Cuchumatanes, alpine meadows of short grasses and low flowering plants of many colours are typical. Sheep raising is the principal occupation, as it is too high for most agriculture, even wheat and potatoes. Besides the cold, which excludes some crops, the deep surface layers of raw humus, in places approaching peat, are unfavourable to cultivation. Mountain fogs are frequent during the day, but it is less rainy than at lower elevations.

ARCHAEOLOGY AND HISTORY

PRECONQUEST PERIOD

Northwestern Central America: Maya.—In the extreme northwestern part of Central America, especially Guatemala, Chiapas, British Honduras and the northern Yucatán peninsula, one of the most elaborate Indian civilizations of the American continents flourished for centuries before the arrival of the Spanish conquerors. This was the Maya civilization, whose extraordinary sculptures on stone, made without metal tools, and whose high attainments in mathematics, astronomy, the domestication and development of many important cultivated plants, including varieties of corn and beans, attest to their outstanding advancements in arts and sciences. For their religion and social organization they were likewise remarkable. They invented a vertical enumeration by position and a calendar more accurate than that used in the world today.

The story of the Maya and their contemporary eastern neighbours (in the present-day Honduras-Guatemala border zone) of different linguistic stock, the Chorotega, can be pieced together from archaeological remains preserving their writings in stone. The hieroglyphs have been little deciphered except for dates. Prior "archaic" cultures are obscure, but it is evident from their remains, buried under great ash and lava deposits, that they were basket and pottery makers for an undetermined period through centuries far antedating the Christian era. At Uaxactun archaeologists have discovered a sequence which shows that the Maya civilization, with its elaborate architecture and brilliant ceramic art and sculpture, developed from the "archaic" pottery makers.

The Maya pushed the Chorotega northward into Chiapas, Mexico, and southeastward into the Pacific coastal areas of El Salvador, Honduras, Nicaragua and Costa Rica early in the Christian era. The ultimate origin of the new world Indian populations is, in the opinion of most anthropologists and archaeologists, western Asia. From there they migrated into the new world via the Bering straits during periods when geologic and climatic factors made this feasible. The Maya civilization represents one of the major accomplishments of the descendants of these immigrants. There is reason to believe that there were close connections between the Maya of Petén and Chiapas and groups occupying the Isthmus of Tehuantepec. It was expected that research and excavation being conducted in that region would clarify whether this was the ancestral home of the Maya or whether it was occupied by a closely allied civilization. Maya tradition held only that they came from Tula, in eastern Mexico.

As builders of great stone temples, probably indicative of large centres of population but not necessarily so (dwelling sites have rarely left recognizable traces), the Maya started in the central part of their later territory, in the Petén and Chiapas regions, along and near the great water highway the Río Usumacinta. The population there today is the sparsest in all Central America, and the great temples of Tikal, Uaxactun, Yaxchilán and Palenque were buried under a covering of rain forest, virtually forgotten by the outside world until near the middle of the 19th century. Their classic period began there about the beginning of the 4th century A.D., according to most accepted calculations. Somewhere between the 6th and 8th centuries they reached their highest development, having spread southward to Honduras, where Copán still retains their well-preserved works of art, northward into all of Yucatán and westward into most of Chiapas. Between the 8th and 10th centuries, according to their dated monuments, they seem to have declined. This decline is related to the increasing population, impoverishment of farm land and resulting social tensions which were not resolved until what many authorities consider was a major breakdown in the Maya classic period civilization. During the 10th and 11th centuries a renaissance period of Maya civilization occurred along the northern edge of the Yucatán peninsula. This occurred under the political and military influence of the Toltecs, who amalgamated with and changed the ceremonial and religious emphasis of Maya civilization. The great cities of Uxmal, Chichen-Itzá and Mayapán, which became the dominant Mayan league, were the result of the blending of the artistic and sacred aspects of Maya civilization with the military emphasis and secular organization of the Toltecs.

This New Empire, as the renaissance period is usually called, in turn had declined by the 14th century and was decadent when the Spaniards arrived to hasten its final downfall. In the Guatemalan highlands from the 11th century until the Spanish conquest, the Maya also flourished, notably in the principal city-states of the Cakchiquels and Quichés, who were warring among themselves and with their neighbours. There, as in Yucatán and elsewhere, this civil strife worked in favour of the invading Spaniards.

Mexican Influence.—Mexican influence on the Maya, through the Toltecs, culturally, and the later Aztecs, militarily, was marked. This is seen today archaeologically in such features as the ball courts and linguistically in the Pipil (Nahuatl or Aztec) speech among the peoples along the Pacific coastal areas from Chiapas to Panamá. These Pipils are thought to have reached Central America originally as merchants and Aztec mercenaries. They made extended trade voyages for Soconusco cacao, quetzal feathers from the Guatemala highlands, shellfish purple from the Gulf of Nicoya and other special products of Central America which were much in demand in Mexico. The Aztecs borrowed many cultural traits from the Maya, including the calendar and the feathered serpent god (Maya, Kukulcan; Aztec, Quetzalcoatl), which provided some of the best-known motifs for their sculpture. The Maya renaissance bore somewhat the relationship to the Aztecs that the Hellenistic Greek period did to the Romans. Why the Maya declined is not known, but exhaustion of shallow forest soils and encroachment, after forest burnings, by grasses, difficult

to work without the plow and draught animals (both lacking in the new world), must have contributed in large measure.

Archaeologists have differed greatly in their interpretations of Mayan dates. Preliminary evidence from radiation analysis made at the Institute for Nuclear Studies of The University of Chicago seems to support Herbert J. Spinden's dating. His historical outline of the Maya, showing comparative dates, is as shown in Table I.

TABLE I.—*Maya Periods According to Spinden*

Period	Date, A.D.	Date, Maya calendar
Protohistoric period Calendar and hieroglyphic system developed First definitely known date	before 160 47	9-0-0-0-0
Early period Great southern cities began to develop; e.g., Tikal Some of even earlier-style carvings	160–358 214	9-0-0-0-0 to 9-10-0-0-0
Middle period Beautiful works of art of great simplicity	358–455	9-10-0-0-0 to 9-15-0-0-0
Great period Brilliant growth of great cities; *e.g.*, Quiriguá, Yaxchilán, Palenque Great advances in astronomy and architecture Termination caused by civil war, social decay	455–600	
Transition period Shift of emphasis to north, probably central Yucatán Almost no pictorial sculpture	600–960	
Period of Mayapán league Revival of architecture in northern Yucatán League of three cities (Uxmal, Chichen Itzá, Mayapán) and other cities	960–1195	
Period of Mexican influence Toltec supremacy and influence (brief, prior to middle 14th century)	1195–1442	
Modern period Many warring factors Abandonment of cities Itzás founded Tayasal on an island in Lake Petén (site of modern Flores); there preserved Maya culture in isolation until 1696	1442 to present	

Robert Wauchope outlines the sequence of Maya periods as follows: (1) preagricultural; (2) basic agricultural; (3) formative (village and urban forms and protoclassic); (4) classic (early and late); (5) readjustment (Mexican period); (6) militaristic; (7) Spanish conquest. (F. W. McB.; J. B–J.)

Southeastern Central America.—The southeastern limit of Maya-Mexican influence is indefinite, but it seems to be somewhere in southern Nicaragua. The Chorotega reached Costa Rica, as seen in the linguistic island on the Nicoya peninsula, and islands of Nahuatlan speech are scattered through Costa Rica to western Panamá, but these are isolated exotics. In pre-Columbian cultures, as in so many other respects, the Nicaragua-Costa Rica lowlands are at the approximate border zone, which is overlapping and confused. Some monolithic sculptures of the Maya-Mexican type have been found on islands in the large Nicaraguan lakes. Southeastward from north central Costa Rica, Chibchan and other South American ethnological and archaeological elements predominate. Talamancan pottery design techniques from the Costa Rica-Panamá border region resemble those of Colombia, Ecuador and Peru, and the gold huacos, cast and hammered as in Colombia, are almost indistinguishable from Colombian work. Evidences of Pacific coastal trade contacts between southeastern Central American peoples and the Inca of the Peruvian coast were observed by the first Spanish explorers.

SPANISH CONQUEST AND COLONIAL PERIOD

Gold-hunting expeditions of the Spaniards, exploring southward from their base in Santo Domingo, brought them first to the coast of Central America at Panamá, or Darien, as the narrowest portion of the isthmus was called, about the beginning of the 16th century. Alonso de Ojeda may have visited the north coast in 1499, but it is known that Rodrigo de Bastidas sighted the eastern section while scouting from the Gulf of Venezuela in 1501, and Columbus on his fourth voyage, following the coast from Honduras, probably went as far east as Puerto Bello, which he is said to have named. He entered several small bays for shelter, and many historians contend that he was seeking a passage to the orient. His reactions to Indians wearing gold ornaments, especially notable near Veragua, the Spaniards' acquisition of the gold by "barter" and their constant query as to the source of the gold fail to support the "eastern passage" idea. It was hope for gold which led the Spaniards eastward instead of westward from Honduras.

Spanish Penetration From the Southeast.—Spanish settlement on the mainland began on the east coast of the Gulf of Urabá, separating the isthmus from South America, where a short-lived colony was founded in 1509. This gulf became the dividing point between Castilla del Oro (Golden Castille), extending northwestward to Cape Gracias a Dios and including the coasts of modern Nicaragua, Costa Rica and Panamá, and Nueva Andalucia, extending northeastward to Cape de la Vela, being essentially the present coast of Colombia. The regional term which included both these colonies was Tierra Firme (Mainland). The colony was relocated in 1510 at the mouth of the Atrato river, was called Santa María de la Antigua del Darien, the first real settlement and first city (1515) founded by Europeans on the new world mainland, and an important base of exploration and exploitation. It became notorious for its unhealthfulness and fatal fevers, including malaria and yellow fever, but gold dust, trinkets and some pearls came in from the west, and the Spanish push was in that direction. Thus the Pacific, previously well known for pearls, was "discovered" officially by Vasco Nuñez de Balboa in 1513, in the name of the king. Pedro Arias de Avila (better known as Pedrarias Davila), who was sent to replace Balboa and later had him beheaded, united Castilla del Oro and Nueva Andalucia as Castilla Aurifica, extending from Cape de la Vela to Veragua. His search for gold, which occurred in some abundance in Veragua province east of the young volcanic mountains, was characteristically ruthless, and the native Indian inhabitants were almost wiped out within a few years. Many new diseases, brought by the white man, ravaged the Indians there as elsewhere and aided the conquest.

In 1519, the year Hernan Cortes began the conquest of Mexico, Pedrarias founded the city of Panamá (just east of its present site), which attracted most of the inhabitants of Antigua (Urabá colony). The last of those who remained in the older city were massacred by Indians, and in 1524 the town was destroyed and thenceforth abandoned. Panamá grew rapidly and was made a city by royal decree in 1521. The Pacific coast had the advantages of a drier, more healthful climate and relative safety from pirates, who had to march overland from the Caribbean (Francis Drake, Henry Morgan and others later raided Panamá nevertheless). Panamá was the exploration base for the development of Central America from the east, and, even more important, the mandatory gateway to Peru. All the great riches from that wealthy South American colony of Spain had to pass through Panamá. The first Caribbean port for the transisthmian portage that anticipated the Panama Canal was Nombre de Dios, important during most of the 16th century. It had a good harbour and an easy overland route to Panamá, almost due south of it. But it suffered heavily from piracy, gales and diseases, and was a miserable post that teemed with life only when the silver fleets came in. Later in the century, the port of transshipment was shifted a little westward to Puerto Bello, but it became just as bad, though it remained active through the colonial period. Panamá flourished as a great and wealthy city, and in 1753 was made an *audiencia* or seat of colonial Spanish government. Negroes were brought in as pearl divers and slaves to replace the Indians, so that the city became the largest single slave market in Spanish America, and the composition of the population became increasingly black. Here as elsewhere along the drier Pacific coast, cattle became especially important in the open savannahs and woodlands.

Having explored and scratched off the superficial wealth of all Panamá by 1522, Pedrarias moved to greener pastures, this time in Nicaragua, where some scouting had been conducted for sev-

eral years. In this northwestward shift the Spaniards by-passed Costa Rica, attracted by the gold-bearing sands of Nicaragua. Also in the latter country, in the great lakes depression, two large Indian towns, the largest yet encountered, occupied the sites where Managua, on Lake Managua, and Granada, on Lake Nicaragua, later grew. These were outpost settlements of the old Maya-Toltec-Aztec town-builder complex, and as they were far removed from Panamá the Indians were not completely wiped out. The plundering was good, but it had attracted another group of plunderers from the north, men sent out by Cortes from Mexico. These stopped Pedrarias' forces, and civil strife ensued in western Nicaragua. The villa of León was established as a frontier fortress to hold Cortes' men in check. For many years the Gulf of Fonseca region was the scene of much conflict and hatred.

Costa Rica was not settled by Europeans until after the middle of the 16th century, when settlement was begun by Franciscan missionaries, notably those of Talamanca. Lay Spaniards came in gradually, and the theme of settlement was agricultural rather than mineral. During the Spanish colonial period it was one of the spots of thinnest colonization. Cartago, which began as a religious centre, was the chief town until the early 18th century, when this distinction passed to San José.

Spanish Penetration From the Northwest.—Penetration and settlement of Central America from Mexico, in the northwest, was nearly contemporaneous with that from Panamá in the southeast. Pedro de Alvarado, capable lieutenant of Cortes, was sent out from Mexico to undertake the conquest of Guatemala. This was another chapter in the Spanish story of small bands of men who overcame enormous odds by daring and by the elements of terror and surprise injected with the first sight of mounted men with firearms. Strategy, the use of enemy factions as allies, and cruelty, for which Alvarado became almost as well known as Pedrarias, all contributed, as did the new diseases which accompanied and even preceded the Spaniards. There is evidence that influenza was among the pandemic maladies which they introduced to a people with no immunity.

Alvarado crossed the Isthmus of Tehuantepec in 1522, following the Pacific coastal lowlands through Soconusco, Chiapas, famous for cacao, money of the Mayas and Aztecs and drink of the nobility. There were many large towns and colonies of Maya-speaking Indians along the volcanic piedmont. The Pipil, a Nahuatl-speaking group that pushed southeastward from Mexico on trade journeys, especially for cacao, had established small colonies, and Alvarado was accompanied by Aztec mercenaries, who were responsible for the naming of so many places in Guatemala by Mexican names which supplanted the Maya. The major and decisive battle between Spaniards and Guatemalan Indians took place on the highland plain of Quezaltenango, where the pre-Columbian Quiché city of Xelajú was situated. Vastly outnumbered, the Europeans defeated the Quiché-speaking hordes and marched on across the mountains to establish the first capital of Guatemala in 1524.

The Indians were driven mercilessly in a mad and futile search for gold in this land of so much volcanic and limestone cover; but, probably because of relatively inaccessible mountain retreats, many thousands were able to survive. Today their descendants form the largest Indian concentration in Central America and one of those least modified by outside influences. In a larger measure than elsewhere, they were able to resist much of the modification wrought by the Spanish land-grant systems (*repartimiento*), where great tracts and the inhabitants on them were given by the crown to loyal and influential subjects for their personal use and the "protection" of peons; and to withstand also the effects of the church practice of the *reducción*, whereby native peoples were brought from their scattered settlements into compact, nucleated ones more easily controlled by the missions. Lowland and piedmont Guatemala provided the Spaniards with cacao, cochineal, indigo, sarsaparilla and many other valuable products. El Salvador, with its low elevations and extensive tropical climatic areas, was especially important for these items. Consequently, there was great destruction of the Indians, and El Salvador is largely a mestizo country today. These areal terms are used in their modern sense, for in colonial times the captaincy general of Guatemala included all of Central America except Panamá, which exercised jurisdiction over most of the Spanish colonial provinces from Nicaragua through South America.

Honduras, which had been claimed for Spain first by Columbus in 1502, was later the field of activity of Cristobal de Olid, Cortes' captain who was sent by water in 1522 to establish a colony and to block the expansion of Pedrarias. His expedition, which set up its base at Trujillo, was contemporaneous with the overland conquest of Guatemala by Alvarado and was successful in blocking Panamá. But his revolt and treachery made life difficult for Cortes, who was forced to undertake a most arduous punitive expedition. Puerto Cortés, which he founded, still bears his name. Underlain by old crystalline rocks, Honduras was rich in minerals and provided much placer gold. After intensive exploitation, especially about the middle of the 16th century, this was largely exhausted. Honduras had five villas during most of the 16th century, more than any of the present Central American republics (Guatemala had one). These were Trujillo, Gracias a Dios, Comayagua, the old capital, and the important gold camps of Olancho and Naca. Many Negroes were brought in to work the placers. Cattle raising was of great importance and more lasting then mining.

Chiapas was also of some importance for placer mining, but was especially noted for horses, mules, cattle and other livestock. Like Guatemala in most respects, it was entered and colonized from that country.

Yucatán, which had been a stepping stone in the conquest of Mexico, held no mineral wealth or other attraction for exploitation, and it was not until after 1550 that the Spaniards attempted to colonize it. Unsuited to production of indigo or cochineal, it was at first a cattle region. Mérida, the capital, was a bishop's seat and active missionary base. Sisal, the old port, later gave its name to the fibre, locally called henequen.

As cattle raising was concentrated in the drier regions of the Pacific and northern Yucatán, so forestry yielded greatest returns in the wet tropics. Timber, dyewoods, medicinal products, gums and flavouring extracts were rich products from the rain forests of the base of the Yucatán peninsula along the Caribbean coast to Panamá. The British imported Negroes from Jamaica and other islands in the West Indies to work in the forests, as they had earlier brought in Carib Indians. Both stocks are still prominent along the Caribbean coast, and the Mosquito Indians are more Negroid than Indian. The Lacandon Indians of Petén and Chiapas, last survivors of Maya speech, show strong Negroid traits.

The political fragmentation of the centrifugal, particularistic European colonies and their vassals, physical differentiation of peoples and the locations of towns were largely determined by the end of the colonial period.

PERIOD OF INDEPENDENCE

All of Central America was included in the captaincy general, or military government, of Guatemala during the early colonial period. It formed a part of the viceroyalty of Mexico, then called New Spain, but its captains general reported directly to the Spanish crown. The *real audiencia* (Spanish judicial seat) of Guatemala, established in 1570, did not include Panamá, which had its own *audiencia* (as a part of New Andalucia and, after 1718, the viceroyalty of New Granada), and thenceforth the captaincy general of Guatemala included all of Central America except Panamá.

The colonial province of Guatemala declared its independence from Spain, which in its decadent state was unable to maintain its colonial empire, in 1821, as New Granada had in 1819. Mexico also ended three centuries of Spanish domination and became independent in 1821, after more than ten years of fighting. The short-lived Mexican empire of Agustín de Iturbide assumed jurisdiction over Guatemala, as it then was defined, from 1822 to 1823, when autonomy was returned to the Central American province with the downfall of Iturbide. The Republic of the United States of Central America (or Central American Union) was then formed. This was dissolved in 1839, and the five constituent states of

Guatemala, El Salvador, Honduras, Nicaragua and Costa Rica, which corresponded roughly to colonial departments of the captaincy general of Guatemala, became independent republics. Panamá formed a part of Colombia until 1903. Except for British Honduras, all of Central America is made up of republics or parts of republics. "His Majesty's Settlement in the Bay of Honduras," which owes its origin, in 1638, to its strategic position adjacent to the Spanish Main and to rich forest products, is still a British crown colony, though it is claimed by Guatemala and appears as a dependency on all Guatemalan maps. (*See* CLAYTON-BULWER TREATY.)

Agricultural Revolution.—The colonial economic picture largely prevailed until the great development of coffeegrowing began about the middle of the 19th century and Central America went into the world agricultural export market. This was surprisingly late, in view of the enormous popularity of the European coffeehouses during the 17th and 18th centuries, going back to about 1650 in London. Though the world's supply of coffee had come from Yemen, in Arabia, until the end of the 17th century, the Dutch had sent the plant to Surinam in 1718, Martinique received it in 1720, and Haiti became the world's principal producer during the second half of the 18th century. That it had reached Central America by this time is evident in a casual mention of coffee, in a manuscript dated 1783, as a minor plant in the cacao lands of Soconusco, Chiapas. It was little consumed, however, at that time, and the Spaniards did not have a tradition of large-scale agricultural production for export.

Guatemala, one of the chief Central American producers, did not begin large coffee plantings until between 1855 and 1860, when the south slopes of the Pacific coastal volcanoes, with their deep ash soils and monsoon climate, were found to be ideal. The Chiapas coffee region is in the same type of environment. Costa Rica, with similar natural advantages on a smaller scale in the highlands near San José, started major production about the same time (1850), though it had begun exporting in 1825 and coffee was its chief export crop in 1829. Earliest country to produce for export, by the middle of the 20th century it trailed the top two, with less than one-third the production of Guatemala and of El Salvador, the leader despite a late start (1870). German settlers pioneered coffeegrowing in Guatemala, Chiapas and El Salvador, as did the English in Costa Rica. Nicaraguan coffee production is usually about equal to that of Costa Rica, but the other republics are minor producers.

The quality of coffee is an expression of elevation, the highest grade coming from the highest land. In Guatemala it is even officially graded by the altitude of the plantation on which it grows, the upper limit being nearly 6,000 ft. An aristocratic economic and social system grew up with the plantation, especially in Guatemala. Cacao, cochineal and indigo, formerly grown in small plots, were almost entirely replaced there by coffee, based on large landholdings. In El Salvador, a mestizo country with few Indians, the plantations were smaller, with indigo maintaining a considerable importance, and there was less concentration of wealth within a population minority.

Central America and Colombia produce a large percentage of the world's high-grade blending coffee, which must be grown at fairly high altitude, under taller shade trees, with the ground carefully cleared.

Bananas were next in the 19th-century development of plantation agriculture. Though some types of this fruit were known in Central America before the Spaniards arrived, the banana of commerce is reported to have originated in India and to have reached Santo Domingo, West Indies, via the Canary Islands, in 1519. The chief banana-producing countries at mid-20th century were Honduras, Panamá, Guatemala and Costa Rica. Nicaragua's production was cut seriously by the Panamá disease (banana wilt), which was a special hazard in the Caribbean rain forest region.

Late in the 19th century, Yucatán began to develop its important binder-twine industry based on large-scale production of sisal, or henequen, fibre. This was an outgrowth of the needs of the small-grain industry in the United States for twine to tie up the harvested shocks. A highly aristocratic system developed in the state of Yucatán, in the dry, northern portion of the peninsula, which came to provide half the world supply of this twine.

In the rain forest areas of the base of the Yucatán peninsula, especially the Petén department of Guatemala, the tapping of chicle became important as the chief supply of chewing gum, exported mainly to the United States.

ECONOMIC PATTERNS AND FUNCTIONS OF CENTRAL AMERICA

AGRICULTURE

The economy of Central America, like that of most of the American tropics, is based almost exclusively upon agriculture, as pointed out above. Production of food crops for local consumption and of export crops for foreign markets employs the vast majority of the region's labour force and accounts for almost all the foreign trade. In the early 1950s more than three-fourths of the gainfully employed population worked in agriculture, and more than 90% of the exports from the various countries were made up of agricultural commodities.

This basic economy, however, is not uniform either in structure or in function. There is considerable variation in agricultural techniques, in crops produced, in the disposal of these crops and in numerous other facets of production. A simple breakdown of the over-all agricultural economy reveals at least two broad types. These are subsistence food crop tillage and commercial agriculture characterized by export crops such as coffee and bananas.

Subsistence Tillage.—Subsistence crop tillage is for the most part a carry-over from the preconquest period. Its principal products are corn, beans, potatoes, rice and other food crops which are the staples of the local diet. Production is concentrated upon small farms (generally less than ten acres) or upon labourers' provision grounds on large estates. The crops are largely consumed by the farm family, and if there is a surplus it is sold in the markets of near-by towns.

In terms of total land under cultivation, the number of people affected and the bulk of agricultural production, this type of agriculture is probably the most important in Central America. It is the mainstay of the small landholder and the landless tenant and is particularly important in areas such as southwest Guatemala, the lake region of Nicaragua, central Costa Rica, El Salvador and eastern Panamá where rural population densities are high. Since subsistence tillage is of little significance in the export economy of the region, however, the tendency has been to relegate it to a position of less importance than commercial farming.

Commercial Agriculture.—In turn, commercial agriculture may be divided into two types: one developed and controlled largely by local interests and another by foreign interests. The former type is the basic commercial economy of the local populace. Its traditional and by far its most important crop is coffee. However, efforts to improve and diversify agriculture gave emphasis to other export crops such as cane sugar, cotton, sesame and henequen. In addition, food crops for domestic consumption, such as corn, wheat and fruits, are also characteristic of many of the coffee farms, locally called *fincas*.

Ownership within this domestic commercial economy is for the most part in the hands of well-to-do native families. With the possible exception of Guatemala, foreign investment in the coffee economy has been relatively small. In Guatemala prior to World War II, Germans owned or controlled from 30% to 40% of the country's coffee plantations. In 1942, however, the government took these plantations over, and they were placed under the administration of the Central Bank of Guatemala.

Production within this type of agriculture hinges upon the hacienda system, with large, privately owned farms worked by a labour force of Indians and mestizos. In Guatemala, for example, 80% of the 1950 coffee crop was produced on 1,500 large farms employing 426,000 labourers. Because of the climatic requirements of coffee and associated crops, this type of economy tends to concentrate on the lower slopes of the tropical highlands. The portion of this zone, popularly called the *tierra templada*, that

is best for coffee lies approximately between 3,000 and 6,000 ft. above sea level.

The commercial plantation economy developed by foreign capital in Central America is largely a phenomenon of the banana industry. From a meagre beginning in the 1870s, U.S. capital and initiative, led by the United Fruit company, developed a vast economic structure with investments running into hundreds of millions of dollars. The enterprise called for acquiring and clearing thousands of acres of thinly occupied jungle lowlands; the construction of roads, wharves and other transportation facilities; the purchase of a vast fleet of ships; the improvement of sanitation and numerous other undertakings. Reports indicate that by the middle of the 20th century the United Fruit company alone owned almost 400,000 ac. of land, operated or owned more than 1,000 mi. of railways and had millions of dollars tied up in buildings, equipment, livestock and other property in the region.

At first the banana plantations were located primarily on the more humid Caribbean coast. The attacks of the Panamá disease, hurricane damage and other obstacles, however, necessitated a large-scale shift (starting about 1935) to the less humid Pacific coastal area, where production must depend upon irrigation, often from overhead, as at Tiquisate, Guatemala. Much of the land on the Caribbean side which no longer produced bananas was put to producing cacao, palm oil, abacá (Manila hemp) and other cash crops.

To the commercial agriculture associated with bananas the countries of Central America have contributed the land and part of the labour. In turn, they have received such benefits as improved sanitation and transportation, the construction of schools, the clearance of large tracts of jungle lowlands and considerable income from taxes. In most respects, however, this commercial agriculture is little more than a foreign enterprise lightly grafted to the economic framework of the region. It must be kept in mind that the capital, the administrative and technical skills, the machinery and the markets are all foreign and, consequently, the lion's share of the profits also goes to foreign investors.

SUBSIDIARY ECONOMIC ACTIVITIES

In addition to the basic agricultural economy, there are a number of subsidiary occupations which play roles of varying importance within the economic structure of Central America. Chief among these are grazing, mining, lumbering and manufacturing.

Compared with coffee and bananas, grazing is a relatively old economy in Central America. It dates back to the early colonial period, and in terms of land utilization, quality of stock and disposal of products it has changed little through the years. Primary emphasis has been on cattle of unimproved breed, low in beef yields and quality but high in resistance to ticks and other environmental handicaps of the region. Stock raising has always been concentrated on the less humid Pacific savannah lands, but some stock raising is to be found in all sectors. Feeding is almost exclusively on the range or natural pasture basis, and markets are generally local. Honduras, Nicaragua and Panamá have developed a significant export trade in cattle with neighbouring countries, but, because of the scarcity of meat-processing facilities, cattle are driven or transported to markets on the hoof. Efforts were being made to improve both the meat and dairy industries by importing high-bred animals from the United States in the period following World War II.

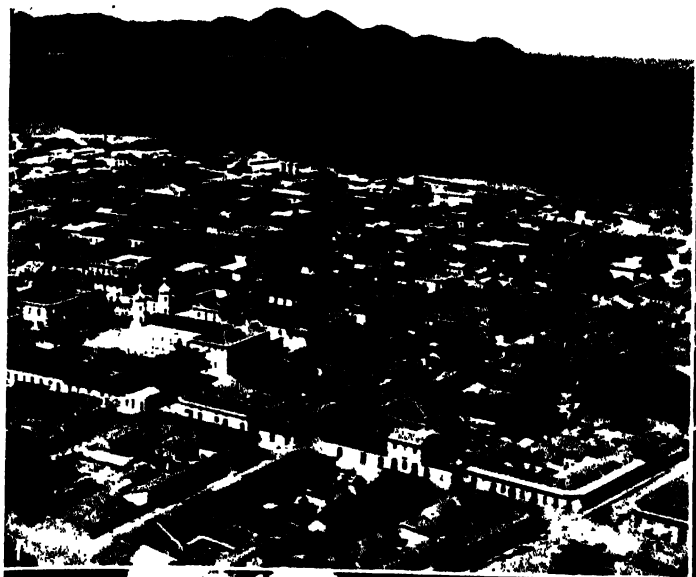
Mining dates back to the conquistadors, but, unlike Mexico, Central America has achieved only small importance in this activity. Gold and silver have been and still are by far the most important minerals produced in the region. These metals figure among the exports of all the political units but are of particular significance only in Honduras and Nicaragua, where old crystalline rocks are less covered by later sedimentary and volcanic beds. Numerous other minerals such as copper, iron, nickel and mercury have been discovered. Exploitation of these minerals is limited, however, because of difficulties of transportation and lack of capital and machinery.

Lumbering, like mining, also figures in the economy of the entire region. In spite of this, the forest resources have been only slightly developed. Primitive logging methods, poor transportation and other obstacles have kept the extensive tropical hardwood forests in practically virgin state. Mahogany is the chief export, but other tropical woods such as balsam, brazilwood, rosewood and ebony are of some significance. Lumbering has been developed on both the Caribbean and Pacific sides of the region, but the more luxuriant forests of the Caribbean have been more extensively exploited. In British Honduras lumbering surpasses even agriculture in importance.

Manufacturing industries, although showing a tendency to increase since World War II, are still small-scale and undeveloped. Lack of capital and skilled labour and poor transportation have limited manufacturing to the processing of certain agricultural products and the production of a few consumer goods for the local market, such as beverages, shoes, soap, ceramics, matches, cement and cigarettes. Many of the manufactures are still in the primitive handicraft stage, and all are associated with small plants, a small number of workmen, limited capital and total reliance upon the local market. Only in a few places, as in the Indian region of western Guatemala, has a significant tourist trade in weaving and other handicrafts been developed.

COMMERCE

The commerce of Central America shows two outstanding characteristics: first, export goods made up primarily of unfinished raw materials and imports of finished goods; and, second, a strong reliance upon the United States both as a source of imports and market for exports, representing usually more than two-thirds in each case. The commerce of the region showed considerable increase in the years following World War II, with an annual average of about $450,000,000, of which roughly 60% represented imports and 40% exports. For the region as a whole the chief items of export are bananas, coffee, gold, fibres and lumber. The imports lean heavily on textiles, machinery, petroleum products, chemicals and foodstuffs. In addition to the United States, other countries that figure significantly in Central American trade are Canada, Great Britain, Mexico and the Netherlands Antilles (Curaçao.)



FOREIGN INVESTMENTS IN CENTRAL AMERICA

Paucity of local capital, the reluctance of native investors to enter new enterprises and the significant exploitable resources of Central America made the region an important focus for foreign investments. Most of the economic development which took place after the latter half of the 19th century had to rely upon foreign capital either directly invested by foreign-owned corporations or loaned to local governments to finance improvements. For example, of the three major railway systems developed in Costa Rica, the Pacific railway (San José to Puntarenas) is owned by the government but was built largely with funds borrowed abroad; the second line (San José to Limón) is owned and operated by the Northern Railway company, a British concern; and the third line serving the Pacific coast is owned by the United Fruit company, a United States concern.

Much of the early foreign capital which entered Central America was British and German. The increasing interest of United States corporations in the region, however, placed the United States far above the British and other foreign investors. The Germans largely lost out as a result of World War II. In the early 1950s United States capital represented usually between 75% and 100% of all foreign investments in all the units of Central America except British Honduras.

Foreign investment in the region has concentrated primarily upon commercial agriculture, public utilities, transportation and, to a lesser degree, mining and lumbering. For example, of the more than $110,000,000 of foreign capital invested in Guatemala in 1948, it is estimated that 95% was in agriculture, public utilities and transportation. Approximately the same percentage applied to Costa Rica and Honduras.

Among the outstanding foreign corporations with heavy investments in Central America are the United Fruit company, the International Railways of Central America, the American and Foreign

Power company, the New York and Honduras Rosario Mining company and the Northern Railway company. Private individuals with direct investments or with government bonds represent various nationalities, but chief among them are Americans, British and French. In addition to corporations and private individuals, some capital for improvement has been made available to local governments by private banks, particularly those of the United States.

There has been a considerable change in policy on the part of Central American governments toward foreign investment. The "free hand" which foreign capital was given in the late 19th and early 20th centuries has been sharply regulated. As a result, further large-scale influx of foreign capital is being discouraged. The economy of the region continues to be plagued by problems stemming from political instability and a thick crust of traditionalism and from frictions inherent in a society sharply divided by race, class and culture.

COMMUNICATIONS

Transcontinental railroads cross the Isthmus of Tehuantepec, eastern Guatemala, central Costa Rica and Panamá (Canal Zone). A standard-gauge line in Mexico meets a narrow-gauge at the Guatemala border on the Pacific coast, and the Guatemalan line (International Railways of Central America) has a branch to El Salvador from Zacapa. Otherwise, railroads are short and limited to individual countries, connecting parts of more populous areas and crop lands, as banana plantations. Honduras has no rail connection between Tegucigalpa, the capital, and the coast. Roads and highways, though covering more of the countries than railroads, are still limited and inadequate. Only major roads are paved, as a rule, and these are narrow. Extensive areas are thinly populated because of rain forest or unhealthful conditions or rough terrain. Though this limits the demand for roads, the building of transportation lines would tend to fill in the population of many sections.

The Pan-American highway, long under construction, was by the mid-1950s still incomplete. Though Mexico had finished its part to the Guatemalan border, it reached this point in the highlands where the Guatemala section had to cross the immense Cuchumatanes mountains in order to connect. There was a gap of 25 mi. An alternate route crossed Guatemala from Tapachula, Mex., to El Salvador, which had paved all but 21 mi. of all-weather road to the Honduras border. El Salvador has one of the best highway systems in Central America. Honduras had completed its part of the highway, unpaved, but all-weather. Tegucigalpa, the only capital not on the route, was connected by an all-weather road. The Nicaraguan segment was complete and more than half paved, the rest all-weather. In Costa Rica, the first 79 mi. in from the Nicaraguan border was virtually impassable. A similar stretch in southeastern Costa Rica had yet to be constructed, and the first 18 mi. into Panamá as well. From a point about 38 mi. E. of Panamá city, no road existed to connect the isthmus with South America.

Most of the countries have government-owned telephone and telegraph systems connecting the principal towns.

POPULATION COMPOSITION AND DISTRIBUTION

The major concentrations of population in Central America are in the southwestern highlands of Guatemala, the north coast and interior valleys of Honduras, interior El Salvador, the Nicaraguan Pacific lowlands, the central highlands of Costa Rica and the Pacific lowlands of Panamá, with areas of lesser density along the north coast of Yucatán, the Chiapas depression, central Guatemala, the Pacific piedmont of Chiapas and Guatemala and northeast coastal Nicaragua. The largest single concentration is in southwestern Guatemala, but El Salvador has the highest national density (about 140 per square mile).

More than one-half the total population lives on the narrow Pacific slope, which is probably not more than one-fifth the total land area. This slope is higher and drier and consequently much more healthful. The areas of sparsest population are the low Yucatán peninsula, except for the north coast, and the large interior forests of eastern Honduras and Nicaragua, Costa Rica and Panamá. In these same Caribbean lowland areas, extending up through British Honduras, is most of the Negro population, latest arrivals in Central America by way of the West Indies. These have intermarried with the scattered hunting tribes of Indians who inhabit parts of the same region, notably the Mosquito, Paya and Carib. The Negro-Indian cross is called zambo. The Indians of the Caribbean coast depend upon agriculture in temporary forest clearings, with cassava as their chief staple, and upon hunting and fishing. Negroes provide most of the labour for plantation and shipping operations.

White descendants of the Spanish colonial settlers, with admixtures of other European stocks and usually a heavy infusion of native Indian and some Negro blood, especially in the Caribbean lowlands, make up the principal element of the population of Central America as a whole. There is great variation among the individual countries. Costa Rica has the largest population of pure European stock, mostly Spanish mixed with some English and German, concentrated on the central plateau and the Pacific slopes. There are barely more than 1,000 Indians. More than half the inhabitants of the Caribbean lowlands are Negroes, most of them from the West Indies. El Salvador is a mestizo country, with almost no Indians. The largest Indian populations are in Yucatán, Chiapas and Guatemala. In the latter two areas, these people live mostly in the highlands, where there has been much physical and cultural blending with descendants of the early Spaniards. The distinction between the two groups is cultural rather than physical. A native non-Indian of predominantly European culture traits is called a Ladino, which is usually, though not necessarily, synonymous with mestizo. A person of "pure" Indian blood, by adopting a predominance of traits derived from Europe, may become a Ladino. Latin-American censuses, following the lead set by Mexico in 1930, supplemented racial characteristics by cultural in enumerating the various elements in the population.

TABLE II.—*Political Divisions of Central America**

Country	Area (in sq.mi.)	Population	Capital	Population
Mexico	94,487	2,330,010	...	...
Yucatán	14,868	515,256	Mérida	155,899
Campeche	19,070	121,411	Campeche	31,374
Tabasco	9,782	351,106	Villa Hermosa	33,588
Chiapas	28,729	904,200	Tuxtla Gutiérrez	28,202
Quintana Roo	19,118	26,096	Chetumal	7,247
Central American Republics	190,076	8,674,715	...	...
Guatemala	42,042	2,787,010	Guatemala	204,008
Honduras	43,277	1,368,605	Tegucigalpa	72,385
El Salvador	13,176	1,855,917	San Salvador	161,951
Nicaragua	53,668	1,057,023	Managua	109,352
Costa Rica	19,238	800,875	San José	86,909
Panamá	28,575	805,285	Panamá	127,874
Dependent areas	9,228	119,714	...	...
British Honduras	8,866	66,892†	Belize	21,886‡

†1950 estimate. ‡1046 census.

The highland Guatemala-Chiapas Indians are among the most distinctive and colourful people in the world. They speak about 20 different dialects, most of them of the Maya linguistic stock, showing extraordinary local variations. In dress, economic pursuits and religious customs they are equally varied. Their basic agriculture is highly developed, mostly originating in that of their pre-Columbian ancestors. The ancient Maya developed an important series of domesticated plants, including varieties of maize, the principal staple crop, lima and kidney beans and probably types of squashes, avocados, chilies and many other useful plants. These have been variously borrowed and distributed throughout the world since the conquest. Many old world crops were adopted in turn by the central American natives. Wheat is extensively grown in the higher mountains, but tropical wheat is usually low in gluten. Rice and sugar, coffee and bananas and many temperate fruits and vegetables have filled important economic roles among low and middle altitude exotics.

The sheep of the highlands, the cattle of the drier areas—in fact, all livestock except turkeys and Muscovy ducks—came to Central America from the old world.

The Indians commonly specialize to a marked degree, both in agricultural products and in supplementary handicrafts. Of the latter, weaving is outstanding, having been developed to a high point of technical perfection, artistic beauty and originality. One specialty, that of fashioning and decorating tree-calabash receptacles, is limited to a single locality in Guatemala.

Such specialization has inevitably led to a vigorous development of local and intersectional trade and teeming weekly markets, economic nerve centres that have never-ending colour and variety, both as to products and their human vendors and consumers.

Religious festivals, combining a veneer of Roman Catholicism over an impenetrable substratum of pagan rites, likewise stimulate periodic fairs, and the combination produces an unspoiled pageantry that is rarely equalled anywhere in the world.

These Indians have no tribal organization nor any cultural differences based upon language. The *municipios*, the smallest civil administrative divisions, similar to townships, are the cultural units, within which

intermarriage (usually by common law) and the rites of religious brotherhoods are practised and costumes, economic pursuits and other cultural traits may be nearly uniform. These tend to differ sharply from one another, even among small adjacent *municipios*, especially those which are isolated by rugged, mountainous terrain, as in the vicinity of Lake Atitlán, Guatemala.

BIBLIOGRAPHY.—*Geology and Physiography:* Charles Schuchert, *Historical Geology of the Antillean-Caribbean Region* (1935), the most comprehensive geological study, includes extensive bibliographies subdivided by regions, of special value in palaeontology and palaeogeography; Oscar Schmieder, *Geografía de América,* Spanish trans. by P. R. Hendrichs Pérez, contains a useful section on Central America with a full bibliography.

Climates and Weather Types: Karl T. Sapper, *Klimakunde von Mittelamerika,* vol. ii, part H, in *Handbuch der Klimatologie,* ed. by Wladimir Köppen and Rudolf Geiger (1932), contains the most complete statistical summary, description, cartographic delineation (small-scale) and bibliography of the climates of Central America; Robert De C. Ward and Charles F. Brooks, *Climates of North America,* vol. ii, part J, sec. 1, *Handbuch der Klimatologie* (1936), contains a chapter on Mexico, including climatological data, descriptions, maps and bibliography for Mexican Central America; F. Webster McBryde, "Studies in Guatemalan Meteorology," *Bulletin of the American Meteorological Society,* in two parts (June and December 1942), contains microclimatological analysis and description, especially of weather and seasons, station data and large-scale climatic map, of a typical area in Pacific Central America.

Natural Vegetation and Soils: Frans Verdoorn (ed.), *Plants and Plant Science in Latin America* (1945), contains an especially wide selection of articles on natural and cultivated plants, vegetation, notes on forestry, conservation, botanical institutions and collections, geology, climatology and soils, with many detailed topical bibliographies; Paul C. Standley, in *Trees and Shrubs of Mexico* (1920-26), *Flora of Costa Rica* (1937-38), *Flora of Guatemala* (with Julian A. Steyermark) (1946–) and other volumes dealing with the flora of most of the countries of Central America, provides the basic references of great bibliographic as well as taxonomic and descriptive value.

Archaeology and History: Preconquest Period: H. J. Spinden, *Ancient Civilizations of Mexico and Central America,* 3rd ed. (1928), is of special value in Maya chronology; among the earlier works of permanent value concerning the Maya and related cultures are T. A. Joyce, *Mexican Archaeology* (1914), *Central American and West Indian Archaeology* (1916) and *Maya and Mexican Art* (1927); *The Maya and Their Neighbors* (A. M. Tozzer memorial volume, by a number of authors) (1940) contains a series of articles on Central American cultures by contemporary specialists, with bibliographies; Sylvanus G. Morley, *The Ancient Maya* (1946), is a comprehensive study of the Maya, with extensive bibliography; J. H. Steward, (ed.), *Handbook of South American Indians,* vol. iv (1948), contains a number of articles on Central American archaeology.

Spanish Conquest and Colonial Period: G. Fernández de Oviedo y Valdés, *Historia general y natural de las Indias* (1851–55), is the earliest full account of the conquest period and is of special value as a basic reference; Bernal Díaz del Castillo, *History of the Conquest of New Spain* (1917), is one of the most important first-hand accounts of the conquest of Mexico; Frans Blom, *Conquest of Yucatan* (1936), excellent on this phase of the conquest, includes a valuable bibliography; Ricardo Fernández Guardia, *History of the Discovery and Conquest of Costa Rica,* Eng. trans. by H. W. Van Dyke (1913), and C. L. G. Anderson, *Old Panama and Castilla del Oro* (1911), cover the conquest of southeastern Central America, the latter with a full bibliography.

Period of Independence: John L. Stephens, *Incidents of Travel in Central America, Chiapas, and Yucatán* (1841), and E. G. Squier, *The States of Central America* (1858), give good accounts of early and middle 19th-century Central America; H. H. Bancroft, *History of Central America* (1883–90), is a comprehensive basic work, of special bibliographic value; Joseph B. Bishop, *The Panama Gateway* (1913), M. W. Williams, *Anglo-American Isthmian Diplomacy 1815–1915* (1916), and Miles P. DuVal, *Cadiz to Cathay: The Story of the Long Struggle for a Waterway Across the American Isthmus* (1940), are three references that deal with the transisthmian transportation problem.

Economic, Demographic and Geographical Publications: Few recent studies deal with Central America as a whole, so it is necessary here to list mainly books on individual countries: Chester L. Jones, *Caribbean Interests of the United States* (1916), D. G. Munro, *The Five Republics of Central America* (1916), and Preston James, *Latin America,* rev. ed. (1950), contain general data and bibliographies. For individual countries, *see* Erna Fergusson, *Guatemala* (1937); Chester L. Jones, *Guatemala, Past and Present* (1940); F. W. McBryde, *Sololá* (1933) and *Cultural and Historical Geography of Southwest Guatemala* (1947), especially for economic and cultural data on modern Indians and ethnobotany of the principal Indian region of Central America; Sol Tax, *Penny Capitalism: A Guatemalan Indian Economy* (1953); W. Vogt, *The Population of El Salvador and Its Natural Resources* (1946); W. S. Stokes, *Honduras: An Area Study in Government* (1950); Chester L. Jones, *Costa Rica and Civilization in the Caribbean* (1935); J. B. Biesanz and M. Biesanz, *Costa Rican Life* (1944); W. Vogt, *The Population of Costa Rica and Its Natural Resources* (1946); W. D. McCain, *The United States and the Republic of Panama* (1937). (F. W. McB.)

CENTRAL AND NORTH AMERICAN LANGUAGES. The population of aboriginal America north of Mexico (about 1,150,000), at the time of the discovery of America by Columbus, spoke an astonishing number of languages, most of which are still spoken, though in many cases by only a bare handful of individuals. Certain of them, like Sioux and Navaho, are still flourishing languages.

They consist of a number of distinct stocks, which differ fundamentally from each other in vocabulary, phonetics and grammatical form. Some of these stocks, such as Algonkin, Siouan and Athabaskan, consist of a large number of distinct languages; others seem to be limited to a small number of languages or dialects or even to a single language. The so-called "Powell classification" of languages north of Mexico recognizes no less than 55 of these "stocks" (*see* the revised map of 1915 issued by the Bureau of American Ethnology), excluding Arawak, a South American stock originally represented in the West Indies and perhaps also on the southwestern coast of Florida.

The distribution of these 55 stocks is uneven; 37 of them are either entirely or largely in territory draining into the Pacific, and 22 of these have a coast line on the Pacific. Only 7 linguistic stocks had an Atlantic coast line. Besides the Pacific coast, in the lower Mississippi and Gulf coast, languages of 10 stocks were spoken (apart from Arawak). The most widely distributed stocks are: *Eskimoan,* which includes Eskimo dialects ranging from east Greenland west to southern Alaska and East Cape, Siberia, as well as the Aleut of Alaska Peninsula and the Aleutian Islands; *Algonkian,* which embraces a large number of languages spoken along the Atlantic coast from eastern Quebec and Cape Breton Island south to the coast of North Carolina, in the interior of Labrador, in the northern part of the drainage of the St. Lawrence, in the country of the three upper Great Lakes and the upper Mississippi, and west into the plains of the Saskatchewan and the upper Missouri; *Iroquoian,* which consists of languages originally spoken in three disconnected areas—the region of Lakes Erie and Ontario and the St. Lawrence, eastern Virginia and North Carolina, and the southern Alleghany country (Cherokee); *Muskogian* (including Natchez), which occupies the Gulf region from the mouth of the Mississippi east into Florida and Georgia and north into Tennessee and Kentucky; *Siouan,* divided into four geographically distinct groups—an eastern group in Virginia and North and South Carolina, a small southern contingent (Biloxi) in southern Mississippi, the main group in the valley of the Missouri (eastern Montana and Saskatchewan southeast through Arkansas), and a colony of the main group (Winnebago) in the region of Green Bay, Wisconsin; *Caddoan,* spoken in the southern Plains (from Nebraska south into Texas and Louisiana) and in an isolated enclave (Arikara) along the Missouri in North and South Dakota; *Shoshonean,* which occupies the greater part of the Great Basin area and contiguous territory in southern California and the southwestern Plains (Texas), also, disconnected from this vast stretch, three mesas in the Pueblo region of northern Arizona (Hopi); *Athabaskan,* divided into three geographically distinct groups of languages—Northern (the valleys of the Mackenzie and Yukon, from just short of Hudson's Bay west to Cook Inlet, Alaska, and from Great Bear Lake and the Mackenzie delta south to the headwaters of the Saskatchewan), Pacific (two disconnected areas, one in southwestern Oregon and northwestern California, the other a little south of this in California), and Southern (large parts of Arizona and New Mexico, with adjoining regions of Utah, Texas and Mexico)—besides isolated enclaves in southern British Columbia, Washington and northern Oregon; and *Salishan,* in southern British Columbia, most of Washington, and northern Idaho and Montana, with two isolated offshoots, one (Bella Coola) to the north on the British Columbia coast, the other (Tillamook) to the south in northwestern Oregon.

The remaining 46 stocks, according to Powell's classification, in alphabetical order, are: *Atakapa* (Gulf coast of Louisiana and Texas); *Beothuk* (Newfoundland; extinct); *Chimakuan* (northwestern Washington); *Chimariko* (northwestern California);

Chinook (lower Columbia river, in Washington and Oregon); ***Chitimacha*** (southern Louisiana); ***Chumash*** (southwestern California); ***Coahuiltecan*** (lower Rio Grande, in Texas and Mexico); *Coos* (Oregon coast); ***Costanoan*** (western California south of San Francisco Bay); ***Esselen*** (southwestern California; extinct); *Haida* (Queen Charlotte Islands and part of southern Alaska); ***Kalapuya*** (northwestern Oregon); ***Karankawa*** (Texas coast); ***Karok*** (northwestern California); ***Keres*** (certain Rio Grande pueblos, New Mexico); ***Kiowa*** (southern Plains, in Kansas, Colorado, Oklahoma, and Texas); ***Kootenay*** (upper Columbia river, in British Columbia and adjoining parts of Idaho and Montana); ***Lutuami***, consisting of Klamath and Modoc (southern Oregon and northeastern California); ***Maidu*** (eastern part of Sacramento valley, California); ***Miwok*** (central California); ***Piman*** or Sonoran (southern Arizona and south into Mexico as far as the state of Jalisco); ***Pomo*** (western California north of San Francisco Bay); ***Sahaptin*** (middle Columbia River valley, in Washington, Oregon and Idaho); ***Salinan*** (southwestern California); ***Shastan*** or Shasta-Achomawi (northern California and southern Oregon); ***Takelma*** (southwestern Oregon); ***Tanoan*** (certain pueblos in New Mexico, Arizona, and originally also in Chihuahua, Mexico); ***Timuqua*** (Florida; extinct); ***Tlingit*** (southern Alaska); ***Tonkawa*** (Texas); ***Tsimshian*** (western British Columbia); ***Tunica*** (Mississippi River, in Louisiana and Mississippi); ***Waiilatpuan***, consisting of Molala and Cayuse (northern Oregon); ***Wakashan***, consisting of Kwakiutl and Nootka (coast of British Columbia); ***Washo*** (western Nevada and eastern California); ***Wintun*** (north central California); ***Wiyot*** (northwestern California); ***Yakonan*** (Oregon coast); ***Yana*** (northern California); ***Yokuts*** (south-central California); ***Yuchi*** (Savannah river, in Georgia and South Carolina); ***Yuki*** (western California); ***Yuman*** (lower Colorado River valley, in Arizona, southern California and south into all or most of lower California); ***Yurok*** (northwestern California); ***Zuñi*** (pueblo of New Mexico). To these was later added, as distinct from Yakonan, ***Siuslaw*** (Oregon Coast).

This complex classification of native languages in North America is very probably only a first approximation to the historic truth. There are clearly far-reaching resemblances in both structure and vocabulary among linguistic stocks classified by Powell as genetically distinct. Certain resemblances in vocabulary and phonetics are undoubtedly due to borrowing of one language from another, but the more deep-lying resemblances, such as can be demonstrated, for instance, for Shoshonean, Piman, and Nahuatl (Mexico) or for Athabaskan and Tlingit, must be due to a common origin now greatly obscured by the operation of phonetic laws, grammatical developments and losses, analogical disturbances, and borrowing of elements from alien sources.

It is impossible to say at present what is the irreducible number of linguistic stocks that should be recognized for America north of Mexico, as scientific comparative work on these difficult languages is still in its infancy. The following reductions of linguistic stocks which have been proposed may be looked upon as either probable or very possible: 1, ***Wiyot*** and ***Yurok***, to which may have to be added Algonkian (of which Beothuk may be a very divergent member); 2, ***Iroquoian*** and ***Caddoan***; 3, ***Uto-Aztekan***, consisting of Shoshonean, Piman and Nahuatl; 4, ***Athabaskan*** and ***Tlingit***, with ***Haida*** as a more distant relative; 5, ***Mosan***, consisting of Salish, Chimakuan and Wakashan; 6, ***Atakapa***, ***Tunica*** and ***Chitimacha***; 7, ***Coahuiltecan***, ***Tonkawa*** and ***Karankawa***; 8, ***Kiowa*** and ***Tanoan***; 9, ***Takelma***, ***Kalapuya*** and ***Coos-Siuslaw-Yakonan***; 10, ***Sahaptin***, ***Waiilatpuan*** and ***Lutuami***; 11, a large group known as ***Hokan***, consisting of Karok, Chimariko, Shastan, Yana, Pomo, Washo, Esselen, Yuman, Salinan, Chumash, and in Mexico, Seri and Chontal; 12, ***Penutian***, consisting of Miwok-Costanoan, Yokuts, Maidu and Wintun.

A more far-reaching scheme than Powell's, suggestive but not demonstrable in all its features at the present time, is Sapir's.

These linguistic classifications, shown in the next column, do not correspond at all closely to the racial or sub-racial lines that have been drawn for North America, nor to the culture areas into which the tribes have been grouped by ethnographers. Thus, the Athabaskan stock counts among its tribes repres-

Proposed Classification of American Indian Languages North of Mexico (and Certain Languages of Mexico and Central America)

I. *Eskimo-Aleut*

II. *Algonkin-Wakashan*

1. Algonkin-Ritwan
   - (1) Algonkin
   - (2) Beothuk (?)
   - (3) Ritwan
     - (a) Wiyot
     - (b) Yurok
2. Kootenay
3. Mosan (Wakashan-Salish)
   - (1) Wakashan (Kwakiutl-Nootka)
   - (2) Chimakuan
   - (3) Salish

III. *Nadene*

1. Haida
2. Continental Nadene
   - (1) Tlingit
   - (2) Athabaskan

IV. *Penutian*

1. Californian Penutian
   - (1) Miwok-Costanoan
   - (2) Yokuts
   - (3) Maidu
   - (4) Wintun
2. Oregon Penutian
   - (1) Takelma
   - (2) Coast Oregon Penutian
     - (a) Coos
     - (b) Siuslaw
     - (c) Yakonan
   - (3) Kalapuya
3. Chinook
4. Tsimshian
5. Plateau Penutian
   - (1) Sahaptin
   - (2) Waiilatpuan (Molala-Cayuse)
   - (3) Lutuami (Klamath-Modoc)
6. Mexican Penutian
   - (1) Mixe-Zoque
   - (2) Huave

V. *Hokan-Siouan*

1. Hokan-Coahuiltecan
   - A. Hokan
     - (1) Northern Hokan
       - (a) Karok, Chimariko, Shasta-Achomawi
       - (b) Yana
       - (c) Pomo
     - (2) Washo
     - (3) Esselen-Yuman
       - (a) Esselen
       - (b) Yuman
     - (4) Salinan-Seri
       - (a) Salinan
       - (b) Chumash
       - (c) Seri
     - (5) Tequistlatecan (Chontal)
   - B. Subtiaba-Tlappanec
   - C. Coahuiltecan
     - (1) Tonkawa
     - (2) Coahuilteco
       - (a) Coahuilteco proper
       - (b) Cotoname
       - (c) Comecrudo
     - (3) Karankawa
2. Yuki
3. Keres
4. Tunican
   - (1) Tunica-Atakapa
   - (2) Chitimacha
5. Iroquois-Caddoan
   - (1) Iroquoian
   - (2) Caddoan
6. Eastern group
   - (1) Siouan-Yuchi
     - (a) Siouan
     - (b) Yuchi
   - (2) Natchez-Muskogian
     - (a) Natchez
     - (b) Muskogian
     - (c) Timucua (?)

VI. *Aztec-Tanoan*

1. Uto-Aztekan
   - (1) Nahuatl
   - (2) Piman
   - (3) Shoshonean
2. Tanoan-Kiowa
   - (1) Tanoan
   - (2) Kiowa
3. Zuñi (?)

entatives of four of the major culture areas of the continent: Plateau-Mackenzie area, southern outlier of West Coast area, Plains area and Southwestern area.

The aboriginal languages of North America differ from each other in both phonetic and morphological respects. Some are polysynthetic (or "holophrastic") in structure, such as Algonkian, Yana, Kwakiutl-Nootka, or Eskimo. Others, like Takelma and Yokuts, are of an inflective cast and may be compared, for structural outlines, to Latin or Greek; still others, like Coos, while inflective, have been reduced to the relatively analytic status of such a language as English; agglutinative languages of moderate complexity, comparable to Turkish, are common, say Shoshonean or Sahaptin.

The term "polysynthetic" indicates that the language is far more than ordinarily synthetic in form, that the word embodies many more or less concrete notions that would in most languages be indicated by the grouping of independent words in the sentence. The Yana word *yābanaumawildjigummaha'nigi* "let us, each one (of us), move indeed to the west across (the creek)!" is "polysynthetic" in structure. It consists of elements of three types—a nuclear element or "stem," *yā-* "several people move"; formal

elements of mode (*-ha-*, hortatory) and person (*-nigi* "we"); and elements of a modifying sort which cannot occur independently but which nevertheless express ideas that would ordinarily be rendered by independent words (*-banauma-* "everybody," *-wil-* "across," *-dji-* "to the west," *-gumma-* "indeed"). Such constructions are not uncommon in native America but are by no means universal

Phonetically these languages differ enormously. Some, like Pawnee (Caddoan stock), have a simple consonantal structure, others make all manner of fine consonantal discriminations and possess many strange types of consonants, such as voiceless *l*-sounds, "glottalized" consonants, and velar *k*-sounds, that are infrequent elsewhere. Kutchin, an Athabaskan language of Alaska, possesses no less than 55 consonantal "phonemes," distinct consonantal elements of the total phonetic pattern. A considerable number of the native languages of North America are pitch languages, *i.e.*, they use pitch differences in otherwise similar syllables to make lexical or grammatical distinctions. Such languages are Tlingit, Athabaskan (certain dialects of this group have lost pitch as an inherently necessary element of language), Takelma, Shasta-Achomawi, Yuman, Tanoan. Navaho may serve as an example of such a pitch language. Every syllable in its words is definitely high or low in pitch, or, less frequently, has a falling or rising tone. Thus, *bini'* means "his nostril" if the two syllables have a high tone, "his face" if they have a low tone, and "at his waist, centre" if the first syllable is low and the second high; *yāzid* means "you pour it (sandy mass) down" if the first syllable is low and the second high, but "I have poured it down" if both are low.

The six major linguistic groups of Sapir's scheme may be characterized as follows:

I. The *Eskimo-Aleut* languages are "polysynthetic" and inflective; use suffixes only, never prefixes, reduplication, inner stem modification, or compounding of independent stems; have a great elaboration of the formal aspect of verb structure, particularly as regards mode and person; and make a fundamental distinction between the transitive and intransitive verb, to which corresponds the nominal case distinction of agentive-genitive and absolutive (or objective).

II. The *Algonkin-Wakashan* languages, too, are "polysynthetic" and, especially as regards Algonkian, inflective; make use of suffixes, to a much less extent, particularly in Algonkian and Ritwan, of prefixes; have important inner stem modifications, including reduplication; have a weak development of case; and illustrate to a marked degree the process of building up noun and verb themes by suffixing to stems local, instrumental, adverbial, and concretely verbalizing elements.

III. The *Nadene* languages, probably the most specialized of all, are tone languages and, while presenting a superficially "polysynthetic" aspect, are built up, fundamentally, of monosyllabic elements of prevailingly nominal significance which have fixed order with reference to each other and combine into morphologically loose "words"; emphasize voice and "aspect" rather than tense; make a fundamental distinction between active and static verb forms; make abundant use of postpositions after both nouns and verb forms; and compound nominal stems freely. The radical element of these languages is probably always nominal in force and the verb is typically a derivative of a nominal base, which need not be found as such.

IV. The *Penutian* languages are far less cumbersome in structure than the preceding three but are more tightly knit, presenting many analogies to the Indo-European languages; make use of suffixes of formal, rather than concrete, significance; show many types of inner stem change; and possess true nominal cases, for the most part. Chinook seems to have developed a secondary "polysynthetic" form on the basis of a broken down form of Penutian; while Tsimshian and Maidu have probably been considerably influenced by contact with Mosan and with Shoshonean and Hokan respectively.

V. The *Hokan-Siouan* languages are prevailingly agglutinative; tend to use prefixes rather than suffixes for the more formal elements, particularly the pronominal elements of the verb; distinguish active and static verbs; and make free use of compounding of stems and of nominal incorporation.

VI. The *Aztec-Tanoan* languages are moderately "polysynthetic"; suffix many elements of formal significance; make a sharp formal distinction between noun and verb; make free use of reduplication, compounding of stems and nominal incorporation; and possess many postpositions. Pronominal elements, in some cases nouns, have different forms for subject and object but the subject is not differentiated, as in types I. and IV., for intransitive and transitive constructions. (E. Sa.)

Powell, "Indian Linguistic Families of America north of Mexico," Bureau of Ethnology, 7th *Annual Report*, pp. 1–142 (Washington, 1891); Franz Boas, "Handbook of American Indian Languages," Bureau of American Ethnology, *Bull. 40* (pt. 1, 1911; pt. 2, 1922); P. Rivet, "Langues de l'Amérique du Nord," pp. 607–628 of A. Meillet et M. Cohen, *"Les Langues du Monde* (Paris, 1924).

Mexican and Central American Languages.—The classification of the native languages of Middle America is not in quite so advanced a stage as is that of the many languages spoken north of Mexico. The languages are, some of them, spoken by large populations, numbering millions, as in the case of Nahuatl (or Mexican) and the Maya of Yucatan; others are confined to very small groups, like the Subtiaba-Tlappanec of Nicaragua and Guerrero, or are extinct, as is Waïcuri in Lower California. Nahuatl, Maya (with Quiche, Kekchi, and Cakchiquel, which belong to the Mayan stock), and Zapotec were great culture languages which had developed ideographic methods of writing.

The languages of Middle America may be conveniently grouped into three main sets: A., southern outliers of stocks located chiefly north of Mexico; B., stocks spoken only in Mexico and Central America, so far as is known at present; C., northern outliers of South American stocks. It is quite probable that relationships will eventually be discovered between some of the languages of group B and languages lying further north.

To group A belong three distinct stocks: *Uto-Aztekan*, with two subdivisions, *Sonoran* (or *Piman*), spoken in a large number of dialects in northern Mexico, and *Nahuatl* (or *Aztek*), spoken in central Mexico and in a number of isolated southern enclaves —the Pacific coast of Oaxaca (Pochutla), three disconnected areas in Salvador and Guatemala (Pipil), two areas in Nicaragua and one in Costa Rica (Nicarao), and the Chiriqui region of Costa Rica (Sigua), of which dialects Nicarao and Sigua are now extinct—with *Cuitlateco* of Michoacan as a doubtful member of the stock; *Hokan-Coahuiltecan*, represented by *Hokan* proper, which includes Seri (coast of Sonora), Yuman (in Lower California), and Tequistlateco or Chontal (coast of Oaxaca), by *Coahuiltecan* (Pakawan), of the lower Rio Grande, and by *Subtiaba-Tlappanec*, which is spoken in two small areas in Guerrero, one in Salvador, and one in Nicaragua; and *Athabaskan* (Apache tribes of Chihuahua and Coahuila).

The Middle American languages proper (group B) may, with reservations, be classified into 15 linguistic stocks, which in alphabetic order, are: *Chinantec* (Oaxaca and western Vera Cruz); *Janambre* (Tamaulipas; extinct); *Jicaque* (northern Honduras); *Lenca* (Honduras and Salvador); *Mayan* (Yucatan and neighboring states of southern Mexico, British Honduras, western Honduras, and Guatemala), with an aberrant dialect group, *Huastec*, in the northeastern coast region of Mexico (Vera Cruz, San Luis Potosi, Tamaulipas); *Miskito-Sumo-Matagalpa*, consisting of three distinct language groups: *Miskito* (coast of Nicaragua and Honduras), *Sumo-Ulua* (eastern Nicaragua and southern Honduras), and *Matagalpa* (Nicaragua; a small enclave, Cacaopera, in Salvador); *Mixe-Zoque-Huave*, spoken in four disconnected groups, *Mixe-Zoque* (Oaxaca, Vera Cruz, Chiapas, and Tabasco), *Tapachultec* (southeastern Chiapas; extinct), *Aguacatec* (Guatemala, extinct), and *Huave* (coast of Oaxaca); *Mixtec-Zapotec*, a group of languages that some consider as composed of four independent stocks: *Mixtec* (Guerrero, Puebla, and western Oaxaca), *Amusgo* (Guerrero and Oaxaca), *Zapotec* (Oaxaca), and *Cuicatec* (northern Oaxaca); *Olive* (Tamaulipas; extinct); *Otomian*, consisting of three distinct groups: *Otomi* (large part of central Mexico), *Mazatec* (Guerrero,

Puebla, Oaxaca; includes *Trique* and *Chocho*), and the geographically distant *Chiapanec-Mangue* (*Chiapanec* in Chiapas; *Mangue* and related languages in three disconnected areas in Nicaragua and Costa Rica); *Paya* (Honduras); *Tarascan* (Michoacan); *Totonac* (Hidalgo, Puebla, and coast of Vera Cruz); *Waïcuri* (southern part of Lower California; extinct); *Xinca* (southeastern Guatemala).

The outliers from South America are two: *Carib* (coast of Honduras and British Honduras; transferred in post-Columbian times from the Antilles); *Chibchan* (Costa Rica and Panama). In the West Indies two South American stocks were represented, *Carib* and *Arawak*, the latter constituting an older stream which had overrun the Greater Antilles and penetrated into Florida.

As to the languages of group B, some connect Chinantec, Mixtec-Zapotec, and Otomian in one great linguistic stock, *Mixtec-Zapotec-Otomi*. Both Xinca and Lenca (also Paya and Jicaque?) may be remote southern outliers of the Penutian languages of North America. Waïcuri may have been related to Yuman. It is by no means unlikely that such important Middle American stocks as Mayan, Totonac, and Tarascan may also belong to certain of the larger stock groupings that have been suggested for North America; *e.g.*, Maya may fit into the Hokan-Siouan framework, Tarascan into Aztek-Tanoan.

Middle America, in spite of its special cultural position, is distinctly a part of the whole North American linguistic complex and is connected with North America by innumerable threads. On the other hand, there seems to be a much sharper line of linguistic division, distributionally speaking, between Middle and South America. This line is approximately at the boundary between Nicaragua and Costa Rica; allowances being made for Nahuatl and Otomian enclaves in Costa Rica and for an Arawak colony in Florida, we may say that Costa Rica, Panama, and the West Indies belong linguistically to South America. The Chibchan, Arawak, and Carib stocks of the southern continent were obviously diffusing northward at the time of the Conquest, but evidence seems to indicate that for Mexico and Central America as a whole the ethnic and linguistic movement was from north to south. Middle America may be looked upon as a great pocket for the reception of a number of distinct southward-moving peoples and the linguistic evidence is sure to throw much light in the future on the ethnic and culture streams which traversed these regions.

Two linguistic groups seem to stand out as archaically Middle American: Miskito-Sumo-Matagalpa, in Central America, and Mixtec-Zapotec-Otomi, with its center of gravity in southern Mexico. The latter of these sent offshoots that reached as far south as Costa Rica. The Penutian languages, centered in Oregon and California, must early have extended far to the south, as they seem to be represented in Mexico and Central America by Mixe-Zoque, Huave, Xinca, and Lenca. These southern offshoots are now cut from their northern cognate languages by a vast number of intrusive languages, *e.g.*, Hokan and Aztek-Tanoan. The Mayan languages, apparently of Hokan-Siouan type, may have drifted south at about an equally early date. Presumably later than the Penutian and Mayan movements into Middle America is the Hokan-Coahuiltecan stream, represented by at least three distinct groups—Coahuiltecan (N.E. Mexico), Subtiaba-Tlappanec (Guerrero, Nicaragua), and a relatively late stream of Hokan languages proper (Yuman; Seri; and Chontal in Oaxaca). Not too early must have been the Uto-Aztekan movement to the south, consisting of an advance guard of Nahuatl-speaking tribes, a rear guard of Sonoran-speaking tribes (Cora, Huichol, Tarahumare, Tepehuane). The Nahuatl language eventually pushed south as far as Costa Rica. Last of all, the Apache dialects of Chihuahua brought into Mexico the southernmost outpost of the Nadene group of languages, which extend north nearly to the Arctic. (E. SA.)

CENTRAL BANK. Central banks are institutions charged with the function of regulating the supply, cost and use of money with a view to promoting national and international economic stability and welfare. They differ from other banking institutions in that they are vested with the public interest and are not operated primarily as profit-making business enterprises.

Evolution.—Modern central banks are the outcome of a long evolution. Originally many of them were established for the purpose of serving the state by extending loans and of providing currency of uniform value in adequate amount for the needs of the country. They became the principal, in many countries the only, issuers of paper money. In modern times the principal function of central banks is regulation of the supply and use of money in the service of commerce and industry, but in times of emergency, such as war, they become in the main instruments for facilitating government finance.

Heavy reliance on central banks for government financing during World War I and the inflationary excesses which subsequently developed led to a movement for strict limitation of government borrowing from central banks, but the necessities of World War II largely subordinated such limitations. In wartime the central bank, as all other institutions, must support the government's war needs and its stabilizing function becomes secondary to this purpose.

During the 1920s and 1930s most countries went through booms and depressions caused largely by nonmonetary factors and not traceable to variations in the supply or cost of money. The viewpoint gradually developed that a central bank is but one of many public agencies which must act in concert if the purpose of establishing and maintaining a stable and expanding volume of national income and a rising level of economic wellbeing is to be achieved.

Older institutions have nothing in their charters indicative of the broad modern concept of central bank functions, but in practice it has been widely recognized. In charters of more recently established central banks, such as the Bank of Canada, it is explicitly stated.

Functions.—With these broad objectives as their goal, central banks have the following principal functions and authorities: (1) creation of money by issuing notes and by creating bankers' balances which through custom or law must be held by commercial banks as reserves in an amount proportionate to their liabilities; (2) influencing the volume, cost and use of money by expanding and contracting bankers' cash, or reserves. This the central bank accomplishes by establishing and varying the rate at which it will make advances or discounts on the initiative of commercial banks or the market; by purchasing or selling on its own initiative such securities as government obligations and acceptances (or bills), and, in some countries, principally the United States, by increasing or decreasing the ratio of reserves to deposits that commercial banks are required to hold. (3) In addition to these general influences on the use of money, some central banks have the power to influence specific uses of money. For example, in the United States the Federal Reserve board of governors has authority to prescribe margins for stock market loans, and also (on an emergency war basis) to regulate certain types of consumer credit. In some countries limited selective regulation of the use of money is undertaken by varying the rate at which paper originating from different types of transactions will be discounted by the central bank. Central banks (4) serve as fiscal agents of the government; (5) perform numerous services for the banking system, among which the most important is check clearance; (6) serve as correspondents of central banks of other countries; and (7) supervise banks with a view to enforcing compliance with banking laws and maintenance of sound banking conditions. This function is performed by central banks of different countries in different ways. In England, for example, which has a highly centralized branch banking system, the central bank performs this function largely through its informal but potent influence on the management of the joint-stock banks. In the United States, where the vast majority of more than 14,000 banks are independent, responsibility for bank supervision is vested in the central bank by law; it is, however, shared with certain

other government agencies.

Banks of Issue.—Most central banks hold a monopoly of note issue, which in the case of some older institutions was acquired by gradual absorption or extinction of rival issues. In modern times the notes of new central banks may be launched while the circulation of older currency, issued by banks or government treasuries, continues temporarily or permanently.

Up to the end of 1944, national governments of the following countries had granted a monopoly of issue to their central banks: *Europe:* France, Belgium, the Netherlands, Switzerland, Norway, Sweden, Denmark, Finland, Estonia, Latvia, Lithuania, Spain, Portugal, Italy, Hungary, Poland, Czechoslovakia, Bulgaria, Rumania, Yugoslavia, Greece, Albania; *Middle East:* Turkey, Egypt, Iran; *Far East and Oceania:* China (monopoly to Central Bank of China, 1942), Japan, Australia, New Zealand; *Africa:* Union of South Africa; *North and Central America:* Mexico, Costa Rica, Nicaragua, Guatemala, El Salvador; *South America:* Argentina, Bolivia, Chile, Colombia, Ecuador, Peru, Paraguay (1943), Venezuela (1939).

Colonial central banks or banks of issue exist in some French, Belgian, Dutch, Portuguese and Japanese colonies. In 1944 the Caisse Centrale de la France d'Outre-Mer (formerly "Caisse Centrale de la France Libre") was authorized to function as a central bank of a unique type, directing the credit policy of colonial banks of issue in Free French territory.

Some leading central banks do not (1945) have a monopoly of note issue. Note circulation of the 12 Federal Reserve banks of the United States, Dec. 31, 1944, amounted to $21,482,000,000 while other paper currency (silver certificates of the U.S. treasury and other note issues of the government) amounted to $2,615,000,000, only part of which was to be retired.

The Bank of England has a monopoly of note issue for England and Wales but eight Scottish banks have fixed quotas totalling £2,676,350 and quotas of six banks in Northern Ireland totalled £2,197,792 (approved by treasury up to Dec. 23, 1944). Issues exceeding these quotas must be covered by gold or other legal tender. After the opening of the Bank of Canada in 1935, chartered bank notes were being reduced by schedule and were eventually to be taken over by the central bank. A similar situation existed in Eire after the Central Bank of Ireland was established in 1942. In British India, government notes circulate with those of the reserve bank. Currency of the State Bank of the U.S.S.R. serves only as bank or deposit currency. The circulating medium, besides coin, is rouble notes of the state treasury. Germany's note circulation (1944) included, besides Reichsbank notes, the notes of the Deutsche Rentenbank, the issue of which was extended by decrees of 1930 and 1939.

During World War II the axis powers set up in several occupied countries new banks of issue or central banks whose notes were designed to supersede the national currency. Disposal of these superimposed currencies, as well as of the military currency circulated by Germany and Japan in occupied countries and by the allies in liberated countries, presented a complicated postwar problem.

Relation to the State.—Relation of the central bank to the state, more particularly to the fiscal authority, varies from country to country, but in general the central bank has responsibility for the volume and cost of money, while the fiscal authority has responsibility for meeting government expenses through taxation and borrowing. It is generally believed that, since the two functions and responsibilities are distinct and may at times indicate different courses of action, the public good is served best by keeping them in separate institutions. It is increasingly recognized, however, that while the central bank has the obligation to formulate its policies in accordance with its own judgment and in ordinary times should have a large measure of autonomy, in times of national emergency the will of the fiscal authority must prevail. At such times the central bank must function chiefly as an adviser, the degree of its influence depending on the confidence which it commands with other branches of the government and the general public.

In some countries the central bank is owned in whole or in part by the state, in others it is privately owned. Private ownership of central banks, however, is in effect merely a contribution of private capital to a public institution operated for a public purpose.

Economic Intelligence.—Enlargement of the objectives which the central bank must aim to achieve has resulted in increasing emphasis on the maintenance of effective economic intelligence services at central banks. The interrelationships of economic forces make it necessary for the policy-making authorities of central banks to keep abreast of all important economic developments, domestic and foreign, with a view to enabling them not only to determine their own policies in the light of all available facts and analyses, but also to be in a position to give sound counsel to other public bodies that formulate other phases of the nation's interrelated economic policies.

CENTRAL ELECTRICITY BOARD. A British body corporate appointed by the minister of transport under the terms of the Electricity (Supply) Acts, 1926 and 1935, to organize and control the generation of electricity throughout Great Britain. This it has effected by means of the "grid" system (*see* ELECTRICITY SUPPLY: COMMERCIAL ASPECTS) which, constructed at a cost of some £30,000,000, at the end of 1938 comprised 4,378 mi. of transmission lines and 304 switching and transforming stations with an aggregate transforming capacity of 10,422,000 kva., and during the year had an output of 24,376,000,000 units compared with the 4,016 units sold in the same area in 1925. The board consists of a chairman and seven members; the first chairman, Sir Andrew Duncan, was succeeded in 1935 by Sir Archibald Page, the former chief engineer and manager. The board has borrowing powers up to £60,000,000. Annual reports and statements of accounts are published.

Before the passing of the 1926 act there were over 500 unconnected generating stations in Great Britain, 32 of which supplied half the power; by means of the act much of the capital extravagance entailed by this lack of co-ordination was eliminated, the general level of the cost of production was lowered, and the availability of electricity throughout the country increased; the larger and more efficient generating stations became "selected stations" and were interconnected by the grid with each other and with the systems of authorized undertakers not owning selected stations, and great economies were effected by the use of the more efficient stations for the long-hour or base load and the restriction of the use of the less efficient stations to the short-hour or peak load, many of these latter being completely closed during the summer months. The output of all selected stations is purchased by the board and is sold by them to the distributing authorities, including the owners of the stations themselves, at a tariff fixed by the board and approved by the Electricity Commissioners; authorized undertakers have the right to demand supplies from the board, and under the 1935 act the board is empowered to supply electricity to railway companies for traction purposes, which it now does in the case of the Southern railway.

At the end of 1938 the selected stations numbered 137 with a total installed capacity of 8,264,160 kw. (as against 3,096,000 kw. in 1925), and the board controlled in addition 35 nonselected stations, the operation of the whole 171 being so controlled that only 30 ran for the full year. Of the 560 distributing undertakings 217 were supplied directly and a further 300 indirectly by the board, which in 1938 produced 97.2% of the electricity consumption of the country.

The offices of the board are in Trafalgar Buildings, Charing Cross, London.

CENTRAL FALLS, a city of Providence county, Rhode Island, U.S.A., on the Blackstone river, 5 mi. N. of Providence; served by the New York, New Haven and Hartford railroad. The

population in 1950 was 23,550; in 1940 it was 25,248 by federal census. The river furnishes water power for large manufacturing industries (chiefly cotton mills). A settlement was made there about 1763.

About 1780 a chocolate mill was erected, and until 1827 the town was called Chocolateville. It was incorporated as the Central Falls Fire District of Smithfield in 1847, and in 1896 was chartered as a city.

CENTRALIA, a city of southern Illinois, U.S., about 60 mi. E. of Saint Louis, in Marion and Clinton counties. It is on federal highway 51 and state highway 161, and is served by the Illinois Central, Burlington, Southern and the Missouri-Illinois railways. The population in 1950 was 13,863.

Centralia is in a fertile fruit-growing and dairying region, and there are coal mines and oil wells in the vicinity. The city has a large wholesale trade. Two of the railroads have division repair shops there, and there are several other manufacturing industries.

Centralia was founded in 1853 by the Illinois Central Railroad company, and was chartered as a city in 1859.

CENTRALIA, a city of Lewis county, Washington, U.S., on the Pacific highway, about halfway between Seattle and Portland. It is served by four transcontinental railways: the Chicago, Milwaukee, St. Paul and Pacific; the Great Northern; the Northern Pacific and the Union Pacific. The population was 8,657 in 1950, and was 7,414 in 1940 by the federal census. Chehalis, the county seat, lies 4 mi. S., and between the two cities are the southwestern Washington fairgrounds. Centralia has saw and shingle mills, furniture and concrete culvert factories and railroad shops, and gloves, shoes, knit goods and bakery supplies are produced. In Borst park, 1½ mi W. of the city, is a blockhouse built by the early settlers as a stronghold against the Indians. Centralia is situated on the Cochrain Donation claim. It was laid out by George Washington, a former Negro of Cochrain, who became the owner of the land on the death of his master in 1852, and at first it was called Washington's Addition. Later it was known for a few years as Skookumchuck Station, and then as Centerville, until the present name was adopted in 1887. In 1914 a commission form of government was adopted. The municipal water and power system is operated by the city. Once dependent upon lumber industry, the main industries are now railroading and retail trade.

CENTRAL INDIA, the name given by the British to a collection of Indian states which formed a separate agency until India's independence. Central India must not be confused with the Central Provinces. It consisted of two large detached tracts of country which, with Jhansi as a pivot, spread outward east and west into the peninsula, reaching northward to within about 50 mi. of Agra and southward to the valley of the Nerbudda and the Vindhya and Satpura ranges. On the north and northeast it was bounded by the United Provinces; on the west and southwest by Rajputana and part of the Bombay Presidency; on the south and east by the Central Provinces and Chota Nagpur; the Jhansi district of the United Provinces and the Saugor district of the Central Provinces separated the two tracts.

Before the removal of Gwalior from the agency in 1921 Central India could be roughly described as an enormous triangle with the Nerbudda and Son rivers forming its hypotenuse, and having for one side the valley of the Ganges and for the other the Chambal river and the Chittor hills. The Central India agency, therefore, was not a compact administration but a collection of states varying in area, revenue and population, and in their relationship to the paramount power. All, however, were subject to the political control of the resident, or agent to the governor general, who had his headquarters at Indore. According to the 1941 census the total area of the agency was 52,047 sq.mi. and the total population 7,506,427.

History.—In the 7th century B.C. northern India and part of the Deccan were divided into 16 principalities, the 16 *Mahājanapadas* of the Buddhist *Anguttara Nikāya*. Two of the more important of these kingdoms, Avanti with its capital at Ujjain and Vatsa, of which the chief town was Kausambhi, roughly corresponded to the territories included in the Central India agency. These two kingdoms were later incorporated into the vast Maurya empire of Chandragupta and Asoka.

From the Junagadh rock inscription it may be inferred that in the 2nd century A.D. Rudradaman, the greatest of the western satraps, ruled over Avanti, that is, eastern and western Malwa. Both Avanti and Vatsa were included in the Gupta empire under Chandragupta II (*c.* 385–*c.* 413). Although the extent of Harsha's dominions in the first half of the 7th century is a matter of controversy, modern opinion inclines to the view that they embraced these two areas. In the 9th century Central India formed a bone of contention between the Gurjara-Pratiharas of Kanauj and the Rashtrakutas of the Deccan. The evidence is conflicting as both sides boast of their victories, but it appears to have been an indecisive conflict with the Nerbudda as a fluctuating frontier. It was not until the early 13th century that the Moslem invaders began to penetrate into Central India.

In 1234, Iltutmish, the sultan of Delhi, entered Malwa and captured Bhilsa and Ujjain. With the decline of Tughlak power toward the end of the next century, Central India no longer acknowledged the suzerainty of Delhi and was divided into independent kingdoms, the most important of which was the Moslem kingdom of Malwa. Malwa's independence came to an end in 1562 when it was conquered by Akbar. It remained a province of the Mogul empire until the decline of Mogul power in the first half of the 18th century, when Central India was overrun by the Marathas who had rebelled against the central government of Delhi. Central India was dominated by the Maratha *peshwas* until the third battle of Panipat (1761), after which it was split up among the Maratha generals, the most important of whom were Sindhia of Gwalior and Holkar of Indore.

The marquess Wellesley was the first governor general to feel that it was impossible to live in amity with the Marathas and that the time had come for the British to stand forth as the paramount power. He therefore declared war on their chiefs but was recalled before he was able completely to crush their power. His immediate successors adopted a policy of nonintervention with the result that Central India became a prey to anarchy and was continually ravaged by plundering bands of Pindaris and Pathans whom the Marathas were powerless to control. It was left for the marquess of Hastings to complete the work of Wellesley; and, by 1818, these robber bands and their protectors, the Marathas, had been crushed. As a result of this campaign the British became the paramount power in India south of Sind and the Punjab. The settlement and pacification of Central India after this campaign was the work of Sir John Malcolm. Between 1830 and 1835 the Thugs who infested this area were suppressed by Capt. (afterward Sir) William Sleeman. Apart from disturbances during the Mutiny of 1857 Central India under British rule enjoyed unbroken peace.

The term Central India was officially applied at first to Malwa alone; but in 1854 Bundelkhand and Baghelkhand were added to Malwa to form the Central India agency, and Sir Robert Hamilton was appointed agent to the governor general. In 1901, for administrative purposes, it was divided into the following eight units, two of which were classed as residencies and six as agencies: (1) Gwalior residency (Gwalior state and 11 small states and estates); (2) Indore residency (Indore state and 2 estates); (3) Baghelkhand agency (Rewa state and 11 minor states and estates); (4) Bhopal agency (Bhopal state and 21 minor states and estates); (5) Bhopawar agency (Dhar and Barwani states and 20 minor states and estates); (6) Bundelkhand agency (Datia, Orchha, Samthar, Charkhari, Chhattarpur and Panna states and 17 minor states and estates); (7) Indore agency (Dewas Senior and Dewas Junior and 4 estates); (8) Malwa agency (Jaora and Ratlam states and 12 estates).

The chief administrative changes after 1901 were: (1) the abolition of the Indore agency in 1907 and its amalgamation with the Malwa agency; (2) the removal of Gwalior from the agency in 1921; (3) the amalgamation in 1931 of the Baghelkhand and Bundelkhand agencies.

After the achievement of Indian independence the Central India agency was divided into two separate administrations: Madhya Bharat (*q.v.*; the united state of Gwalior, Indore and Malwa);

and Vindhya Pradesh (which includes the 25 states of Baghelkhand, and Bundelkhand, of which Rewa is the largest). Bhopal (*q.v.*) was detached to form a separate entity.

CENTRAL PROVINCES AND BERAR, a former province of British India and (from 1947 to 1950) of the dominion of India; from Jan. 26, 1950, a "part A" (governor's) state of the republic of India under the name of MADHYA PRADESH. The Central Provinces of India were formed in 1862, and were augmented in 1903 by the Hyderabad assigned districts of Berar, which in 1902 had been leased in perpetuity to the British government by the nizam, at an annual rent of 25 lakhs of rupees. In 1905 most of the Sambalpur district and five Oriya-speaking states were transferred to Bengal, and five Hindi-speaking states from Chota Nagpur received in exchange. The province, therefore, now consisted of the four divisions of Jubbulpore, Nagpur, Chhattisgarh and Berar, which were divided into the 19 districts of Saugor, Jubbulpore, Mandla, Hoshangabad, Nimar, Betul, Chhindwara, Wardha, Nagpur, Chanda, Bhandara, Balaghat, Raipur, Bilaspur, Drug, Amraoti, Akola, Buldana and Yeotmal. The state capital is Nagpur, but from April to July the seat of government is at Pachmarhi. The province was enlarged in 1948 by the incorporation of the feudatory princely states of Bastar, Changbhakar, Chhuikhadan, Jashpur, Kanker, Kawardha, Khairagarh, Korea, Makrai, Nandgaon, Raigarh, Sakti, Sarangarh, Surguja and Udaipur, so increasing the area by more than 38,000 sq.mi. and the population by more than 4,000,000. Total area of Madhya Pradesh (1951) 130,272 sq.mi.; total population (1951 census) 21,247,533.

South of the Vindhyan plateau are the Nerbudda valley districts extending from Jubbulpore on the east to north Nimar on the west. South of these again is the great Satpura range of hills and plateaus upon which are situated the four plateau districts of Betul, Chhindwara, Seoni and Mandla and the uplands of Balaghat. South of the Satpuras are the three great plains of Berar, Nagpur and Chhattisgarh, all bounded by hills on the south, Chhattisgarh being divided from the rest of the state by the Maikal range.

The state is bounded on the east by the states of Behar and Orissa, on the southeast by Madras, on the south by Hyderabad, on the west by Bombay, Madhya Bharat (formerly western districts of the Central India agency) and Bhopal, and on the north by Vindhya Pradesh (former eastern Central India) and Uttar Pradesh (former United Provinces).

Only the two Vindhyan districts drain into the Gangetic plain. The waters of the rest of the northern districts and west Berar are carried by the Nerbudda and the Tapti, fed by their many tributaries rising in the Satpuras, into the Arabian sea. South Berar and the Nagpur division drain southeastward into the Godavari, the principal rivers being the Waingunga, the Wardha, the Painganga and their numerous tributaries. The eastern and southeastern portion, Chhattisgarh, is drained by the Mahanadi to the Bay of Bengal. Except for short reaches none of these rivers is navigable throughout the year.

Climate.—In climate the Vindhyan and Satpura districts are comparatively temperate; the Nerbudda valley is not, and the three great plains south of the Satpuras have the temperature of the Deccan, the heat from March to the middle of June being excessive, but very dry. The three northern tracts enjoy a pleasant cold season; in the three southern ones the cold is limited to occasional snaps, and the season is cool rather than cold. But, except in the extreme south of Chanda and the tracts nearest Bengal where the rains produce an exceedingly steamy atmosphere, the state has the advantage of a reasonably cool, rainy season, since both the cyclonic storms from the Bay of Bengal and the steady current of the southwest monsoon from the Arabian sea bring it moisture-laden clouds. The rainfall varies in the west from 25 to 30 in., and in the east from 50 to 60 in. The monsoon period is divided between early rains, often deficient; middle rains, seldom failing completely; and late rains, premature cessation of which frequently causes severe losses. In 1896 the late rains failed completely, and in 1899 all three periods were failures. These caused the most extensive famines in the history of the province since it had come under British rule. (R. H. C.; B. R. P.)

HISTORY

The two territories forming the greater part of the present state have a somewhat different history. The history of Berar is mainly the history of the Deccan, to which it geographically belongs. The Central Provinces were known to the races of the north as the "Forests of the South," inhabited by Rakshas or demons, but ancient Rajput dynasties penetrated to the more open parts of the country, and of these the famous Hai Hai Bansi dynasty ruled Chhattisgarh for many centuries until conquered by the Bhonslas in 1741.

The Gonds.—The rest of the Central Provinces were known as Gondwana, the kingdom of the Gonds, who held the wildest parts of the country. The oldest Gond kingdom was that of Chanda in the south, to which a history of about 800 years is sometimes attributed. In the north was the kingdom of Garha-Mandla, from which sprang the two subkingdoms of Deogarh in Chhindwara and Kherla in Betul. This last was overthrown by Hoshang Shah of Malwa, the founder of Hoshangabad. The Gond kings, who must have established their rule over older Rajput dynasties, were fond of describing themselves as Rajgonds, and of claiming a Rajput origin.

One of these Gond kings named Sangramsha, said to have been the 47th of the Garha-Mandla house, in 1480 extended his dominion over the Nerbudda valley and the Vindhyan districts. Sangramsha lived until 1530, but a successor of his, Chandrasha, was forced to cede these territories to the Moguls in 1570. Though these Garha-Mandla chiefs owed a nominal allegiance to the Mogul emperor they maintained a virtual independence until the weakening of the Mogul power let in the predatory forces of the Marathas and (in the north) the Bundela chiefs. The Garha-Mandla raj was finally overthrown by the Peshwa in 1780.

The Gond rajah of Deogarh had paid a visit of homage to Delhi, and was so impressed with what he saw there, that he became a Mohammedan, adopting the name of Bakht Buland and establishing a new capital at Nagpur. He was himself an enlightened chief but one of his grandsons, quarrelling over the succession, invited Raghoji Bhonsla from Berar to help him against his brother.

The Marathas.—Raghoji with his Marathas accomplished this mission and returned to his own territory, but later he established himself at Nagpur. Raghoji I sprung from a peasant family in Satara, was a great leader, and by 1751 had conquered the territories of Nagpur, Chanda and Chhattisgarh. He defied the Peshwa, raided Bengal, and extended his sovereignty over Orissa. He died in 1755 and his son Janoji was forced to submit to the Peshwa, but the next rajah, Mudhoji, and, after him, Raghoji II acquired by purchase the northern territories as well, and the Nagpur state thereafter comprised the whole of the Central Provinces, Orissa and some of the Chota Nagpur states. By joining Sindia against the British in 1803, and as the result of Wellesley's victories of Assaye and Argaon, Raghoji lost Cuttack, Sambalpur and part of Berar. His successor, Mudhoji (known as Appa Sahib), by a treacherous attack on the British in 1818, was forced to cede the whole of the northern districts. Appa Sahib was allowed to hold the Nagpur territory, but on his further treachery being discovered he fled, and an infant grandson of Raghoji II was recognized as rajah by the British government. During his minority the Nagpur territories were administered by the British resident until 1840. The raja Raghoji III died in 1853 without male issue, and Lord Dalhousie declared the Nagpur state an escheat.

Central Provinces Under British Rule.—The northern territories ceded in 1818 and known as the Saugor Nerbudda territories were administered as part of the province of Agra. When the Nagpur territories escheated in 1853, they were administered by a commissioner as the Nagpur province. In 1861 they were

amalgamated with the northern territories and became the Central Provinces. In 1903, Berar was added to the charge of the chief commissioner. In 1905, on the partition of Bengal, the Sambalpur district and the Oriya states adjacent to it were transferred to Bengal in exchange for five Hindi-speaking states of Chota Nagpur.

The first chief commissioner was the energetic Sir Richard Temple. His successor, Sir John Morris, governed the province for over 15 years, after which came a rapid succession of chief commissioners. The pioneer work of Sir Richard Temple and Sir John Morris, aided by a commission consisting mainly of military officers, provided the province with several important trunk roads and with a land settlement on the zamindari system. The Tenancy act of 1883 gave the tenantry of the province a degree of security in their holdings which no other zamindari province in India enjoyed to a like extent. The land settlements then made were afterward twice revised under a system which will always be associated with the name of Sir Bampfylde Fuller.

The first railway was opened in 1870, and the railway system of the present day extends to nearly 2,000 mi. The two trunk railways between Bombay and Calcutta pass through the north and south of the province respectively. The Marathi-speaking districts in the south and west are more advanced than the Hindi-speaking districts of the north and east.

There were serious setbacks; disastrous famines occurred in 1867, 1897 and 1900, while there were serious crop failures in 1907, 1913, 1918, and 1920, which would have produced similar results but for the vastly improved protection afforded by the increased credit and prosperity of the people. Plague has also taken its toll of the large towns, the worst epidemics known having been in 1903 and 1909. The influenza outbreak of 1918–19 accounted for about 950,000 deaths.

Following the implementation of the Government of India act, 1935, the province was constituted autonomous on April 1, 1937, and in that year came under the rule of a popularly elected Congress party ministry.

History of Berar.—The fertile plain of Berar (the ancient Vidharba) had a chequered history. It was under the sway of the various dynasties that ruled southern India until the Mohammedan invasion at the end of the 13th century, when it formed a province of the Bahmani dynasty, but about 1490 a rebellious governor, Imadul-Mulk, declared his independence and established a kingdom, which was again wrested from his descendants in 1572 by the Ahmednagar king. It was ceded by him to the Moguls in 1595, when his own capital was besieged by them, and the emperor Akbar's sons governed it together with Ahmednagar and Khandesh until Akbar's death in 1605. It then came under the rule of Malik Ambar the Abyssinian. On his death in 1626, the emperor Shah Jehan once more annexed it.

Toward the end of the 17th century, when Mogul power was waning, Berar began to be overrun by the Marathas, who won from Delhi their claim to blackmail (*chunth*). In 1724 Nizam Asaf Jah, establishing the independent line of nizams of Hyderabad, laid claim to Berar. This claim was disputed by the Bhonsla rajahs, and for about 50 years the inhabitants were harried and ground down by this conflict of authorities. This was ended by Wellesley's victories of Assaye and Argaon in 1803, when the country west of the Wardha river was ceded to the nizam.

Pindari and Bhil raiders, and also the exactions of their disputing rulers, harried the people. The nizam pledged the revenues as security for loans taken by him, the result being further exactions from the tax farmers to whom the revenues had been assigned. The British at last intervened in 1853, and a treaty was made with the nizam by which these territories came under British administration under the title of the Hyderabad assigned districts. On the subject of boundaries this treaty was again revised in 1860, and it was agreed that the British government should administer Berar in trust for the nizam, to whom was given the balance of the revenues after the cost of the Hyderabad contingent and of the administration of these districts had been met. Lord Curzon later concluded a fresh treaty with the nizam whereby the latter agreed to give a perpetual lease of these districts to the British government in return for an annual payment of 25 lakhs of rupees.

The six districts of Berar were reduced to four and a commissioner's division attached to the Central Provinces, but the sovereign rights of the nizam continued. By an agreement dated Oct. 24, 1936, the king-emperor reaffirmed the nizam's sovereignty over Berar, and the nizam agreed to Berar and the Central Provinces being administered together as one province.

Berar, after centuries of harassment, became a peaceful and prosperous subprovince, made wealthy by the cotton crop and cotton industry, and cultivated by as prosperous a tenantry as could be found anywhere in India outside the most highly irrigated tracts. The revenue settlements of Berar are ryotwari, namely, made with the peasantry direct.

The system follows generally that of the adjacent districts of Bombay, and village headmen in Berar perform, for a percentage remuneration on the revenue they collect, duties which in the Central Provinces proper were assigned to the malguzars, or village proprietors. After the institution of the republic the Madhya Pradesh legislature passed measures to extend the ryotwari system to the whole state. (R. H. C.; C. C. D.)

POPULATION

Nearly one-fifth of the people are of aboriginal and old Dravidian races, Gonds being the most numerous. Most of the rest are immigrants, mainly Hindus, who entered either in very ancient days or else intermittently (notably when the Moguls conquered the Deccan and exercised suzerainty over the Gond chiefs). Many of these came from Malwa, some from Hindustan, but with the entry of the Marathas on the scene in the 18th century, a large influx of Marathi-speaking people poured in from the west. On the fringes along the east and south there are Oriya and Telugu immigrants. Moslems numbering about 3.6% of the population are to be found mainly in the towns, being descendants of settlers who clustered around Mogul posts and certain seats of government, or such special cities as Burhanpur and Ellichpur. Individual Moslem families occupied land in the interior, but while only 12.45% of the total population is urban about 40% of the Moslems live in the towns.

With such heterogeneous elements and origins, there are great diversities of language. There are ten major languages, with many separate dialects of the same. Hindi is spoken by 56% of the population, Marathi by 31% and Gondi by 7%. About 200,000 people are returned as speaking many minor languages.

The first regular census was taken in the Central Provinces in 1872, in Berar a few years earlier. The figures of that census may be taken as representing the high-water mark of development before railways entered the province. The contrast provided by the 1941 census is notable.

	Population 1872	Population 1941 census
C. P. · British districts.	7,723,535	13,208,718
Berar	2,427,654	3,604,866
Feudatory states	928,195	4,064,000
	10,879,384	20,877,584

This increase was shown in spite of a decrease during the decade 1891–1901 caused by the great famines and the first ravages of plague, and virtual stagnation in the decade 1911–1921 which included World War I, two serious crop failures, and the great influenza scourge of 1918–19.

The state made strides educationally. Colleges and high schools and subsidiary institutions multiplied in numbers, and there is a teaching and affiliating university with headquarters at Nagpur, founded in 1923, and another centred upon Saugor, founded in 1946. In the 40 years between 1881 and 1921 literacy among males increased from 51 to 103 per thousand, and among females from 1 to 8 per thousand; in 1941 the coresponding figures were 196 per thousand and 48 per thousand. In 1921, 84 per 10,000, or under 1% of the males could read English, but only 9 per 10,000 females, or under 1 per thousand; by 1941, 161 per 10,000 males and 24 per 10,000 females could read English. Great ef-

forts were made to extend medical relief in hospitals and dispensaries, better knowledge of hygiene and child welfare. The public revenue reflected the general advancement; in 1926–27 it was 534 lakhs of rupees, and in 1947–48 it was 1,224 lakhs.

ECONOMICS

The trade of the country increased greatly, the value of the rail-borne traffic being about 60 crores of rupees annually. The bulk of the exports are cotton, wheat, rice, oil seeds and other agricultural produce, but coal and manganese are now important items. Coal is unfortunately of too poor a quality to be of any use for metallurgical purposes. There are coal fields in Narsinghpur, Chanda and Wun (Berar), and in the Pench valley in Chhindwara (*q.v.*). It is used in cotton mills and factories and to some extent on the railways. The manganese deposits in Nagpur, Bhandara, Balaghat and Chhindwara are being vigorously worked and about 500,000 tons a year are produced. There are plentiful bauxite deposits in Jubbulpore and Balaghat awaiting exploitation. Iron ore is found in many districts, but worked only by indigenous methods in small charcoal furnaces. There are large deposits of excellent ore in Chanda, but for want of coking coal it is practically untouched. There is also valuable limestone in many places, notably near Katni, where lime and cement works are important industries.

There were 1,217 factories of all kinds in the Central Provinces and Berar in 1945, together employing more than 110,000 persons. However, outside the cotton industry the gun-carriage factory in Jubbulpore and the government and railway workshops, organized manufacturing industries are confined mostly to small concerns scattered about in various districts, but the motor trade and electrical installations are increasing. Rural and small hand industries include hand weaving, the manufacture of brass and copper utensils, pottery, shoes, baskets, bamboo matting, carpentry and smithy work, but the larger colonies of handicraftsmen have suffered from the competition of machine-made goods, both local and imported. In the mass, however, cottage and hand industries still have a large output. They depend on agricultural prosperity and suffer with agriculture from the effects of bad seasons.

Agriculture.—A line drawn from Katni in the north to Chanda in the south roughly divides the agriculture of the country. East of that line the principal crop is rice, and the rainfall is heavy. West of it, there are two sections the northern in which wheat, gram and cold-weather crops are the most important; the southern in which cotton and *jawari* or great millet (sorghum) are the important staples. The Nerbudda valley and the Vindhyan districts are the large wheat-producing areas; Nimar, Berar and Nagpur (west), mainly composed of Deccan trap, are the great cotton and *jawari* tracts; but while cotton and *jawari* are quite insignificant in the rice country, and rice is insignificant west of the line of division described, practically every district in the state contains some heavy black soil areas which produce wheat and cold weather crops. This variety of soil and cropping affords a certain degree of insurance against capricious rainfall. There are nearly 6,000,000 ac. of rice, 3,500,000 ac. of wheat, 4,750,000 ac. of *jawari* millet and 3,250,000 ac. of cotton. Besides these, there are large areas under oil seeds—linseed, sesamum and niger being the most important. There are pulses and peas of many kinds, and in the hills and light soils, small millet (*kodo* and *kutki*), the staple food of the aboriginal tribes.

In Berar the system of land revenue settlement is the ryotwari system, on the Bombay model. In the Central Provinces proper the proprietary system of Agra formerly prevailed, but the Central Provinces tenant enjoyed by law and tradition a degree of protection greater than in any proprietary province, and with this security against arbitrary ejectment and arbitrary enhancement of rent, he thrived in spite of fluctuations caused by bad seasons and resulting debts. In 1951, however, the Madhya Pradesh legislative assembly enacted measures extending the ryotwari system to the former Central Provinces divisions. Much was accomplished by the creation and expansion of the agricultural department from small beginnings to a well-regulated service with experimental seed and demonstration farms, model cattle farms, scientific research and education to improve the yields and better the lot of the cultivator, while co-operative banks and societies spread all over the country, affording cheaper credit than the moneylender would offer.

In the rice districts there are numerous irrigation works made by the people themselves, though few of these can stand against protracted drought. Government irrigation works only began to be undertaken after the report of the irrigation commission in 1903; important irrigation works, including the Wainganga, Tandula, Mahanadi, Kharung and Maniari canals, were later undertaken at a cost of more than 7 crores of rupees. By the 1950s these protected 500,000 ac. from the effects of drought. There were still several large projects under construction and investigation, principally in the Bilaspur district, which had been somewhat neglected in this respect. The area of government reserved forests in 1948–49 was 19,414 sq.mi.; there were also about 9,000 sq.mi. of private woods. On the absorption of the feudatory states into the province 7,455 sq.mi. of reserved forests and 10,464 sq.mi. of other forests were added. There are valuable sal (*Shorea robusta*) forests in the northeast, and teak (*Tektona grandis*) in almost every district, though teak of fine girth is limited to a few well-known reserves. There are many miscellaneous kinds of timber, bamboos and minor produce of commercial value, while there are edible fruits and roots with which the forest tribes supplement their food supply. The mohua tree (*Bassia latifolia*) has a flower which is edible, and from which country liquor is distilled, as well as a nut from which oil is extracted. The government forests yielded in 1947–48 a revenue of about 152 lakhs of rupees.

Communications.—Before the railways, there was a burst of activity in the construction of some important trunk roads, some of which were allowed to fall into disrepair when the trunk lines of railways were built. A branch of the East Indian railway from Allahabad to Jubbulpore was the first railway constructed in the province in 1870, while the G.I.P., bifurcating at Bhusawal, in Khandesh, sent one line to meet the East Indian at Jubbulpore, and a second branch through Berar to Nagpur. It was 20 years before the Bengal-Nagpur railway, absorbing a state metre-gauge line from Nagpur to the borders of Chhattisgarh (opened in 1881) made a second connection between Bombay and Calcutta via Nagpur and Bilaspur, from which place a branch went over the Ghats and across Rewa state to join the East Indian at Katni. The Indian Midland railway, afterward amalgamated with the G.I.P., made a fresh connection from Itarsi in Hoshangabad, via Bhopal, Gwalior and Jhansi, with Agra and Delhi, and a branch from Bina, through Saugor and Damoh, connecting with Katni followed a few years later. The turn of the century saw the next development by the Bengal Nagpur railway of narrow-gauge lines (2 ft. 6 in.) across the Satpuras from Gondia in Bhandara to Jubbulpore, with branches to Seoni, Chhindwara and Mandla on the Satpura plateau. This was followed by a line from Gondia southwestward to Chanda where it met an extension of the Warora Coal railway to the new coal field at Ballaspur, a few miles south of Chanda. Connections on the same narrow gauge with this branch to Nagpur and on to Chhindwara followed. A further broad-gauge connection between Nagpur and Itarsi was completed in 1926, crossing the Satpura district of Betul with a branch into the Chhindwara coal field.

Two links were constructed to complete direct broad-gauge connections between southern India and the north, one from Warangal to Chanda, and the other from Vizianagram on the east coast to Raipur One more link on the metre gauge was required to join the Hyderabad Godaveri railway at Hingoli with the Rajputana-Mulwa railway at Khandwa, via Basim and Akola. With this addition, the network of railways in Madhya Pradesh state would be completed, representing a length of 2,800 mi. inside the state. In 1946 there were 2,594 mi of railway (1,741 mi. broad gauge and 853 narrow and metre gauge). There are also feeder lines in the cotton country of Berar and Wardha, controlled by private companies; by the 1950s only a few feeder lines remained to be constructed. In 1946 there were about 18,600 mi. of roads, 5,750 mi. were metalled, 3,100 unmetalled and 9,750 rough forest roads and cart tracks; however, with the great increases of motor traffic which had begun to penetrate even the remoter areas, there was still an enormous scope for road construction.

CENTRAL SCHOOLS. The English central school grew out of the top end of the public elementary school. It had had similar predecessors. Within a few years after the passing of the Elementary Education act, 1870, which established the English national system, some of the larger and more enterprising school boards began to provide schools, centrally situated to serve relatively large districts, which offered more advanced instruction to elementary school children who had successfully completed the work of the normal school. These schools were variously called higher board, higher central, higher elementary or, more often, higher grade schools.

The Cockerton judgment of 1901, which ruled that a school board had no legal right to use its funds to provide education other than elementary in an elementary school, put an end to this movement, and most of the higher grade schools were absorbed into the statutory system of secondary education established by the Education act, 1902. But again, within a few years some of the local education authorities (which had replaced the school boards in 1902) began to experiment with the provision of separate

schools for the abler among the older elementary school pupils. By about 1905 the London County council had established at least one central school, and Manchester was making similar experiments. It was from this movement that the central school proper developed.

In 1911 the London County council established a system of central schools throughout its area. Its declared purpose was to prepare boys and girls for immediate employment on leaving school, and its essential features were (1) entry at 11–12 years, from elementary schools; (2) a 4-year course; *i.e.*, one extending a year beyond the minimum leaving age; (3) a technical or commercial bias (or both) to the curriculum. Entry was either by recommendation of an inspector or head teacher or, more usually, by examination; places being offered to pupils who narrowly failed to gain entry to the council's secondary schools.

In 1912 Manchester established six district central schools on similar lines, and after World War I many other local authorities followed suit. Not all were so selective of pupils as London and Manchester. During the 1920s three types of central schools developed: (1) those in which pupils were selected, usually by examination, at the entry age of 11; (2) those to which children of 11 years and over were admitted on the request of their parents, supported by the recommendation of their head teacher; (3) those into which all the children in a given district who did not enter secondary school were collected. The first type was known as the selective central school, and the third type as the nonselective.

Nonselective central schools normally gave a general post-primary education which often included a considerable amount of practical work in art and handcrafts. Selective central schools tended increasingly during the first two years to give a general education, including usually one foreign language, and thereafter one or more courses with a definite bias, engineering being the most usual for boys and domestic science for girls. Some schools, however, emulated the recognized secondary (grammar) schools, providing an academic curriculum and presenting pupils for the school certificate examination.

In 1926 the consultative committee of the board of education, in their report on *The Education of the Adolescent* (the Hadow report), recommended that both selective and nonselective central schools should have secondary status, under the name of modern schools. This recommendation was not adopted, but in accordance with another recommendation local authorities began to reorganize their elementary schools into junior and senior schools with separate premises; and this, with other causes, tended to sharpen the distinction between the selective and nonselective schools, the latter frequently being called senior schools and tending to depart farther from the traditional academic curriculum, whereas the selective schools tended to become more academic.

The central school disappeared from the English educational system on the passing of the Education act, 1944, when all post-primary schools received secondary status. (H. C. D.)

CENTREBOARD or DROP KEEL, a drop board or iron plate employed in the smaller kind of sailing boats in place of a fixed keel, it is housed in a trunk or casing so as to be capable of being lowered through the boat's bottom when required to give stability, or to prevent making leeway in a wind, and can be hoisted in shallow water or when running before the wind.

CENTRIFUGE is commonly defined as a machine using centrifugal force for separating materials of different densities, but has the broader connotation of any machine designed for the specific purpose of subjecting materials to a sustained centrifugal force. Being of essentially the same nature as gravitational force, centrifugal force can be employed to accelerate or greatly accentuate many processes otherwise dependent on the comparatively meagre attraction of gravity. Apparently this fact was early recognized, for it is known that centrifugal machines were used in the 10th century A.D. for extracting tung oil.

Centrifugal Force.—As enunciated by Sir Isaac Newton in his famous laws of force and motion, a freely moving body tends to travel in a straight line, and if directed along a curved path, it will exert a force against the directing or restraining object in its continual effort to "fly off" onto a straight tangent course. For example, it is a familiar observation that an object revolving in a circle exerts a force away from the centre of rotation. Also, there is general appreciation of the fact that the amount of this force can be increased by increasing either the angular velocity of rotation (S), the mass of the object (M) or the radius (R) of the circle through which the object moves. Perhaps not so generally appreciated is the fact that whereas the centrifugal force is directly proportional to the radius and to the mass, it is, as examination of the formula below will show, proportional to the square of the angular velocity. For example, doubling the number of revolutions per minute will increase the centrifugal force by a factor of 4 (equals 2 times 2); increasing the speed by a factor of 10 will increase the force by a factor of 100 (equals 10 times 10). The actual amount of centrifugal force (F), expressed in dynes (1 gram of force = 980 dynes), is given by:

$$F = \frac{\pi^2 S^2 MR}{900}$$

where S is in revolutions per minute, M is in grams and R is in centimetres.

In order that a clearer concept of the amount of centrifugal force acting on an object may be provided, the force is often compared directly with the weight (pull of gravity) of the object and the amount of force is stated as so many "times gravity" or so many "g's." For example, an object revolving at the rate of 600 r.p.m. in a circle having a radius of 10 cm. (equivalent to 3.94 in.) generates a centrifugal force which is 41 times gravity. Through the use of special research apparatus, forces greater than 5,000,000 times gravity have been produced by spinning small metal rotors of about pea size at speeds exceeding 1,000,000 r.p.m.

The rotating element of a centrifuge is usually driven about a fixed axis by an electric motor, or by an air turbine in some high-speed machines, and is variously known as a rotor, rotator, bowl, drum or centrifugal. For the minimizing of vibration and strain on the shaft and bearings, it is essential that a loaded rotor be well balanced; *i.e.*, that the total mass be so distributed about the axis of rotation that the resultant of all the elemental forces is zero. If the bearings are suited to high speeds and if ample power is available to overcome the frictional resistance of the bearings and the surrounding air, the only limitation to the speed of a well-balanced rotor is the strength against rupture of the material from which it is made. For example, a 15-cm. (6-in. diameter) duralumin rotor used in certain biological studies and designed especially for high speeds has a limiting speed for routine operation of about 60,000 r.p.m. In a rotor of given design, the maximum angular velocity obtainable before rupture is to a close approximation inversely proportional to the rotor's diameter. Thus, a small rotor having only one-half the diameter of a larger one can be as safely rotated at twice the angular velocity and with the production at the periphery of twice the centrifugal force.

Effect on Liquids.—Of special importance is the centrifugal behaviour of liquids, particularly those in which is suspended solid particulate matter of small size or globules of an immiscible fluid; *e.g.*, the suspended particles in a water-oil emulsion. The net force acting on any portion of the liquid is the vector resultant of both the centrifugal force and the force of gravity. However, in general the force of gravity is so small in comparison with the centrifugal force generated during operation that its effect may be neglected in the present discussion of principles. In the centrifugal field of force, the liquid tries to distribute itself as far as possible from the axis of rotation, filling the outer portions of the container and forming a free surface which is everywhere equidistant from the axis and hence cylindrical in shape.

Any suspended particles which are more dense than the suspending liquid tend to migrate toward the periphery, while any having a lower specific gravity move toward the surface. The rapidity with which this migration proceeds is dependent on the intensity of the centrifugal force, the difference between the density of the particle and that of the suspending liquid, the viscosity of the liquid, the size and shape of the particle and to some extent the

concentration of the particles and the degree to which they are electrically charged. The net motivating force exerted on the particle is the difference between the centrifugal force acting on it and the opposing buoyancy of the liquid, the buoyancy being equivalent to the centrifugal force acting on the volume of liquid displaced by the particle. In a steady state of migration, this net motivating force must be equal to the viscous drag of the liquid. For spherical, electrically neutral particles in dilute suspensions this resistance has been shown by G. G. Stokes to be given by the following relationship:

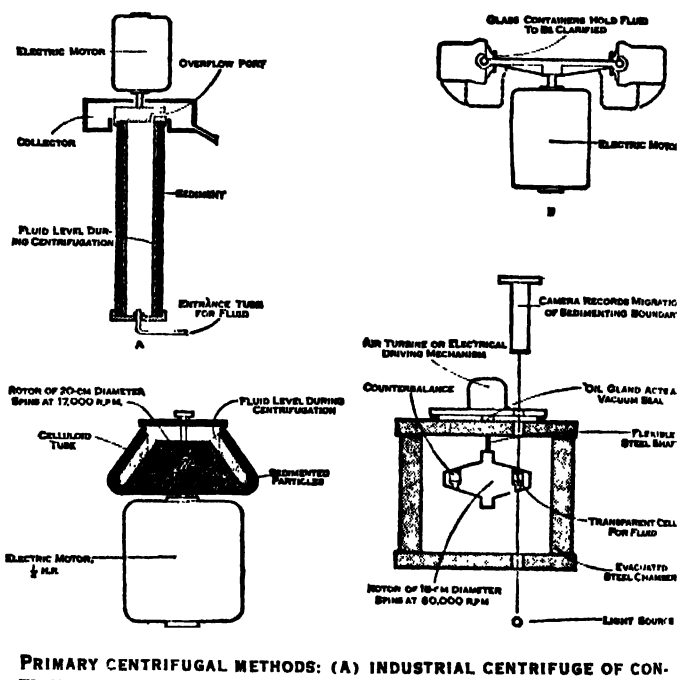
$$f = 6\pi\eta r s$$

where f is the resistance in dynes, η is the viscosity in poises, r is the radius of the particle in centimetres and s is the speed of migration in centimetres per second. Equating the expressions for the resistive and the net motivating forces and solving for s, one finds that the rate of movement is proportional to the square of the particle's radius:

$$s = \frac{\pi^2 S^2 R (\delta - \rho) r^2}{4050\eta}$$

where δ and ρ are the densities of the particle and the suspending fluid respectively. Thus, all other things being equal, a particle having a diameter 10 times that of a given particle will require only 1/100 as much average centrifugal force to move a given distance in a given time. The table, though somewhat oversimplified for the sake of clarity, gives some idea of actual requirements for particles of various sizes, the assumption being made that no remixing occurs within the fluids. Actually, remixing is a definite problem in the centrifugation of small particles at high speeds and is discussed in the next section.

From the foregoing discussion, it is clear that a practically complete separation of the suspending medium and the suspended phase can be produced if the centrifugation is allowed to continue until all particles have collected against the outer wall of the rotor. It should also be noted that a partial separation of two groups of suspended particles of different size can be effected by allowing centrifugation to continue only long enough for all of the larger particles to be completely packed into the sediment, since then many of the small particles will still be suspended in the fluid. If purification of the larger, as well as the smaller particles is desired, the supernatant fluid can be drawn off and the sediment resuspended in some suitable liquid and subsequently centrifuged again to effect further separation. This process may be repeated any number of times.



Industrial Centrifuges.—There are numerous industrial applications of centrifugal force. Thick-walled metal pipe and tubing are cast by pouring the molten metal into cylindrical moulds which are then rotated while the metal sets into the solid state. Perforated rotating drums or baskets are used for extracting fluids from various natural products after crushing, for throwing off the excess water from washed clothes and for retaining sugar crystals while the liquor in which the crystallization took place is drained off under the action of centrifugal force. However, the greatest advantage of the centrifugal method is realized in fractionating fine suspensions of solid or liquid material. The cream separator is a familiar example. Though variously modified to suit the particular application, most machines employed for such purposes are of the continuous-flow type, as illustrated by (A) in the figure. The bowl or rotor, generally cylindrical in shape, is provided with a central opening to permit the continuous introduction of liquid during operation, and with one or more exit ports from which the centrifuged fluid can overflow and be thrown into collectors.

In the simplest type of machine, only one exit port is provided for the supernatant fluid, the sedimented particles being collected in the precipitated form after the rotation has been stopped. In other machines two overflow passages are used, one being at the level of the supernatant fluid and the other leading from the peripheral section of the fluid to an exit port located at a slightly greater radial distance than the overflow for the supernatant fluid. With this arrangement both a "light" fraction (supernatant) and a "heavy" fraction (of increased density because of increased concentration of heavier material or loss of lighter material) of fluid can be continually collected, the flow being kept sufficiently rapid to prevent complete sedimentation of the particles if they are of such a nature as to pack easily into a semisolid sediment.

In many cases, centrifugal bowls are provided with a series of laminations, usually conical in shape and known as separators. Subdividing the fluid into thin layers generally has the effect of speeding up the separating process by reducing the distance through which a particle has to move before its effective removal from the main body of fluid. As soon as a particle reaches the wall of a separator, it can collect with other particles into larger groups that will slide along the wall into the heavy fraction at the periphery, or toward the surface if the particles are of low density. Such an arrangement also minimizes stirring and remixing as the fluid flows through the centrifuge.

Laboratory Centrifuges.—Centrifuges are used extensively in biological and chemical laboratories for the clarification of fluids and for the concentration and purification of various biological and chemical agents.

Most laboratory centrifuges are of the swinging-bucket type (B in figure) or, for work at higher speeds especially, of the inclined-tube type (C in figure).

PRIMARY CENTRIFUGAL METHODS: (A) INDUSTRIAL CENTRIFUGE OF CONTINUOUS FLOW TYPE; (B) LOW-SPEED LABORATORY CENTRIFUGE WITH SWINGING BUCKETS; (C) LABORATORY CENTRIFUGE WITH INCLINED TUBES; (D) OPTICAL ULTRACENTRIFUGE FOR MEASUREMENT OF SEDIMENTATION RATES AND DETERMINATION OF PARTICLE SIZES

Submicroscopic disease agents such as influenza virus, smallpox virus, yellow fever virus and the virus of infantile paralysis are nearly always obtained in the presence of considerable extraneous material of both larger and smaller particle size. They might be found in the excreta, blood or other body fluids of an animal, or they might be recovered from ground extracts of certain tissues such as those of the brain or the lungs. Through the process of differential centrifugation already described, these biological agents can be partially purified for further study or for practical purposes such as the manufacture of vaccines.

Laboratory centrifuges of proper design may be used not only for preparative purposes but for semiquantitative investigation as well. As a matter of fact, such a study in various degrees of refinement is usually a preliminary step in selecting appropriate rotational speeds and centrifugation times for a desired purification procedure. If excessive convective disturbances and remixing within the fluid can be avoided, the approximate size of the sedimenting particles can be computed by determining the minimum time required at a given speed for a definite amount of sedimenta-

tion and applying the previously discussed formula for spherical particles. The method depends on the sampling of the centrifuged column of fluid at various levels and the determination, by specific biological, physical, or chemical tests, of the amount of the respective agent present in each sample. In less quantitative work, almost all of the supernatant fluid may be drawn off into one sample and compared with the sediment after resuspension in fresh fluid.

Two practical difficulties often limit the efficiency of the sedimentation process and make quantitative determinations of sedimentation rate uncertain if not impossible. One involves the remixing caused by the tendency of the fluid to continue revolving as the centrifuge is decelerated to rest. The other involves convection currents caused by slight differences in the temperature of the liquid at different levels, and it is most serious with small particles which require long periods of centrifugation. Since convection is essentially a buoyancy phenomenon, its intensity is stepped up almost directly in proportion to the amount of centrifugal force, and hence convection can be caused by extremely small temperature differences, such as might arise from the difference in the amount of frictional air resistance suffered by a rotor at its periphery and at its centre.

The first difficulty can largely be avoided by using small centrifuge containers and by packing the particles under study into a semisolid sediment before stopping the centrifuge. Air resistance, and hence almost all convection, can be avoided by spinning the rotor within an evacuated chamber according to a method developed by E. G. Pickels and J. W. Beams, illustrated by (D) in the figure.

The elimination of air resistance also makes possible the attaining of high rotational speeds with relatively little expenditure of energy.

The Analytical Ultracentrifuge.—More precise determinations of particle size and weight can be made by centrifuging the suspension in a cell fitted with transparent windows and recording photographically the progress of the sedimentation (*see* D in figure). This method was first used by T. Svedberg and J. B. Nichols in 1923 and was widely applied thereafter to determine the sedimentation rates and sizes of many submicroscopic particles, particularly protein molecules and viruses. Svedberg and H. Rinde proposed for the first optical centrifuge the name "ultracentrifuge," denoting an instrument suitable for quantitative measurement. However, it became general practice to associate the term ultracentrifuge with any type of centrifuge operating at speeds of more than about 20,000 r.p.m.

When all the suspended particles are of the same size, as might be the case with a solution of haemoglobin molecules, for example, the particles within any elemental zone of fluid, and hence within the same field of force, will migrate through the liquid at the same rate. Thus, the particles originally at the inner surface of the fluid will form a "rear line of march," or moving boundary, which demarcates the supernatant fluid and the sedimenting solute. It is by photographic recording of the continually changing position of this boundary at repeated intervals that precise determinations of sedimentation rate are made. From the sedimentation rate, in turn, the size or molecular weight of the particles can be determined if the shape factor is eliminated by a measurement of the diffusion constant. If particle groups of differing size are present, each group will form a separate boundary which sediments at a rate characteristic of the particle size. From a study of such multiple boundaries, the composition (from the standpoint of size) of the suspended matter in various biological fluids can be determined and reinvestigated following various treatments.

Migrating boundaries may be detected either through the absorption of visible or ultra-violet light by the sedimenting particles or through the refraction of transmitted light occasioned by the concentration gradient existing at the boundary. The first ultracentrifuges to operate at more than 50,000 r.p.m. were driven by an oil turbine about a horizontal axis in a hydrogen atmosphere at reduced pressure. As illustrated in the figure, most ultracentrifugal rotors are spun in an evacuated chamber about a vertical axis, and power is supplied by an air turbine or a special electric motor. For supporting the load at high speeds with a minimum of frictional resistance, successful use has been made of air bearings, magnetic bearings and mechanical bearings of novel design.

The rotor is connected to the driving mechanism through a flexible steel shaft, about $\frac{1}{8}$ in. in diameter, which permits a limited degree of self-balancing.

Following World War II, electrically-driven ultracentrifuges operating at speeds up to 60,000 r.p.m. became available for both analytical and preparative purposes in biochemical and other research laboratories. The serum proteins and other naturally-occurring macromolecules were subjected to extensive study. Through refinements the analytical method was made applicable in certain cases even to small molecules of simple chemical structure. This was accomplished through a layering of clear solvent above the solution during acceleration of the ultracentrifuge. An initially sharp sedimentation boundary was thus formed away from the meniscus and its rate measured in spite of the slow sedimentation and rapid diffusion, which otherwise would prevent the formation of a measurable boundary by such small particles.

*Sedimentation of Spherical Particles Suspended in Aqueous Media**

Assumed diameter of particle, in cm. (1 cm. = 0.39 in.)	Examples of particles in size range of same order	Average centrifugal force necessary to produce sedimentation of 1 cm. in 10 min., expressed as number times gravity	Approx. no. of r.p.m. required, assuming average distance of liquid from axis of rotation to be 10 cm.
1/1,000 . . .	Red blood cells	1.8	120
1/10,000 . . .	Typhus rickettsia	180	1,200
1/100,000 . . .	Influenza virus	18,000	12,000
1/1,000,000 . .	Protein molecules	1,800,000	120,000†

*Assuming viscosity equal to that of water, specific gravity of medium equal to 1 and the average specific gravity of particles equal to 1.3 (order of magnitude for many biological materials).

†Because of the limited strength of materials, speeds above approximately 50,000 r.p.m. are not feasible with rotors of the assumed size. At this speed, an hour or more would be required to produce the indicated sedimentation of animal proteins.

See T. Svedberg and K. O. Pedersen, *The Ultracentrifuge* (1940); E. G. Pickels, "Ultracentrifugation," *Methods in Medical Research* (1952). (E. G. P.)

CENTUMVIRI, an ancient court of civil jurisdiction at Rome. The word is derived from *centum*, hundred, and *vir*, man. The antiquity of the court is attested by the symbol and formula used in its procedure, the lance (*hasta*) as the sign of true ownership, the oath (*sacramentum*), the ancient formula for recovery of property or assertion of liberty. Its concern was with matters of debt and of the property of which account was taken at the census. The *centumviri* were never regarded as magistrates, but as *judices*, and as such would be appointed for a fixed term of service by the magistrate, probably by the *praetor urbanus*. But in Cicero's time they were elected by the *Comitia Tributa*. They then numbered 105. Their original number is uncertain. It was increased by Augustus and in Pliny's time had reached 180. The office was probably open in quite early times to both patricians and plebeians.

BIBLIOGRAPHY.—A. H. J. Greenidge, *Legal Procedure of Cicero's Time*, pp. 40 ff., 58 ff., 182 ff., 264 (1901); J. E. Sandys, *Companion to Latin Studies*, with useful bibliography (1921).

CENTURION (Lat. *centurio*), in the ancient Roman army, an officer in command of a *centuria*, originally a body of a hundred infantry, later the sixtieth part of the normal legion. There were, therefore, in the legion 60 centurions, who, though theoretically subordinate to the six military tribunes, were the actual working officers of the legion. For the most part the centurions were promoted from the ranks: they were arranged in a complicated order of seniority; the senior centurion of the legion (*primus pilus*) was an officer of very high importance. Besides commanding the centuries of the legion, centurions were "seconded" for various kinds of special service; *e.g.*, for staff employment, the command of auxiliaries. (*See* ROMAN ARMY.)

See also J. E. Sandys, *Companion to Latin Studies*, sec. 752 (1921).

CENTURIPE, a town of Sicily, province of Catania, 2,380 ft. above sea level, 7 mi. N. of the railway station of Catenanuova-

Centuripe, which is 28 mi. W. from Catania. It was formerly called Centorbi (anc. Κεντόριπα) or Centuripae. Pop. (1936) 9,255 (town); 10,802 (commune). Thucydides called it a Sicel city; it allied itself with Athens against Syracuse, and remained independent (apart from Agathocles' domination) till the first Punic War. Cicero, perhaps exaggerating, called it the largest and richest city in Sicily, with 10,000 inhabitants cultivating a large territory. It appears to have suffered much in the war against Sextus Pompeius, and not to have regained its former prosperity under the empire. Frederick II. partly destroyed it in 1233, and its ruin was completed by Charles of Anjou. Considerable remains of buildings, including Hellenistic houses with wall paintings, thermal establishments and cisterns, and a number of substruction walls on the steep slopes, mostly of the Roman period, still exist; Hellenistic *terra-cottas* and finely painted vases, both of local manufacture, have been discovered, and a large number of tombs have been excavated. It is surrounded by deep ravines, due to erosion.

See G. Libertini, *Centuripe* (Catania, 1926).

CENTURY, the name for a unit (*centuria*) in the Roman army, originally amounting to 100 men, and for one of the divisions into which the Roman people was separated for voting purposes (*see* COMITIA). The word is applied more particularly to a period of 100 years. The "century-plant" is a name given to the agave (*q.v.*), or American aloe, from the supposition that it flowers once only in every 100 years.

CEOS, an island in the Aegean sea (Gr. Κέως mod. ZEA or KEA), 14 mi. off the coast of Attica, in the group of the Cyclades and the eparchy of Syra. Its greatest length is about 15 mi. and its breadth about 8 mi. Mount Elias in the centre is 1,864 ft. high. Among its productions are lemons, citrons, olives, wine, honey and valonia. There were formerly four towns in the island: Iulis, about 3 mi. from the northwest shore, represented by the town of Kea, Coressia, the harbour of Iulis, Carthaea, in the southeast, at S'tais Polais village; and Poieëssa, in the southwest. Iulis was the birthplace of the lyric poets Simonides and Bacchylides, the philosophers Prodicus and Ariston and the physician Erasistratus. From its excellent code, the title of Cean Laws passed into a proverb. One of them forbade a citizen to protract his life beyond 60 years. Ceos fought on the Greek side at Artemisium and Salamis; joined the Delian league, and also the Athenian alliance in 377 B.C.; revolted in 363–362, but was reduced again. Athens then assumed monopoly of the ruddle, or red earth, the most valuable product of the island. Ceos was divided in A.D. 1207 among four Italian adventurers; was included in the duchy of Naxos in 1537; passed under Turkish rule in 1566 and thence into the Greek kingdom; in 1941 it was occupied by German troops. Silver coins of Carthaea and Coressia date from the 6th century B.C. *See* Pridik, *De Cei Insulae rebus* (1892).

CEPHALIC INDEX, the percentage of breadth to length in any skull. The longer diameter of a skull, the antero-posterior diameter, is taken as 100; if the shorter or transverse diameter exceeds 80 the skull is broad (brachycephalic), if between 80 and 75 it is mesaticephalic, and if below 75 dolichocephalic (*see* RACES OF MANKIND).

CEPHALONIA, largest of the Ionian Islands on the west of the Greek mainland (Ital. *Cefalonia;* ancient and modern official Greek *Kephallenia,* Κεφαλληνία). Pop. (1951) 47,369. Its length is 31 mi. and its breadth varies from about 20 mi. in the southern portion to less than 3 mi. in the promontory opposite Ithaca. The whole island is mountainous, the main range running from northwest to southeast. The ancient Mt. Aenos, now Elato or Monte Negro (5,315 ft.), frequently has snow for several months. There are few permanent streams except the Rakli, and springs are likely to fail in dry summers. In the west a gulf runs up from the south, a distance of about 7 mi.; on its east side is the chief town Argostoli (*q.v.*) (Argostolion), and on its west the rival city of Lexourion. About a mile west of Argostoli, a stream of sea water running into a chasm in the shore is made to operate "sea mills." About 5 mi. from Argostoli is the Venetian castle of St. George. The ruins of Crane are close to Argostoli, those of Pale to Lexourion. On the other side of the island the remains of Same are on the bay of the same name, those of Proni, or Pronni, farther south above the vale of Rakli. All these have impressive walls, Cyclopean and Hellenic. Near the village of Scala is a nameless site with Roman baths and tessellated pavements, a brick temple and rock tombs. The inhabitants of Cephalonia have always been industrious in the construction of cultivation terraces. But only a small proportion of the soil is under cultivation, and the grain production meagre. The chief crop is the currant, in which Cephalonia surpasses Zante. The fruit is smaller than that of the Morea, and has a peculiar flavour; it ordinarily finds a market in the Netherlands, Belgium and Germany. The grape vine also is grown, for wine. The olive crop is of importance, and cotton is grown in the low grounds. Manufactures are few: lace from aloe fibre, Turkey carpets and basket work in the villages; and boatbuilding at both the principal towns. Of all the seven "Ionian Islands" Cephalonia and Zante (*q.v.*) are most purely Greek.

History.—In the Homeric poems the Cephallenes are subjects of Ulysses, but Cephallenia is not mentioned: probably it is represented by Same (*see,* however, under ITHACA). In the Persian War the island took but little part; in the Peloponnesian it sided with the Athenians. The town of Pale supported the Aetolian cause and was vainly besieged by Philip V. of Macedon in 218 B.C. In 189 B.C. all the cities surrendered to the Romans, but Same afterwards revolted, and was reduced only after a siege of four months. The island was presented by Hadrian to Athens, but it appears again later as "free and autonomous." After the division of the Roman empire, it was attached to Byzantium till 1082, when it was captured by Robert Guiscard, who died, however, during the revolt of 1085. In 1204 it was assigned to Gaius, prince of Tarentum, who accepted the protection of Venice in 1215; and after 1225 it was held with Santa Maura and Zante by the Tocco family at Naples. Formally made over to Venice in 1350 by the prince of Tarentum, it fell to the Turks from 1479 to 1500, but Venice held it again till the fall of the republic.

For some time it was administered for the French government, but in 1809 it was taken by the British. Under vigorous governors, like Major de Bosset (1809–13) and Sir Charles Napier (1818–1827), the island advanced in material prosperity, but was several times the scene of political disturbances. It retained longer than the sister islands traces of feudal influence exerted by the landed proprietors, but has been gradually becoming more democratic. Under the Venetians it was divided into eight districts, and an elaborate system of police was in force; after its annexation to Greece it was broken up into twenty demarchies, each with its separate jurisdiction and revenues, and the police system was abolished. In 1941 it was occupied by Italy.

BIBLIOGRAPHY.—A special treatise on the antiquities of Cephalonia was written by Petrus Maurocenus. *See* Holland's *Travels* (1815); Ansted's *Ionian Islands* (1863); Viscount Kirkwall's *Four Years in Ionian Islands* (1864); Wiebel's *Die Insel Kephalonia;* parliamentary papers. CEPHALOPODA, a group of highly organized invertebrate animals of exclusively marine distribution constituting a class of the phylum Mollusca. Some 150 genera of living cephalopods are known, of which the octopus, the squid and the cuttlefish (*qq.v.*) are the most familiar representatives. The extinct forms, however, outnumber the living, the class having attained very great diversity in late Palaeozoic and Mesozoic times. Of extinct cephalopods the Ammonites (*q.v.*) and Belemnites are the most familiar examples.

The Cephalopoda agree with the rest of the Mollusca in general structure and appear to have the closest affinity with the Gastropoda (snails, periwinkles, limpets, etc.). They have a more or less elongate body (visceral mass) covered by a "mantle." The latter secretes a shell and encloses a cavity in which the gills are suspended. The alimentary canal is furnished with the characteristic molluscan rasping tongue or radula. These animals differ from the rest of the Mollusca primarily in that the head and foot are approximated, so that the mouth is situated in the middle of the foot, and the edges of the latter are drawn out into a number

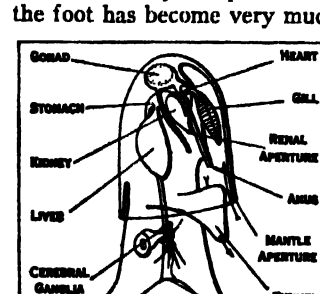
of appendages (arms and tentacles). The area just above the edge of the foot, from which the epipodium of the Gastropoda is developed, is produced to form a peculiar organ of locomotion, the funnel. The majority of living cephalopods possess fins and their shell is in a reduced or degenerate condition, a tendency apparent in many fossil forms. In short the leading feature of cephalopod organization and the dominating theme of their evolution is the development of organs that subserve a vigorous aggressive mode of life unhampered by the heavy calcareous shell that is carried by their more sedentary and inactive relatives. Nevertheless the living *Nautilus* (*q.v.*) and many forms now extinct retain the shell in a complete condition.

(QUARTERLY JOURNAL OF MICROSCOPICAL SCIENCE)
FIG. 1.—NAUTILUS POMPILIUS (ABOUT 1/12 NATURAL SIZE)

For invertebrate animals the Cephalopoda attain a large average size and the genus *Architeuthis* (giant squids) are actually the largest living invertebrates, the Atlantic species *Architeuthis princeps* attaining a total length of 52ft. (inclusive of the tentacles). The shell of the fossil ammonite (*Pachydiscus seppenradensis*) from Westphalia (Cretaceous) measures 6ft. 8in. in diameter and is the largest shelled mollusc. Though not such a flourishing group as they were in secondary times, the Cephalopoda are still one of the dominating groups of marine animals. They are the principal prey of whales and other marine carnivora and the relentless enemies of Crustacea and small fishes. The bizarre appearance of Cephalopoda, their sinister eyes and the secretive habits of some of the shore-living forms have made them a subject of legend among imaginative peoples. Modern authors have not hesitated to exaggerate the horrors of the attack of a giant squid or octopus; and Denis de Montfort and Victor Hugo have invested them with a melodramatic violence that has taken root in popular fancy. Nor is this reputation for ferocity unmerited, as far as attacks on human subjects are concerned.

Classification.—In the past decade the classification of the Cephalopoda has undergone a considerable amount of revision principally owing to the work of Naef and other German zoologists. The following is the scheme drawn up by Grimpe (1922):

Class. Cephalopoda.
- Sub class 1. Protocephalopoda.
  - Order 1. Nautiloidea.
  - Order 2. Ammonoidea.
- Sub class 2. Metacephalopoda.
  - Order 1. Octopoda.
    - Sub order 1. Cirrata.
    - Sub order 2. Palaeoctopoda.
    - Sub order 3. Incirrata.
  - Order 2. Decapoda.
    - Sub order 1. Sepioidea.
    - Sub order 2. Teuthoidea.
    - Sub order 3. Belemnoidea.



It will be seen that this scheme recognizes the fundamental distinction proposed by Owen, which separates *Nautilus* and its allies from the octopods, squids and cuttlefish. This distinction is without doubt sound, for it rests on the fact that, within the limits of our knowledge, the *Nautilus* has a more primitive organization than the rest of the Cephalopoda. It has a wholly external coiled shell, four gills and kidneys, and other features which we are justly entitled to regard as primitive. It must, however, be recognized that we can deal only with the shell of the extinct nautiloids and the ammonites and we do not know if the rest of their organization was like that of *Nautilus*. It is a fair inference, however, that the living and fossil nautiloids and the ammonoids are a natural group. Grimpe's scheme differs herein from the older classification in raising the main sub-divisions to the status of sub-classes and in thus emphasizing their distinctness as is done in the case of the streptoneurous and euthyneurous gastropods. This is an advantage and may be safely adopted.

The classification of the Dibranchia proposed by Naef and Grimpe involves a more fundamental change. In its primary division into Octopoda and Decapoda it follows traditional lines. In its secondary division of these groups, however, it departs from the latter for reasons which appear to us well-founded. Among the Octopoda the fossil *Palaeoctopus* merits recognition as representing a separate sub-order. It is, however, in the reorganization of the Decapoda that the new scheme has most to recommend it. The recognition of the three sub-orders Sepioidea, Teuthoidea and Belemnoidea has the advantage of taking into account our knowledge of the phylogeny of the order, and marking the three great tendencies that can be recognized in the evolution of the decapod shell. The older "Oigopsida" are, as far as nearly all their living representatives are concerned, preserved intact. But the Belemnite-like fossil forms are quite reasonably abstracted from them and placed in a separate sub-order. The older "Myopsida," which contained forms with radically dissimilar shells, such as *Sepia* and *Loligo*, are resolved into two sections, one of which (*Sepia, Sepiola, Spirula* and certain extinct forms) is elevated to sub-ordinal rank (the *Sepioidea*), while the other (*Loligo*, etc.) is treated as a section of the Teuthoidea along with the Oigopsida (as above restricted). It may be reasonably objected that this has the effect of placing forms such as *Sepiola* which, like *Loligo*, have a chitinous, non-calcified shell in a different sub-order from *Loligo* and the Oigopsida, and of disregarding certain points of similarity between the *Loliginidae* and *Sepiidae*. Nevertheless it is held that in spite of this fact, *Sepiola* and its allies are more closely allied anatomically to *Spirula*, which has the distinction of being the only living dibranch with a coiled and partly external calcareous shell, than to *Loligo* and the Oigopsida, and that phylogenetically they can thus be attached to the sepioid stock. Concerning the affinities of *Spirula*, a good deal of controversy has taken place. It seems best to accept Chun's view that it is a sepioid form, as the reasons set forth at length by him in his study of this interesting genus (*Wissenschaftliche Ergebnisse der Deutschen Tiefsee Expedn.* Bd. 18, 1915) are sufficiently convincing.

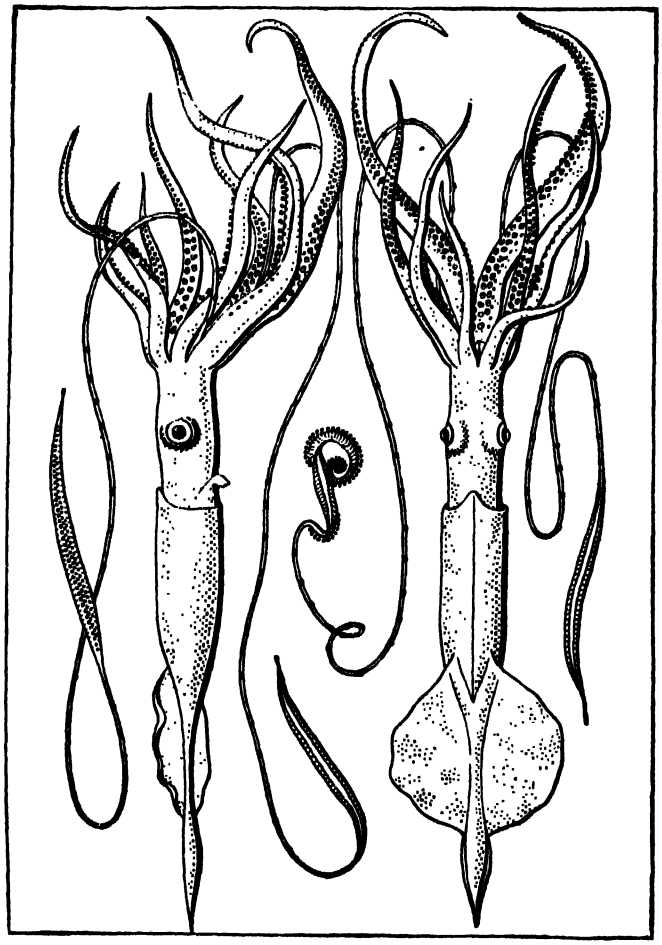
FIG. 2.—AN OCTOPUS RESTING ON THE SEA BOTTOM (ABOUT 1/10 NATURAL SIZE)

Anatomy and Physiology.—In fig. 3 is given a diagram illustrating the structure of a cephalopod. Though schematic, this diagram gives a very fair idea of the organization of such forms as the common cuttlefish, squid and octopus. The view has been widely accepted that in the Cephalopoda the surface of the foot has become very much shortened as compared with that of other molluscs, the length of the body being reduced, while its height is increased. This modification of what we may assume to be the original plan of molluscan organization is held to have been brought about by the foot shifting forwards until it became involved in the head, its edges growing round and encircling the mouth. It will be seen in the section on Development that this process is actually indicated in the embryo, so that on this, as well as other grounds, we may regard the current view as to how the cephalopod organization was attained as substantially accurate. As to which surface of a cephalopod should be called anterior and which posterior we are on sound morphological ground if we regard the head and foot as ventral and the mantle-cavity as posterior. Nevertheless in many cephalopods, which move about by swimming, the long axis of the body becomes horizontal, like that of a fish, and the anterior surface might be more appropriately termed "upper" or "dorsal" and the posterior surface "under" or "ventral."

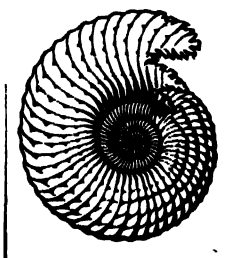


FROM LANKESTER, "TREATISE ON ZOOLOGY" (BLACK)
FIG. 3.—DIAGRAM ILLUSTRATING THE STRUCTURE OF A CEPHALOPOD

The viscera of our typical cephalopod are covered by a dome-shaped or elongated sheath of skin, the mantle, which is in close

contact with the body anteriorly, but posteriorly is free and encloses the mantle cavity, into which the gills project and the anus, kidneys and reproductive system open.

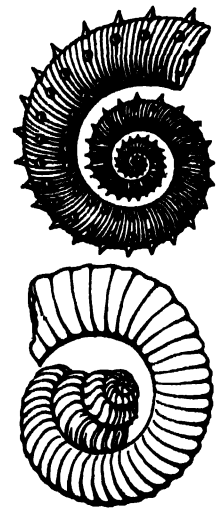
Below the visceral mass are the head and foot which together continue the main mass of the body. On the posterior side of this



(FISCHER)

FIG. 4.—CHIROTEUTHIS IMPERATOR (ABOUT ¼ NATURAL SIZE)

head-foot (cephalo-pedal mass) is a muscular tube, the funnel. The circlet of arms encircles the mouth.



The main divergences of structure have already been indicated in the section on classification; but, for the sake of rendering clear the importance of some of the details which follow, it is necessary to recall two important facts, first that *Nautilus* with its external coiled shell represents a more primitive and less specialized type than do the Dibranchia, a grade of organization seen in many anatomical features, and secondly that the Dibranchia have acquired a more active and vigorous mode of life that has led to certain marked departures in structure and function from the type represented by *Nautilus* and (we may assume) the ammonites. Lastly among the Dibranchia themselves certain important habitudinal divergences are established, and hand in hand with these we must note structural and physiological adaptations, *e.g.*, to a life permanently spent in the great depths of the sea, to a permanent floating life or to a more active and aggressive existence near the surface. The details of cephalopod anatomy and physiology may be studied in any good zoological textbook or in divers special papers and monographs. The following account attempts to eliminate detail and to present the main structural and physiological features of the class in relation to the mode of life of the animals concerned.

FROM "GUIDE TO FOSSIL INVERTEBRATES" (BRITISH MUSEUM)

FIG. 5.—A TRIASSIC AMMONITE, TRACHYCERAS AON (ABOUT ¾ NATURAL SIZE)

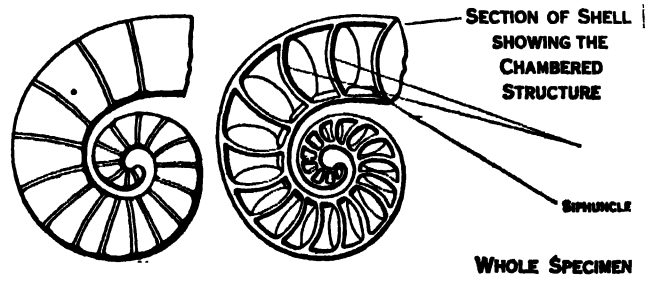
External Anatomy and General Organization.—The nautiloids and ammonites were in all probability mainly shallow-water animals living near the bottom. They relied for protection on a calcareous external shell and their speed of movement was probably inconsiderable. The modern *Nautilus* represents this mode of life pretty closely. The Dibranchia, are as we have seen, on the whole more active, and swimming or floating has become their characteristic mode of locomotion. Accordingly we notice the following features in their external organizations: (1) The mantle, which in the majority of molluscs and in the Tetrabranchia has a passive role and merely contains the viscera and secretes the shell, has become involved in the mechanism of locomotion. It has lost or almost entirely lost the rigid shell and has become highly muscular. Its expansion and contraction promote a locomotor water-current by drawing water into the mantle cavity and expelling it through the funnel. The rapid ejection of this jet of water enables the animal to execute rapid retrograde movements. As a means of sealing the mantle aperture while the locomotor jet is under compression, there is developed an "adhesive apparatus," a cartilaginous stud or ridge on each side of the edge of the mantle and a pair of corresponding sockets on the head into which the studs or ridges fit so that the mantle edge is locked to the head. (2) The funnel in *Nautilus* is represented by two muscular folds which meet in the middle line. In the Dibranchia these folds are completely fused up and form a complete tube. (3) Additional locomotor appendages in the shape of fins are developed from the sides of the mantle. These may become very large and no doubt assist in balancing the animal. (4) In accordance with their active, mainly reptorial mode of life, the circumoral appendages, which are many and feebly developed in *Nautilus*, are fewer in number in the Dibranchia, but more muscular and provided with suckers which in the Decapoda are furnished with horny, often toothed rims. In certain forms the teeth of the suckers are modified as large and formidable hooks. Two of the arms are specially modified in the Decapoda for the capture of prey

TEBRATES" (BRITISH MUSEUM)

FIG. 6.—UNCOILED CRETACEOUS AMMONITES (ABOUT ¾ NATURAL SIZE)

Upper, *Crioceras emericianum*. Lower, *Heteroceras emericianum*

Internal Anatomy.—(1) *Internal supporting structures.* All the Cephalopoda have an internal cartilaginous covering of the main ganglia of the nervous system. In the Dibranchia this is more complete than it is in *Nautilus*. It encircles the ganglia and constitutes a kind of skull. Besides this structure the greater



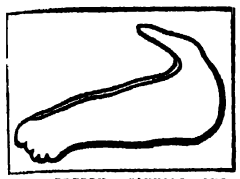


FIG. 7.—SPIRULA PERONII (ABOUT ½ NATURAL SIZE)

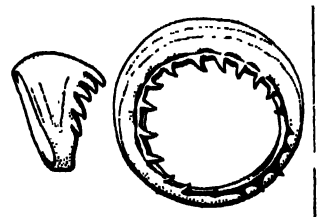
mobility of the Dibranchia is secured by other skeletal supports of the muscles which are found at the base of the fins, in the "neck," gills and arms of various forms. (2) *Viscera.* The alimentary system of the Cephalopoda consists of a muscular *buccal* mass furnished with a pair of jaws (mandibles) and a rasping tongue (radula), oesophagus, salivary glands, stomach, coecum, liver and intestine. Efficient mastication is secured by the

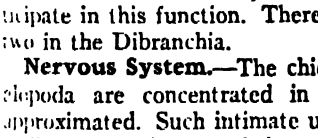


powerful mandibles and sharp-pointed teeth of the radula. In the Octopoda the oesophagus is expanded to form a crop and in the Cirrata, possibly in relation to the special diet of these mainly deep-sea animals, which seem to feed on bottom débris, the radula is frequently degenerate or absent and there is a "second stomach," a capacious dilatation of the intestine. In the Dibranchia the pancreatic element of the liver is partly separated from the latter. Nearly all the members of this subclass have a diverticulum of the intestine situated near the anus in which is secreted a dark fluid ("sepia" or "ink"). This can be forcibly discharged, and the dark cloud thus formed in the water serves as a means of escape from enemies. (*See* section *Distribution and Natural History.*) This so-called ink-sac is absent in *Nautilus* and in certain deep-sea Octopoda.

FROM ROBSON, "ANNALS AND MAGAZINE OF NATURAL HISTORY" (TAYLOR & FRANCIS)

FIG. 8.—ARM-HOOK OF MESONYCHOTEUTHIS HAMILTONI (HIGHLY MAGNIFIED)

Circulatory and Respiratory System.—These systems are very highly developed in the Cephalopoda. Unlike the rest of the Mollusca the blood is conveyed to and from the tissues in vessels instead of mainly through a system of diffuse cavities (*lacunae*), though the vascular system of *Nautilus* is partly lacunar. The process of circulation and oxygenation is more concentrated in the Dibranchia, which have only two cardiac auricles and two gills instead of four auricles and four gills as in *Nautilus*. The mechanism of respiration is likewise more efficient in the Dibranchia, the rhythmical contractions and expansion of the mantle musculature procuring a very effective circulation of water over the gills. The latter are feather-like in general plan, *i.e.* they consist of a central axis with side-branches disposed down each side of it. There are as many as 50 filaments a side in some Dibranchia; but in the Octopoda they are less numerous, and in abyssal forms (*e.g.*, the Cirroteuthidae) they are very much reduced in number and length.



FROM JATTA, "CEFALOPODI" IN "FAUNA UND FLORA DES GOLFES VON NEAPEL" (STAZIONE ZOOLOGICA DI NAPOLI)

FIG. 9.—TWO VIEWS OF THE HORNY RINGS OF SUCKERS OF TODARODES SAGITTATUS

Note the sharp teeth on the rims

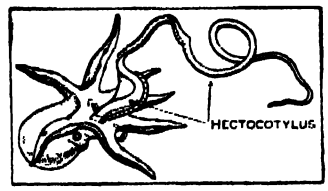
Renal Organs.—The excretion of nitrogenous waste is carried out exclusively by the kidneys; the liver, which in certain other molluscs has an excretory as well as digestive role, does not participate in this function. There are four kidneys in *Nautilus* and two in the Dibranchia.

Nervous System.—The chief ganglionic centres of the Cephalopoda are concentrated in the head and are very closely approximated. Such intimate union is not usually found in other molluscs, but is nevertheless seen in certain Gastropoda. This condensation of the central nervous system is seen in *Nautilus* and is carried still further in certain Dibranchia. Features indicative of functional specialization are found in the latter, *e.g.*, in some of the Teuthoidea the cerebral centres are subdivided and the pedal ganglia are likewise divided into brachial and epipodial elements which innervate the arms and funnel respectively. The sense-organs of the Cephalopoda are eyes, rhinophores (olfactory organs), statocysts (organs for the nervous regulation of balance) and tactile structures. The eyes of *Nautilus* are of a more primitive construction than those of the Dibranchia in that they have no retractive lens and the optic cavity is open to the exterior. In the Dibranchia the eyes are very complex and approach those of the Vertebrata in efficiency.

FROM LANKESTER, "TREATISE ON ZOOLOGY" (BLACK)

FIG. 10.—ROW OF TEETH IN RADULA OF AN OCTOPUS (HIGHLY MAGNIFIED)

Reproductive System.—The sexes are separate in the Cephalopoda. No instances of hermaphroditism or of sex-change such as are found in other molluscs have so far been reported in this class. Sexual dimorphism is of fairly regular occurrence; but it is usually expressed in slight differences of size and the proportion of various parts. In the pelagic Argonautidae (Octopoda) the male is very much smaller than the female, and in the cuttlefish (*Doratosepion confusa*) the males are distinguished by the possession of long tail-like prolongations of the fins. In nearly all cephalopods the males are in addition distinguished by the modification of one or more of the appendages as an organ of copulation. The male reproductive system is on the whole a little more complex than the female, chiefly in relation to the method of copulation. The spermatozoa are transferred by the male to the female in long tubes (spermatophores) which are formed in a special sac (Needham's organ) on the course of the male *vas deferens*. These tubes are deposited either in the neighbourhood of the mouth of the female (*Nautilus; Sepia, Loligo* and other Teuthoidea) or in the mantle-cavity (Octopoda; certain Teuthoidea) by means of the copulatory organ (hectocotylus [Dibranchia]: spadix [*Nautilus*]). The latter is a simple spoon-like modification of one of the arms in the Octopoda. In the Decapoda a great diversity of modifications is found which may involve more than one arm. Similarly in *Nautilus* an accessory copulatory organ (*antispadix*) is found. It has recently been suggested that some of the peculiar modifications found in the Decapoda enable the copulatory arm or arms to be used as an organ of stimulation.



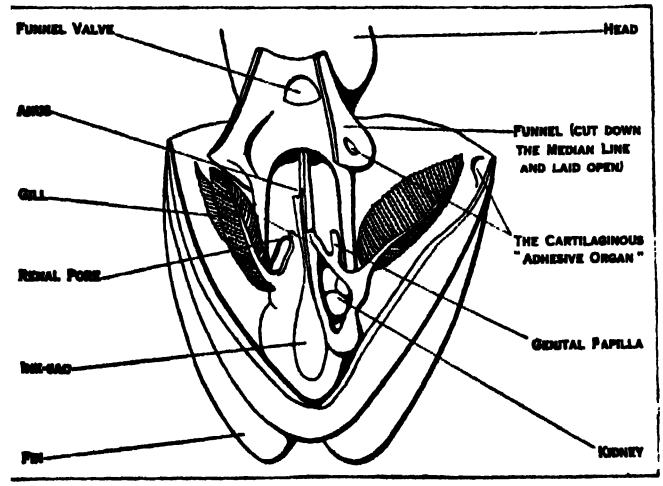


FIG. 11.—MALE OF ARGONAUTA ARGO SHOWING HECTOCOTYLUS; (ABOUT NATURAL SIZE)

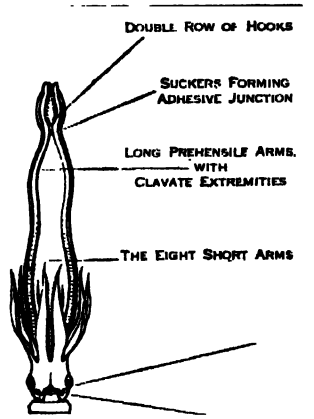
Colour Change and Luminescence.—Besides the permanent colour of the skin, the Dibranchia possess a cutaneous system of contractile cells (chromatophores) containing pigment which can be expanded or contracted so as to exhibit or conceal the pigment either of all the cells simultaneously or only of those containing a certain pigment. The circumstances in which these changes are brought about are discussed in the section on *Distribution and Natural History.*

In certain Decapoda, principally those which live at great depths, special light-organs are developed in various regions of the mantle, arms and head. These organs are not found in *Nautilus* and the Octopoda (except in *Melanoteuthis lucens*).

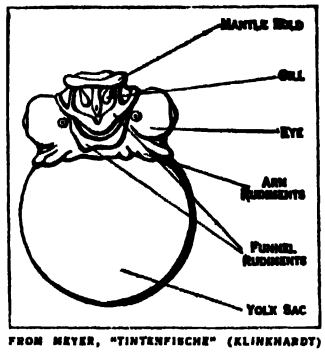


FROM LANKESTER, "TREATISE ON ZOOLOGY" (BLACK)

FIG. 12.—THE MANTLE CAVITY OF A CUTTLEFISH (SEPIA) OPENED IN ORDER TO DISPLAY ITS CONTENTS

They are only sparsely found in the littoral *Sepiidae* and *Loliginidae;* but a special type of light-organ said to produce the peculiar phenomenon of "bacterial light" has been described in certain species of *Sepiola* and *Loligo* (Meyer: Pierantoni. Robson).

Development.—The development of *Nautilus* is unfortunately not yet known, so that if any clues to the phylogeny of the cephalopods may be obtainable from the embryology of their



most primitive living representative, they are still withheld from us. The eggs of all cephalopods are provided with a remarkable amount of yolk so that, unlike that of the rest of the Mollusca, the segmentation is incomplete and restricted to one end of the egg. The embryo is likewise localized at that end and the ectoderm appears stretched out over one extremity of a large mass of yolk. Later on, a sheet of cells is developed below the ectoderm, commencing from that edge of the ectoderm at which the anus is subsequently developed; and after this, cells migrating inwards from the ectoderm give rise to the mesendoderm. The development of the various organs need not occupy us; but it is necessary to point out that the mouth in the early stage of development is not surrounded by the arm-rudiments. The latter arise as outgrowths of the lateral and posterior edges of the primordial embryonic area. These outgrowths pass forwards during later development until they reach and encircle the mouth. The funnel arises as a paired outgrowth of the same area, a condition which is retained in the adult *Nautilus,* while in the Dibranchia the two portions fuse together in the median line. The development of the Cephalopoda varies somewhat after the germ layers have been developed, according as to whether there is a yolk-sac or not. The embryo of *Sepia, Loligo* and *Octopus* is provided with a yolk-sac which may become partly internal; while in certain Decapoda presumed to be archaic there is less yolk and the yolk-sac is practically absent ("Oigopsid embryo" of Grenacher). Nevertheless, although we may regard the latter mode of development as less specialized than that of the heavily yolked egg, *e.g.*, of *Sepia,* there is no certain indication in the development of any known cephalopod of those larval phases that characterize the development of other Mollusca. The embryological history of the members of the Cephalopoda reveals as much specialization and differentiation from the more primitive molluscan type of development as does the structure of the adult.

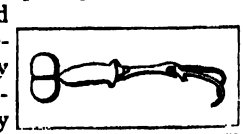
FROM TODD, "ENCY." (LONGMANS, GREEN, & CO.)

FIG. 13.—ARMS AND TENTACLES OF A LARGE SQUID, ONYCHOTEUTHIS

Phylogeny and Evolution.—The structure of the soft parts of fossil cephalopods is only very scantily known, so that our knowledge of the evolution of the class since its first appearance in Cambrian times is largely based on the shell. It thus follows that our main division of the class into Tetrabranchia and Dibranchia, based as it is on the structure of the gills and other primitive traits seen in the visceral anatomy of *Nautilus,* has little relation to our knowledge of the primitive nautiloids and ammonoids. Similarly our knowledge of the evolution of the Octopoda, in which the shell is vestigial and non-calcified, is rather compromised by the absence of verifiable fossil remains.

FROM MEYER, "TINTENFISCHE" (KLINKHARDT)

FIG. 14.—EMBRYO OF LOLIGO



In order to understand the evolutionary history of the Cephalopoda as revealed by the geological record, it is necessary to allude to the shell of *Nautilus,* which, by reason of its general organization, is regarded as the most primitive living cephalopod. This shell is coiled and subdivided into a number of closed chambers, the last of which is occupied by the animal. Throughout the system of chambers runs a median tube, the siphuncle. The earliest forms which we can recognize as cephalopods are found in Cambrian rocks. In *Orthoceras* (fig. 17) we see the unmistakable chambered shell and median siphuncle of the nautiloid. The shell is, however, straight, not coiled. At a later stage we find the shell becoming coiled like that of a true *Nautilus.* This is well seen in the Silurian *Ophidioceras.* In Triassic rocks are found remains closely resembling our modern *Nautilus;* but the latter did not actually appear until the early Tertiary.

This short sketch gives us a clue to the first stage in the evolution of the Cephalopoda. If we accept the view that the Mollusca are a homogeneous group, it is reasonable to suppose that the primitive Mollusca from which the Cephalopoda sprang were provided with a simple cap-like shell not unlike that of a limpet. What circumstances of adaptation or internal momentum dictated the lines on which cephalopod evolution should proceed are not known; but the first result was an elongation of the shell achieved by the deposition of lime salts around the edge of the primitive cap-like shell as the animal progressively shifted its position away from the apex. At each successive growth-period the back of the visceral mass secreted a partition (septum), thus forming the successive compartments of the nautiloid shell. The elongate shell thus produced, which we see in *Orthoceras,* no doubt became unmanageable and liable to injury. As in the case of the Gastropoda, it became coiled, which had the mechanical advantage of saving the shell from accident and making it more manageable. The second order of tetrabranchs, the ammonites, which are only known from fossil forms, was a very large group and the plentiful remains of their shells at certain horizons has provided material for special studies of evolutionary phenomena at once fascinating and baffling. The ammonites are ranked as Tetrabranchia on conchological grounds; but we do not know in fact whether they possessed the anatomical structure of the nautiloids. They differed essentially from the true nautiloids in having a marginal siphon and a persistent embryonic whorl at the apex of the shell (protoconch). It is customary to derive them from Devonian forms with straight shells, such as *Bactrites,* though in fact *Bactrites* itself has certain nautiloid traits. Coiled ammonites appear in the upper Devonian (*Goniatites*), and thereafter follow a great variety of forms. They are distinguished by tendencies towards uncoiling and great complexity of the sutures (line of junction between the septa and the main shell-wall) which illustrate remarkable phenomena of growth (mostly modifications of the principle of Recapitulation). Some lineages (or evolutionary strains) illustrate retrogressive evolution, the later members of such series reacquiring traits seen in earlier stages of the series. These retrogressive stages are especially noticeable in the Cretaceous period, at the end of which the ammonites became extinct. It is not yet safe to say that this group as a whole ran a straight course through increasing complexity to a climax from which they passed to senescence and ultimate decay. It is tempting to read such a plain evolutionary theme into their story; but it seems more likely that as Swynnerton suggests, they were cut off when still a flourishing group by a great secular "revolution" of climate and earth-change, rather than by the exhaustion of their own evolutionary momentum. The history of the dibranchiate Cephalopoda is dominated by one main evolutionary theme. Our modern squids, cuttlefish and octopods are distinguished from the nautiloid forms by the possession of an internal and partly degenerate shell. In one form alone (*Spirula*) the shell is still partly external. The position and state of the shell in the

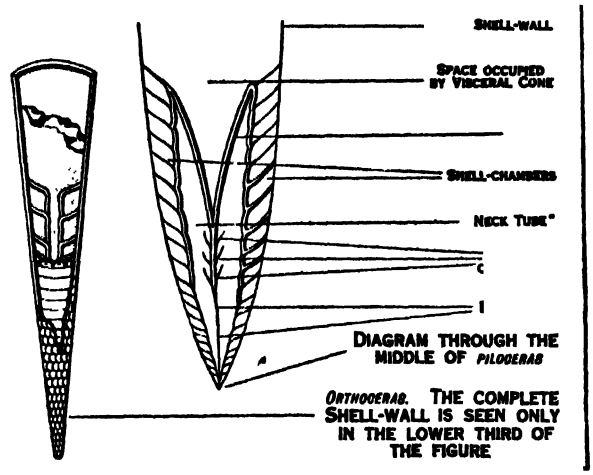
CUTTLEFISH, OCTOPUSES AND SQUIDS OF THE MEDITERRANEAN

1. Squid (*Todarodes sagittatus*)
2. Common squid (*Loligo vulgaris*)
3. Octopus (*Rossia macrosoma*)
4. Squid (*Loligo marmorae*) discharging the ink which squids eject as a screen against their enemies
5. Paper nautilus (*Argonauta argo*)
6. Octopus (*Scaeurgus tetracirrus*)
7. Octopus (*Ocythoe tuberculata*)
8. Common cuttlefish (*Sepia officinalis*)
9. *Sepiola aurantiaca*
10. Eggs of cuttlefish (*Sepia officinalis*)
11. Common octopus (*Octopus vulgaris*)

Dibranchia is due to the progressive overgrowth of the shell by the mantle and the formation around the shell of a secondary sheath, the various parts of which eventually become larger than the shell itself. The loss of the true shell probably went hand in hand with the gradual acquisition of an active swimming habit, in which the protection of a rigid outer covering was replaced by greater mobility entailing the development of



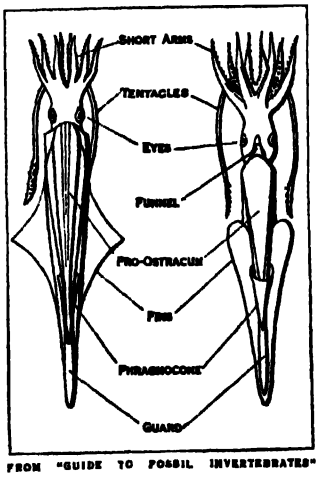


FIG 17 DIAGRAM OF SECTIONS THROUGH THE SHELL OF PALAEOZOIC NAUTILOIDEA, SHOWING THE CHAMBERED STRUCTURE

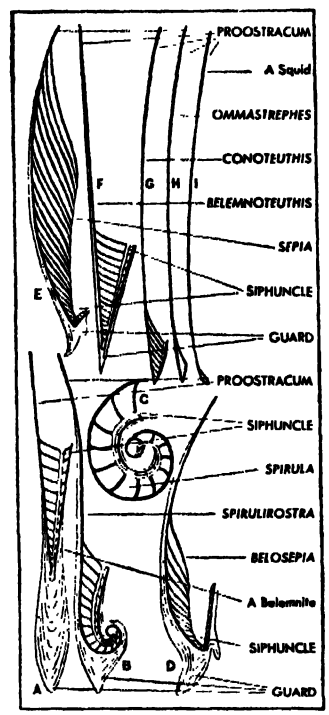

stronger pallial muscles. At the same time the acquisition of a fresh orientation probably entailed a readjustment of the centre of gravity of the animal, the heavy, more or less terminal shell being incompatible with rapid movement in a horizontal position. Of forms which connect the Dibranchia with the Tetrabranchia we have no direct evidence. According to Naef we may distinguish certain orthoceratid nautiloids which show an approach to the oldest Dibranchia; but it is not until Triassic times that we meet in *Aulacoceras* unmistakable evidence of the modification of the shell. This tendency is seen at its best in the Belemnites. It consists primarily in the enclosure of the apex of the shell in an external calcified sheath, the guard, and the development of an accessory plate, the pro-ostracum, at the anterior end of the shell. The forms which exhibit these modifications were undoubtedly dibranchiates, as they possessed the characteristic ink-sac and hooks on their suckers. The belemnites gave rise to several lines of descent. In one of these the guard is reduced and the original shell (phragmocone) is coiled (*Spirulirostra*). Further reduction of the guard and more extensive coiling of the phragmocone produced the shell of the modern *Spirula*. In another line the guard is similarly reduced, and the extension of the phragmoconal septa as closely set and numerous layers up the surface of the pro-ostracum led through the *Belosepia* to the modern cuttlefish. The modern Teuthoidea (*Loliginidae* and "Oigopsida") are distinguished by the loss of phragmocone and guard and the persistence of the pro-ostracum as a horny "pen." These forms appear in the Jurassic and are probably developed from belemnite-like ancestors. Of living Teuthoidea *Ommastrephes* preserves a trace of the phragmocone.

FIG. 18.—RESTORATION OF THE ANIMAL AND SHELL OF A BELEMNITE
Left, dorsal view; right, ventral view

Owing to the great reduction of the shell in living Octopoda, in which it persists as fine cartilaginous "stylets" or as somewhat better-developed fin-supports (Cirrata), the stylets, or fin-supports, are usually regarded as vestiges of the shell; but it is possible that this interpretation is wrong. We have no knowledge of the ancestry of this group. The structure of *Palaeoctopus newboldi* from the Cretaceous of Syria affords no clue to the early stages of octopod evolution. This form combines cirromorph and octopod characters; but in general it appears to be more octopus-like. Of the modern Octopoda it is likely that the Cirrata, in spite of much specialization in relation to the abyssal habit, are an older group than the true octopods. As far as the rudiment of the shell is concerned such forms as *Cirroteuthis mülleri* and *Vampyroteuthis* are more primitive than *Octopus*, *Eledone* and the *Argonautidae*.

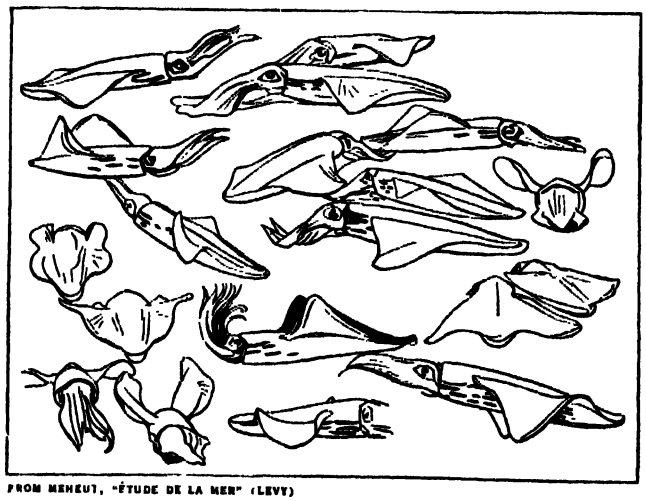
FIG. 19.—THE BELEMNITE AND ITS DESCENDANTS. SECTIONS THROUGH THE MIDDLE OF THE SHELL

Distribution and Natural History.—The Cephalopoda are exclusively marine animals. No authentic records are available of their occupation of fresh or brackish water. Although they are occasionally carried into estuaries, they do not tolerate water of reduced salinity. In this respect they are comparable with the Amphineura and Scaphopoda among other Mollusca and with the Echinoderma and Brachiopoda. It is interesting, but rather fruitless to speculate as to why so highly organized and dominant a group has never, as far as we know, accommodated itself to fresh water. The fact that there are many littoral species further emphasizes this exclusiveness. One record is known to the author of an octopod being found living at the mouth of a fresh water stream (Hoyle, 1907), and it is interesting to note that certain species have penetrated into those areas of the Suez canal which have a *higher* salinity than that of normal sea water. No differences have so far been recorded in the numerical frequency of the cephalopods of those parts of the ocean which have a relatively low salinity (*e.g.*, under 34 per mille, as in Arctic and Antarctic waters), and those with an average or high salinity (35 per mille and upwards). In areas of extremely low salinity, such as the Baltic sea, cephalopods are very sparsely represented.

Concerning the horizontal (geographical) distribution of cephalopods, as far as it can be dissociated from the vertical distribution (*see* later), little need be said. Many genera and some species are, in the light of modern taxonomy, cosmopolitan in their distribution. Thus the small oigopsids *Cranchia scabra* and *Pyrgopsis pacificus* are found in the Atlantic, Indian and Pacific oceans, though they do not pass into high latitudes. The common European *Octopus vulgaris* and *O. macropus* have, on unimpeachable authority, been recorded from the Far East. On the whole the distribution of the species and some of the genera is very much the same as in other great groups of marine animals, *i.e.*, it is in general determined by the great oceanic "divides." Thus the Canaries current cuts off a north-east Atlantic fauna from an equatorial and south Atlantic one at about latitude 18°N., and the great "divide" off Cape Agulhas (South Africa) separates Atlantic and Indo-Pacific faunas. Nevertheless, these barriers (due to marked changes in salinity and temperature) seem to be by no means rigid in their effects. Several Mediterranean species are found in the south Atlantic and certain species are common to the Atlantic and Indo-Pacific regions; so that the species can only be grouped into faunas in a very broad fashion. Other qualifications have also to be made. In the first place it is very likely that many species which occur at the surface, *e.g.*, in the cold



Benguela current of the south-east Atlantic may be found in deeper water in the Indian ocean, so that the Agulhas "divide" may be only effective at the surface and have a limiting effect only on those Cephalopoda which cannot descend to great depths. Secondly, the identification of species from contrasted areas should depend on a very exact taxonomy, and this is not always easy in practice, as the condition and number of specimens collected is not always satisfactory. It will be convenient to consider vertical distribution at the same time as the general mode of life of these animals. *Nautilus* seems to keep near the bottom in the neighbourhood of islands and reefs and has been obtained at a depth of 300 fathoms. It comes into shallow water quite frequently; but Dr. A. Willey believes it breeds in very deep water. The larger Decapoda spend their life swimming at various depths. Some are strictly littoral such as *Sepia* and *Loligo*. Most of the Teuthoidea are pelagic, *i.e.*, they live in the open sea far from land, and some of them have a very considerable vertical distribution. *Chiroteuthis lacertosa* has been taken at a depth of 2,949 fathoms.

FIG. 20.—CIRROTEUTHIS UMBELLATA, AN ABYSSAL OCTOPOD

In the adult stage the small and fragile Cranchias (Oigopsida consuta) are to be reckoned as planktonic organisms, *i.e.*, floating more or less at the mercy of currents rather than swimming with or against the latter. The Octopoda mainly dwell on or near the bottom either crawling on the latter or swimming a short distance off it. Some of them, however, *e.g.*, *Eledonella* and *Cirroteuthis*, are not confined to the bottom and are found in mid-water at very considerable depths. Although the large family of the Octopodidae mainly inhabits shallow water, the Octopoda as a whole contain a very large nucleus of deep water forms (one species of

FROM MENEUT, "ÉTUDE DE LA MER" (LEVY)

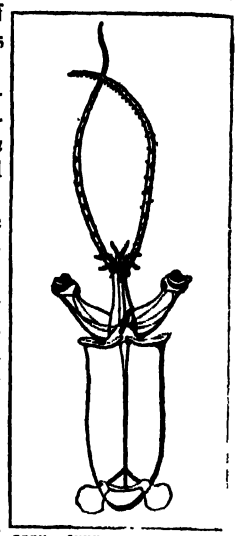

FIG. 21.—SQUIDS OF VARIOUS SPECIES SWIMMING

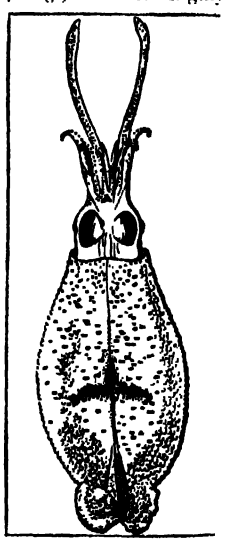
Eledonella has been taken in 2,900 fathoms), which display well marked adaptations to life in abyssal conditions.

Alcide d'Orbigny in his account of the Mollusca of South America, asserted that the Cephalopoda are in general "sociable," *i.e.*, gregarious, and this statement is certainly true of *Nautilus* which were always found together in droves by the native divers employed by Dr. A. Willey, who observed its habits in New Guinea, etc. Nevertheless, Jatta, who made a special study of the Mediterranean forms, was of the opinion that only certain pelagic forms are thus gregarious (*e.g.*, *Todarodes*, *Ocythöe*). We should avoid concluding that the coincidence of a large number of individuals necessarily implies either a sociable instinct or a desire for the protection afforded by a community, as it may be due to the accidental coincidence of large numbers of individuals ("population maximum") in somewhat restricted breeding or feeding grounds. Nevertheless, Verrill has adduced evidence that the shoaling of young *Loligo pealei* off the coast of New England is not thus accidental.



The breeding season has a marked effect on the distribution of certain Cephalopoda. The common cuttlefish (*Sepia officinalis*) comes into shallow coastal water in the spring and summer to breed, and migrations of a similar nature have been observed in other forms (*Loligo*, *Alloteuthis*).

Very little is known concerning the mating habits of the Cephalopoda. It has been assumed that in certain forms with special light organs, *e.g.*, *Sepiola*, *Loligo*, their organs serve as a means of sexual display. Nevertheless, it is not certainly known that such forms may not mate at depths, which render it likely that such organs function rather as a means of advertising the individual to its prospective partner than as an incitement to coitus. The actual process of coitus has been studied by several naturalists (Racovitza, Drew, Levy, etc.); but, while we know the general lines on which it takes place, the details and particularly those relating to the use of the hectocotylus are not very well known (see *Reproductive System*). Nor again are we informed as to the bionomic significance of some of the more remarkable cases of sexual dimorphism among these animals, *e.g.*, of the highly elongate and fringed arms of *Sepia burnupi* and *lorigera* (Massy, Wülker) and the still more remarkable dimorphism in *Doratoscopion confusa* (Massy and Robson, Robson and Carleton).

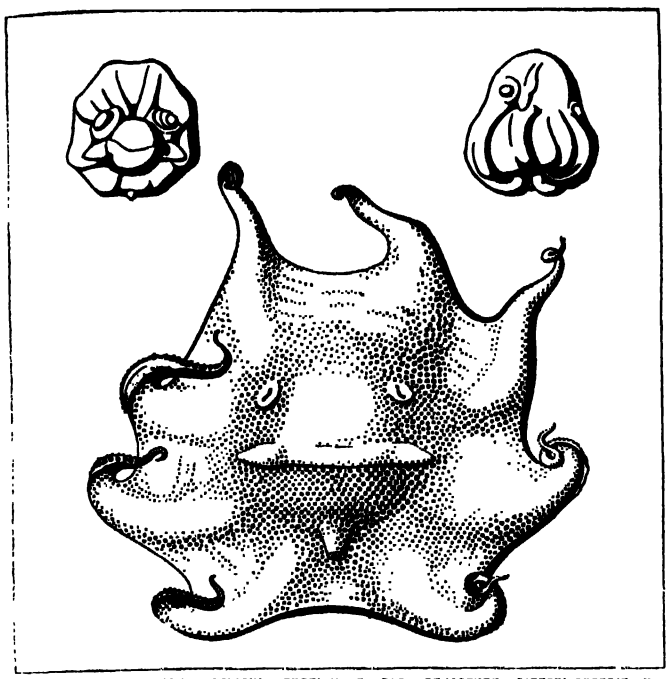
FIG. 22.—BATHOTHAUMA LYROMMA



FROM "WISSENSCHAFTLICHE ERGEBNISSE DER DEUTSCHEN TIEFSEE-EXPEDITION" (FISCHER)

FIG. 23.—CRANCHIA SCABRA

The eggs of most of the Cephalopoda, of which we know the reproductive habits, are laid inshore, and are usually fastened down singly or in clusters on bottom débris such as fragments of coral, stems of plants, etc. Less is known concerning the egg-laying of pelagic species, except in special instances such as that of *Argonauta*, in which a brood chamber is developed in the shape of a shell (not homologous with the true shell) which is secreted by the dorsal arms of the female. Brooding over the eggs seems to take place on the part of the female in certain forms (*e.g.*, *Octopus vulgaris*). Little is known concerning the relations between the sexes apart from those immediately concerned with reproduction. Grimpe, however, records that in captivity *Sepia officinalis* is strictly monogamous though capable of reproduction.

The majority of living Cephalopoda are carnivorous and live principally on Crustacea. Small fishes and other molluscs, however, often form part of their diet and there is some evidence that in nature certain species are cannibals. In the Channel Isles *Octopus vulgaris* partly subsists on the ormer (*Haliotis*) and has been made responsible (though on insufficient evidence) for a marked decrease in the numbers of that mollusc. The Cirrata whose reduced musculature and radula indicate a loss of activity and of masticatory power probably feed on bottom-débris or minute plankton. The latter in the shape of copepods, pteropods, etc., are probably the food of the smaller pelagic Decapoda. The Cephalopoda are in their turn preyed upon by whales, porpoises,

FIG. 24.—TWO HIGHLY MODIFIED OCTOPODS
figures, *Opisthoteuthis medusoides;* lower, *Opisthoteuthis*

dolphins, seals and sea birds. The stomachs of whales are often found to contain fragments of Cephalopoda (mandibles and sucker rings), and it is held that the waxlike substance known as ambergris, which is used in perfumery and is found floating at sea or drifted ashore, is composed largely of cephalopod tissue voided by whales. It is not to be doubted that large squids maintain a desperate struggle with any whale that may attack them, as specimens of the latter are sometimes taken with the marks of sucker rings imprinted in their skin.

The colour changes produced in the skin of most cephalopods by the contraction and expansion of the chromatophores have been variously interpreted as affording protective or obliterative coloration or as an expression of certain emotions. It is likely that both these effects are secured by this means. The common octopus has been observed to assume a very close mimetic resemblance to the colour of its background. On the other hand observations have been made on colour changes in *Sepiola atlantica* which seemed to be the reverse of protective, as judged by the human eye. The chief means of avoiding capture is, however, provided by the "ink" which is expelled from the ink sac when the animal is attacked. It was originally thought that the ink formed a kind of "smoke screen" behind or in which the animal was hidden from its enemy. Later observations, however, tended to suggest that the jet of ink, when shot out, remains as a definitely shaped object in the water and serves as a "dummy" to engage the attention of the enemy, while the cephalopod, changing its colour so that it is almost transparent, darts off in another direction. Whether this explanation is applicable to all cases is uncertain; and in any case it is uncertain why, if many cephalopods can assume something approaching protective transparency, it should be necessary to add to the means of concealment. The matter is plainly in need of further investigation. The Cephalopoda as a whole are not distinguished by individual eccentricities of behaviour. It is worth while, however, to mention three interesting cases: (1) many pelagic squids and cuttlefishes keep very near the surface when swimming, and one of them, "the flying squid" *Ommastrephes bartrami,* often shoots out of the water in rough weather and has been several times carried by its leaps on to the decks of ships; (2) the male of the pelagic octopod *Argonauta* is often found inhabiting the discarded case of the Tunicate *Salpa,* a habit in which it resembles the Crustacean *Phronima;* (3) Syun'iti Sasaki described a remarkable habit and structural modification in the small cuttlefish *Idiosepius paradoxus.* The latter, which is found in Japanese waters, is often found adhering to seaweeds by means of a rudimentary sucker developed in the dorsal region of the mantle. No instances of parasitism and only one doubtful case of commensalism were recorded among these animals.

Economic Uses.—The Cephalopoda are of considerable value to man, principally as a direct source of food. They also constitute a large part of the diet of certain animals, such as whales and seals, which are of economic importance and in certain parts of the world they are regularly caught on a large scale as bait for certain valuable food fishes. Squids, cuttlefishes and octopods are eaten by man in many parts of the world. Information concerning the people who regularly eat these animals is by no means complete as yet. The "Anglo-Saxon" people (possibly the "Nordics" generally) do not as a rule eat them, even when a regular supply is available. They are largely consumed by south European (Mediterranean) peoples and in India, Indochina, Malaya, China, Japan and the Pacific islands. Concerning the littoral natives of Africa and central South America no certain information is available. In the Mediterranean region cephalopods have been eaten since early times. They are either fried or boiled for the table; but in the east, *e.g.,* Indochina and south India, they are also sun-dried for human consumption. In Japan the squid fishery attains a very great importance and in one year more than 77,161 short tons of squid were landed (Imperial Japanese government statistics). *Ommastrephes sloanei* is the chief form taken in these fisheries. The bait fisheries of south India are a very important local activity and in North America the cod fishermen rely largely on various squids for baiting their lines. The only other important material obtained from cephalopods is "cuttlebone" (the internal shell of the *Sepiidae*). The uses of this article are described in the article CUTTLEFISH. Among primitive peoples and in ancient times in Europe various parts of cephalopods have been used in magical operations and in medicine. Cuttlebone has been used in the treatment of leprosy and for various disorders of the heart.

Historical.—The study of the Cephalopoda was initiated by Aristotle who devoted much attention to the group. The modern investigation of their morphology may be dated from Cuvier, who gave them the name by which they are now known. H. de Blainville (1777–1850) and Alcide d'Orbigny (1802-57) laid the foundation of the systematic study of the group, the great monograph *Mémoire sur les Céphalopodes Acétabulifères* of D'Orbigny being a landmark in systematic zoology. This work includes descriptions of fossil forms as well as of living species. R. Owen contributed substantially to the knowledge of the morphology of the class, particularly by his *Memoir on the Pearly Nautilus* (1832). A. Kölliker may be said to have founded the embryological study of cephalopods (1843) and Alpheus Hyatt (1868)

led the way in early palaeontological studies of these animals. The rarer pelagic and deep sea forms were only obtained slowly and, although the Cirrata were known as early as 1836 (Eschricht), it was not until toward the end of the last century that the "Challenger" expedition and the researches of W. Hoyle and A. E. Verrill obtained the first substantial contribution to our knowledge of these forms. Since then, C. Chun, I. Steenstrup, A. Appelöf, G. Pfeffer, L. Joubin, A. Naef, S. S. Berry, G. Grimpe, M. Sasaki and A. Massy have contributed to our knowledge of the living forms, while L. Branco, J. Foord and G. C. Crick, S. Buckman and R. Abel have organized the study of fossil forms. Particular mention must be made of the work of Naef, who subjected the living and fossil forms to a synthetic treatment. Apart from our lack of information concerning the development of *Nautilus* there still remains much work to be done, particularly on the habits and oecological relationships of these animals, and it is to be doubted whether we are yet in possession of a sound systematic arrangement of the Decapoda.

CEPHEUS, in Greek mythology, the father of Andromeda (*q.v.*); in astronomy, a constellation of the northern hemisphere. The star δ Cephei is the type star of a class of variables called Cepheids (*see* STAR). It was discovered by Goodricke in 1785. The period is 5·37 days and the range of magnitude is from 3·6 to 4·2. The star β Cephei is also a famous Cepheid variable; although its range of brightness is only 0·05 mag. its variability was detected by Professor Paul Guthnick of Berlin University by photoelectric measurements.

CEPHISODOTUS, the name of a near relative, and of the son of, Praxiteles, both sculptors like himself. The former must have flourished about 400 B.C. A noted work of his was Peace bearing the infant Wealth, of which a copy exists at Munich. Peace is a Madonna-like figure of a somewhat conservative type. He made certain statues for the city of Megalopolis, founded in 370 B.C. (*See* H. Stuart Jones, *Ancient Writers on Greek Sculpture* § 182–185 [1895].) Of the work of the younger Cephisodotus we have no remains; he flourished in the latter part of the 4th century B.C., and was noted for portraits of Menander, of the orator Lycurgus, and others. (*See* J. Overbeck, *Antike Schriftquellen*, p. 255.)

CERAM, an island of the Netherlands Indies, in the Molucca group. It lies 3° S. and between 127° 45′ and 131° E., and is due east of Buru, from which it is divided by the Manipa or Buru strait, in which are the islands of Manipa, Kelang and Boano. It is 216 mi. long, and has an area, with adjacent islands, of 6,621 sq.mi. Politically, it comes under the residency of Amboina, and for administrative purposes is divided into four districts—West Ceram, Amahai and Wahai (Middle Ceram) and East Ceram, with a *controleur* and three *gezaghebbers*. The island, which geologically is composed mostly of eruptive rocks and crystalline limestone in the middle and western portions, and of crystalline chalk in the east, is very mountainous, a fine range of mountains traversing it from east to west. The highest peak is that of Binaya (9,600 ft.), in the central part, and four others exceed 6,000 ft. In some places the mountains extend right to the coast; in others wide stretches of lowland are sometimes fringed with swamps by the seashore.

There are many rivers, running to the north mostly; they are partly navigable for small craft only during the rainy season and often dry up altogether during the period of drought. Comparatively little is known of the interior of the island, with the exception of the peninsula of Hoalmoal in the west, which is connected with the main island by a low, narrow isthmus. With Ceram are included Ceram Laut, a cluster of islands on a coral reef, about 20 mi. long, also Gisser and Kilwaru, the Goram (or Gorong) Islands (Suruaki, Goram and Manawoka), the Watubela group, and the Teor Isles, all of which lie southeast of Ceram.

The larger islands are of Tertiary (Miocene) formation, and the others of recent coral. None has hills of over 1,000 ft. and most are thickly wooded, while Suruaki has extensive swamps. Many of the Watubela islands have rugged hills covered with coconut palms, and some of the Teor group are entirely waterless, owing to the nature of their coral rock.

Ceram is covered with dense tropical forests, which provide excellent timber (ironwood is general) and yield a variety of forest products, including cajeput oil, damar and wild nutmeg, and in the swamps of the coast and valleys the sago palm thrives abundantly. Both the flora and the fauna of the island lack variety and characteristic specimens; of a forest in the centre A. R. Wallace wrote: "I have never been in a forest so utterly desert of animal life as this appeared to be." The cassowary is the outstanding feature of the fauna, which includes deer, cuscus, pig shrews, cockatoos, lories, hornbills and birds of paradise, and there are many species of fish in the rivers. The climate is hot and moist, the rainfall being a heavy one, and earthquakes occur. Ceram had in 1930 a population of 95,636, largely in coastal regions and composed mostly of immigrants from Java, Macassar, Ternate and other parts of the archipelago. The people are partly Christian and partly Mohammedan. The Christians live mainly in the west (the Mohammedans in the southeast) and dress and live in the style of the Christian Amboinese, to whom they are nearly related. Fishing and agriculture are the chief pursuits. Most of the tropical fruits of Malaya are grown, also rice, maize, sugar cane, tobacco and coconuts; sago flour is produced and cajeput oil distilled. Trade in these products is in the hands of Chinese, Arabs and Macassars, but there are also some coconut, spice and other plantations under European supervision and copra is the chief article of export. There is a small oil field near Buli Bay (east coast), producing 117,946 tons of crude oil in 1939. The people of the coasts are semi-civilized; not so those of the interior, who are of a mixed Malay-Papuan stock; the practice of head-hunting, however, is becoming a thing of the past. They are largely pagan in religion, wear little in the way of clothing, live in houses built on piles and use as weapons the bow and arrow, *parang* and lance. They are hunters and fishers, and collect forest products, keep pigs and dogs, have a patriarchal social system and a form of marriage sometimes endogamic, sometimes exogamic. Women have a good position among them and are well treated, and, especially among the mountain folk, morality is high. Weaving is known in some parts, and weapons and plaited goods are manufactured. China plates and dishes are considered objects of the highest value, and the people like

long ceremonial feasts. There is a secret society among the people of the west, the *Kakihan*, the main object seeming to be maintenance of old customs in the face of foreign influence, but it has also a strong religious significance, initiation being a form of death and resurrection ritual; and the people generally are divided into the two divisions of *Pata-siwa* (the Ternate party) and *Pata-lima* (the Tidore party). The Ceramese are a strong and muscular people, cheerful and honest, but inclined to be very excitable, and extremely independent. The natives of the middle and east are far more peaceful in their ways than those of the west, but civilization is making headway among all, as the result of increasing trade facilities and the provision of schools in many districts, maintained by the Dutch government, with Amboinese headmasters. Amahai, in the south (centre), has a good harbour. Other ports of call are Piru (west), Wahai (north), Tehoru (south) and Bula Bay (east); roads are nonexistent. There is an airfield at Bula Bay. Ceramese, a language without either script or literature (yet the people sing songs of former ages which have been handed down orally), is divided into thirty-five different dialects, and is nearly related to the indigenous language of Amboina. Malay is used commonly on the coasts. The people of the Ceram Laut Islands (pop. 6,000), Gisser and Kilwaru are Mohammedan. They are fishers, build boats, weave sarongs, manufacture knives and live in quite well-built wooden houses, in tidy villages, generally by the seashore. Gisser, with Kilwaru, is a trade centre for the region of southeastern Ceram and the islands and is a port of call for vessels of the Royal Packet Navigation Co.

The population of the Goram Islands, which are more fertile than those of Ceram Laut, is also about 6,000, and Mohammedan, the people being fishers and traders and the women good weavers. The Watubela islanders are Mohammedan also; they produce scarcely anything beyond copra, which they trade for the products they lack. Boano has a population of 1,300, Christian and Mohammedan, and an infertile soil, which drives its people to seek a livelihood on neighbouring islands, and Manipa has nearly 1,000 inhabitants, who grow a good deal of sago.

In the mid-17th century a fort established at Cambello extended Dutch influence, with help from Ternate, which claimed suzerainty. The power of Amboina later helped the Dutch to acquire the whole island in spite of trouble when they destroyed clove plantations in order to uphold Amboina's monopoly. Later still, there were expeditions against the natives of the interior, but after 1910 all was quiet. During World War II, Ceram was occupied by the Japanese in Feb. 1942.

BIBLIOGRAPHY.—A. R. Wallace, *The Malay Archipelago* (1890).

(E. E. L.; X.)

CERAMICS or **KERAMICS,** a general term for the history and art of making pottery. (*See* POTTERY AND PORCELAIN.)

CERARGYRITE, the name usually applied by mineralogists to naturally-occurring silver chloride, though sometimes taken to include the bromide and iodide as well, or mixtures of them. It crystallizes rarely in the cubic system, but usually forms horn-like masses, known to miners as horn-silver. It is very soft, being easily cut with a knife, and usually of a dirty grey or yellowish colour. It is an important ore of silver, occurring in considerable quantity in the oxidation zone of silver lodes in dry climates, such as Chile, Peru, and Broken Hill in New South Wales, where the surface waters are rich in chlorides, bromides and iodides.

(R. H. RA.)

CERATOSAURUS, an extinct carnivorous dinosaur whose remains are found in the Upper Jurassic of Colorado. Like its relatives Allosaurus (*q.v.*) and Tyrannosaurus (*see* DINOSAURIA), was bipedal in progression. The single species, *C. nasicornis,* reached a length of 20 ft. and, as its name implies, was distinguished by a small horn on the nose. (*See* REPTILES.)

CERBERUS, in Greek mythology, the dog who guarded the entrance to the lower world. According to Hesiod (*Theog.*, 311), he was a 50-headed monster, the offspring of Typhon and Echidna. He was variously represented with one, two or (usually) three heads, often with the tail of a snake or with snakes growing from his head or twined round his body. One of the tasks imposed upon Hercules was to fetch Cerberus from below to the upper world, a favourite subject of ancient vase paintings.

CERCIDIPHYLLUM, a genus of plants of the Trochodendraceae family. *C. japonicum,* the katsura tree, native to Japan, is a hardy, ornamental, shrubby tree of pyramidal habit, almost fastigiate when young, with handsome light green foliage, purplish when unfolding and turning bright yellow or partially scarlet in autumn. Commonly there are several trunks, usually 20–30 ft. in height, but sometimes attaining 100 ft.

C. japonicum var. *sinense,* from western China, usually consists of a single trunk which may exceed 100 ft. It is the largest of all broad-leaved trees known from China; the trunk is often free of branches for nearly 50 ft. above the ground and may attain a girth of 25 ft. or even more. (J. M. BL.)

CERDIC (d. 534), founder of the West Saxon kingdom, is described as an ealdorman who in 495 landed with his son Cynric in Hampshire, where he was attacked at once by the Britons, under Natanleod. Nothing more is heard of him until 508, when he defeated the Britons with great slaughter. Strengthened by fresh arrivals of Saxons, he gained another victory in 519 at Certicesford, the modern Charford, and in this year took the title of king. Turning westward, Cerdic appears to have been defeated by the Britons in 520 at Badbury or Mount Badon, in Dorset, and in 527 yet another fight with the Britons is recorded. His last work was the conquest of the Isle of Wight (530), probably in the interest of some Jutish allies.

See E. Guest, *Origines Celticae* (1883); Bede, *Historiae ecclesiasticae gentis Anglorum libri,* v, ed. C. Plummer (Oxford, 1896); Gildas, *De excidio Britanniae,* ed. Th. Mommsen (1898); Nennius, *Historia Brittonum,* ed., Th. Mommsen (1898); *Anglo-Saxon Chronicle,* edited by C. Plummer (Oxford, 1892–99).

CERDONIANS, a Gnostic sect, founded by Cerdo, a Syrian, who came to Rome about 137, but concerning whose history little is known. Most of what the Fathers narrate of Cerdo's tenets has probably been transferred to him from his famous pupil Marcion, like whom he is said to have rejected the Old Testament and the New, except part of Luke's Gospel and of Paul's Epistles. (*See* MARCION AND THE MARCIONITE CHURCHES; also GNOSTICISM.)

CEREALIS (CERIALIS), **PETILLIUS** (1st century A.D.), Roman general, a relative of the Emperor Vespasian. In A.D. 61 he was in Britain as legate of the ninth legion, which was overwhelmed by the Britons. In the civil war of 69 he supported Vespasian, and in 70, after holding the consulship, he put down the revolt of Civilis (*q.v.*). In 71, as governor of Britain, where he had as a subordinate the famous Agricola, he defeated the powerful Brigantes. Tacitus says that he was a bold soldier rather than a careful general.

See Tacitus, *Annals,* xiv, 32; *Histories,* iii, 59, 78; iv, 71, 75, 86; v, 21; *Agricola,* 8, 17. *See* also B. Henderson, *Civil War and Rebellion in the Roman Empire* (1908).

CEREALS. Cereals are those members of the grass family which have edible starchy seeds. Rice, wheat, rye, barley, oats, maize (known as corn in the Americas), sorghum and some of the millets are the common cereals. All are summer or winter annuals and are grown primarily for the seed which is used for human food or as feed for livestock.

Cereals have provided the basis on which the civilizations of the world have been developed. When ancient man discovered these plants which provided a source of food and learned how to grow them, roving bands were transformed into settled communities. The growing of these crops required much less of primitive man's time to provide the necessary food for himself and family and feed for his animals, thus leaving time to develop the arts and sciences which distinguish civilized man from the savage. Cereal grains now as in ancient times provide more food with a smaller expenditure of effort than any other crops. Because of their low moisture content they are easily stored and transported. Grain storehouses have been found in the excavated ruins of many ancient cities: wheat and barley in those in Mesopotamia, Egypt, Greece and Rome, and maize in the ruins and caves of the Mayas, Aztecs, Incas and other Indian peoples of the western hemisphere.

Wheat, rice and rye are grown primarily for human food, while maize, barley, oats and sorghum are grown mostly for livestock

feed although in some countries even these are important food crops. Because they can be easily shipped without loss or deterioration in quality and are grown in some countries in great excess of local needs, wheat and rice are shipped in large quantities into countries which do not produce enough starchy foods to meet their domestic needs. On the other hand a large part of the maize, barley, oats and sorghum, especially in the English-speaking nations, is fed to livestock on the farms where it is grown and is sent to markets in the form of meat, dairy and poultry products. During World War II a large amount of wheat and maize was used in the United States to produce alcohol for the manufacture of munitions and synthetic rubber.

Wheat is the aristocrat of cereals and is grown on a larger world acreage than any other crop. It is adapted to a wider range of climatic conditions than any other crop with the possible exception of barley. However the important wheat-growing regions of the world are confined to the temperate zones where the annual rainfall is between about 13 and 35 inches. Barley, oats and rye are grown in much the same areas except that winter wheat and rye are grown extensively in some areas where barley and oats will not survive when fall-sown and when spring-sown will not yield as well as winter wheat.

Because rye will survive more severe winters and will produce larger yields of grain on soils of low fertility than other cereals, it is the main food grain in certain regions of Europe and Asia. Oats are grown most extensively in the corn belt of North America because they fit so well into rotations with corn and clover, and in the cooler regions of Europe.

Rice is the principal cereal grown in the warmer humid areas of the temperate zone and in the tropics where water for irrigation is available and the land is of suitable topography and soil type for flooding. The crop is submerged in four to eight inches of water most of the time from seeding to maturity. It responds with high yields to the intensive methods of production practised in the densely populated areas of the orient where it forms the chief article of food.

Corn is grown mainly in the temperate zones in regions having a rainfall above eight inches for the three summer months or where the land is irrigated as in Egypt. Unknown outside the Americas before being taken to Europe by Columbus, it is now one of the principal crops in the Danube basin and in other regions of the old world.

Sorghum is a very important crop in parts of Africa, Asia and the southern great plains of the United States where it is too hot and dry for corn to be grown successfully.

Wheat, barley, oats, rye and rice are known also as the small grains. They are grown in close drills and are not cultivated during the growing season. Maize and sorghum are grown in rows about 42 inches apart and are cultivated during the growing season to control weeds. The coarse stalks and leaves of maize and sorghum either with or without the ears and heads are often fed to livestock as occasionally, also, are the finer-stemmed millet and oats. More often the small grains and millet are cut for hay before they are mature. Sometimes the small grains are used for fall, winter or spring pasture.

In the major cereal-growing regions of the world such as the prairies and plains of the United States and Canada, the grain belt of Australia, the pampas of Argentina and the Ukraine of Russia, preparation of the land, seeding and harvesting of the crop are done very efficiently by machinery which has been developed during the last hundred years. For example, it is estimated that in 1830 about 58 hours of man labour were required to grow, harvest, thresh and clean an acre of wheat yielding 20 bushels while with the machines in common use in 1940 only 3 man-hours of labour were required.

Like man, each of the cereal crops is subject to destructive diseases and also to drought and other adverse weather conditions which have caused great losses to growers and have sometimes resulted in famines. The ancient Greeks and Romans had special gods for cereal crops and held festivals to prevail upon them to protect the growing crops from rusts and smuts and to bring forth a good harvest. During the last 40 years scientists have devised methods for controlling many of these diseases and have developed improved varieties which are highly resistant to many of these diseases as well as to adverse weather conditions. Improved cultural practices and better varieties are adding hundreds of millions of bushels to cereal production each year. (*See* also BARLEY; MAIZE; MILLET; OATS; RICE; RYE; SORGHUM; WHEAT.)

(B. B. B.)

Cereals in Diet.—The dietary properties of the entire seed of wheat, rice, barley, rye, maize, oat and millet resemble each other in most respects. They are all deficient in calcium and vitamin A (except yellow maize), and the biological value of their protein moiety is lower than that of the proteins of milk, meats and eggs. When any one of these cereals is supplemented with calcium, vitamin A and a source of proteins of animal origin, it is rendered complete nutritionally.

Under the chronic conditions of scarcity of foods which prevailed generally in most parts of the world before the invention of modern farm machinery from 1840 on, cereals remained the most important food crop, although the yields were low because of inferiority of varieties and poor cultivation technique throughout Europe. With the development of modern machinery and improved selection through plant breeding, wheat production has been enormously increased. The price range of cereal products is small as compared with prices of the more expensive foods such as meats, milk, eggs, fruits and vegetables other than the potato. Bread grains and potatoes are the cheapest foods. Whenever economic conditions prevail which lower the incomes of families or increase the cost of foods, the tendency has been for people to subsist more largely on bread and potatoes. Since the potato is not constituted so as to make good the deficiencies of cereals, such dietaries as are largely derived from these sources are nutritionally inadequate. Much malnutrition in Europe and elsewhere in recent decades has been due to this cause.

Before the year 1879 the milling of wheat was done in the same manner as in the days of Moses, viz., between millstones. This precluded production of flour more refined than could be achieved by sifting out the coarser particles. With the invention of the roller mill, the wheat berry could be separated into more than 20 mill streams, each of different composition. Especially important from the nutritional standpoint is the removal of the germ and the outer layers of the wheat, which are, with the exception of the outermost or bran layer, the most nutritious parts of the grain. Modern white flour is essentially free from fat, which in whole meal grows rancid on long storage. It contains only the protein moiety of the grain which has the lowest nutritive value. In addition, most of the vitamins and mineral elements, except phosphorus and potassium, are milled out and go into stock feed. Modern white flour is milled for commercial expediency rather than in the interest of the people's health. Because of the hazards of marketing a more highly nutritious flour for breadmaking, it is clear that there is much to justify modern milling processes from the economic point of view. As a World War II measure Canada introduced a long extraction wheat flour known as Canada Approved Flour, which represented about 85% of the wheat berry as compared with ordinary flour which is refined to the least nutritious 70% of the wheat. Later, England adopted the practice of manufacture of a similar flour. Such flour is superior to ordinary white flour in nutritive value, being superior in vitamin and mineral nutrient values and in the quality of its proteins. In the interest of health it would be advisable to adopt such flour to the maximum extent to which commercial transport and storage of flour permit.

The practice of improving the quality of commercially baked bread by the use of skim milk instead of water in preparing the bread mix became general in the United States after World War I. As much as six per cent of nonfat milk solids in bread improves greatly the nutritive value of the loaf by compensating for all of the nutritive deficiencies of white flour except iron. Four to six per cent milk bread becomes stale less rapidly than does bread made without milk, crumbs less on cutting, and otherwise makes a highly desirable bread. This method of improving bread has become popular with bakers.

With the development of the synthetic production of several of the vitamins and consequent lowering of their cost, a movement was started to "enrich" bread made from white flour by the addition of thiamin, riboflavin, niacin and iron, with calcium and phosphorus additions optional. While it is true that such "enrichment" of a white flour bread may safeguard the health of people whose dietaries are of low quality, it is not clear that it is a wise policy to pay for the inclusion of these vitamins and iron in the diets of good to high quality which, there are good reasons for believing, represent those of a large majority of the people. An excess of vitamins has not been shown to be of benefit.

It is a wise policy to promote the manufacture of bread of the highest possible nutritive value. It would seem desirable nutritionally to include small percentages of wheat germ, corn (maize) germ, dried brewers' yeast, rice polishings, as well as the maximum amount of nonfat milk solids, in commercial bread formulae. Such a policy would go far toward justifying the milling of highly refined flour of good keeping quality. At the same time the nutritionally superior parts of the grain which have hitherto been used largely for animal feeding would be used to improve human nutrition.

Maize meal (corn meal) and corn grits are widely used as human foods, especially in the southern United States, in parts of Italy, Rumania, Egypt and elsewhere. Since maize contains about one-fifth as much niacin as does wheat, pellagra, which is due to niacin deficiency, has been common only where corn is extensively used as a bread grain or as corn-meal mush (polenta). The milling of maize by modern machinery produces a meal for human consumption which is as much depleted in nutrients as is white flour. Barley and rye are extensively used as human food only in areas where wheat does not yield well. These cereals are profitable agricultural crops in the thin sandy soils of northern Europe (rye) and in regions too hot and dry or too wet and cold for wheat. There are varieties of barley which yield a harvest under conditions too extreme for wheat production. Where rye and barley are used as bread grains they are not milled and refined as is wheat but are employed as essentially whole meal products. Oats, which are prepared for human consumption as rolled oats and oatmeal, are the only cereal marketed solely as a whole grain product. Machinery for their degermination has not been perfected.

Where wheat or other cereals are marketed for use as breakfast cereals, it is advisable to provide products which represent the entire seed because of their superior food values.

Rice is second only to wheat in the quantity grown and used as human food. Being the one cereal which grows in swampy land it forms the principal food of many millions of people in the warmer and wetter areas of the world. The flavour of whole rice is generally less relished than is that of polished rice. Polishing is desirable from the same commercial standpoint as is the refining of white flour. Both products keep well. Polishing removes the bran and aleurone layers from the surface of the kernel and also the germ. Polished rice closely resembles white patent wheat flour in dietary properties. Attempts have been made, and some progress achieved, in the distribution of "undermilled" rice and steamed rice. The former product contains some of the outer layers (silverskin) of the grain, and some germ. In the preparation of steamed rice the grain is steeped in water warm enough to facilitate permeation of the grain and gelatinization of the surface starch. These processes which serve to retain the thiamin content of rice have been promoted as a means of preventing the disease beri-beri which afflicts people whose diet is too largely derived from polished rice.

Sorghums, and also the seeds of several grasses popularly known as millets, are among the hardiest of the cereals in withstanding drought. They are extensively employed as human food in semiarid regions throughout the world. They are the least palatable of the cereals and are eaten from necessity rather than from choice. The use of these seed grains is most common in the U.S.S.R., northern Asia and Africa.

Because of great improvements in cereals through plant breeding, the use of appropriate machinery for the preparation of the soil, for planting, cultivation, harvesting and threshing of cereals, their production has been enormously increased within the past hundred years. They are our least expensive and most important foods as sources of calories, thiamin and protein, notwithstanding the latter is of rather poor quality as compared with foods of animal origin. Because of their dietary deficiencies, especially when refined derivatives of cereals are eaten, the ideal way to use cereals in the diet is in menus in which occur liberal amounts of milk and milk products, meats, eggs, fish, poultry, together with appropriate amounts of green and yellow vegetables and some fresh vegetable foods suitable for eating in the uncooked state for their antiscorbutic properties. The fact is well established that none of our common foods is complete nutritionally when eaten as the sole source of nutriment. The keynote to successful nutrition is the proper selection of foods, each deficient in one or more respects, but so constituted as to supplement each other's shortcomings and to make collectively a complete diet. (*See* also BREAD AND BREAD MANUFACTURE; FLOUR AND FLOUR MANUFACTURE.)

CEREBELLUM: *see* BRAIN; also EQUILIBRIUM, ANIMAL.

CEREMONIAL. In the military sense the prescribed drill and formations for certain specific occasions such as parades, reviews, guard duty, funerals, trooping the colours and lining streets, as distinct from drill applicable to field exercises.

CERES, goddess of the growth of food plants, worshipped, alone or with the god Cerus, over a considerable part of Italy. (Oscan *Keri—;* probably connected with *cre-are, cre-sco;?* "creatress"). Her cult was early overlaid by that of Demeter, who was widely worshipped in Sicily and Magna Graecia, *cf.* DEMETER. On the advice of the Sibylline Books, a cult of Ceres Liber and Libera was introduced into Rome in 496 B.C., to check a famine. Liber and Libera seem to represent the *Iakchos* and *Kore* of the Eleusinian cult. The ritual of this worship was largely if not wholly Greek. The temple, which was built on the Aventine in 493 B.C., and was of Etruscan shape but decorated by Greek artists, became a centre of plebeian activities, religious and political. Ceres was regarded as the patroness of the corn trade, which seems to have been early in plebeian hands. The chief festivals of this cult were:

(1) *Ludi Ceriales,* introduced before 202 B.C., and ultimately lasting from April 12–19;

(2) an annual festival, instituted before 217 B.C., celebrated in secret by the women and apparently dealing with the union of *Kore* and *Hades;*

(3) from 191 B.C. on, a fast (*ieiunium Cereris*), held every five years, but later every year on Oct. 4. All these are on Greek lines.

See Wissowa, *Religion und Kultus* (2nd ed.), pp. 192 *et seq.*, 297 *et seq.*

CERIGNOLA, a town of Apulia, Italy, in the province of Foggia, 26 mi. S.E. by rail from the town of Foggia. Pop. (1936) 37,163 (town); 39,540 (commune). It was rebuilt after a great earthquake in 1731. It has a considerable agricultural trade and also trade in merino and mattress wool. In 1503 the Spaniards under Gonzalo de Cordoba defeated the French under the duc de Nemours below the town—a victory which made the kingdom of Naples into a Spanish province in Italy. Cerignola lies on the Via Traiana between Herdoniae and Canusium.

CERIGOTTO, called locally Lius (anc. *Aegilia* or *Ogylos;* mod. official Gr. *Antikythera*), an island of Greece, between Cythera (Cerigo) and Crete, about 20 mi. from each. The inhabitants are mainly Cretan refugees, and in favourable seasons export wheat. It was long a resort of pirates. Close to its coast in 1900 an ancient ship was discovered, laden with bronze and marble statues. Cerigotto was occupied by Germany in 1941.

CERINTHUS (*c.* A.D. 100), a Christian heretic, known to St. John. Hippolytus (*Haer.* vii, 33) credits him with an Egyptian training, but there can be no truth in the notice given by Epiphanius (*Haer.* xxviii, 4) that Cerinthus had led the Judaizing opposition against Paul at Jerusalem.

According to Irenaeus (*Adv. haeres.*, I, 26, 1), Cerinthus taught that the world had been made by angels, from one of whom, the god of the Jews, the Israelites had received this imperfect law. The only New Testament writing which he accepted was a mutilated Gospel of Matthew. Jesus was the offspring of Joseph and Mary, and on Him at the baptism descended the Christ, the divine power, revealing the unknown Father, and endowing Him with miraculous power. This Christ left Jesus before the Passion and the resurrection. According to Philastrius and St. Epiphanius, Cerinthus admitted circumcision and the observance of the Sabbath. Gaius, the priest (*c.* 200), and Dionysius of Alexandria (*q.v.*) accused him of a crude form of Chiliasm. Cerinthus is a blend of judaizing Christian and Gnostic.

CERIUM (symbol Ce, atomic number 58, atomic weight 140.13) is the commonest metallic element of the rare-earth group and was discovered in 1803 by Martin Heinrich Klaproth and independently by Jons Jakob Berzelius and Wilhelm Hisinger; Berzelius named the element after the asteroid Ceres, discovered in 1801. The element is not really scarce in the earth's crust. Several investigators have estimated its abundance as being greater than that of tin, silver, mercury or tungsten. The metal has four stable isotopes: Ce^{136} (less than 0.2%), Ce^{138} (less than 0.3%), Ce^{140} (88.5%) and Ce^{142} (approximately 11%); radioactive isotopes are found among the fission products of thorium, uranium and plutonium. (*See* ISOTOPES; RADIOACTIVITY, ARTIFICIAL.) It occurs most abundantly in the minerals monazite, cerite, allanite and bastnasite, accompanied by other members of the rare-earth group. The latter mineral is found in extensive deposits in the western United States. The metal is formed by electrolysis of the anhydrous fused halides or by thermo-reduction with the alkali metals or with the alkaline-earth metals. It has an iron-gray colour and a hardness similar to that of tin or silver. The metal is slowly oxidized in air and reacts with boiling water, liberating hydrogen. Malleable and ductile, it possesses good thermal conductivity with a fairly high latent heat of fusion and melts at approximately 804° C. It combines readily with the halogens, is soluble in dilute acids and readily forms a hydride and a nitride. At room temperatures the metal is reported to exist in two allotropic forms. The α form (hexagonal close-packed, $a=3.65$ A [Angstrom unit $=10^{-8}$ cm.], $c=5.96$ A) has a calculated density $=6.78$ g. per cubic centimetre; the β or common form (cubic close-packed, $a=5.172$ A) has a calculated density $=6.731$ g. per cubic centimetre. A condensed cubic form exists at liquid air temperatures and has a density about 18% greater than the above. Undoubtedly other crystalline forms exist at high temperatures.

Cerium is a powerful reducing agent and, in the form of wire, burns brilliantly when heated. Since cerium is the only member of the rare-earth group which forms a higher series of compounds (other than the oxide), such as CeX_4, it is the most easily purified member of the group. These compounds upon hydrolysis form precipitates of basic salts practically free from the other rare earths. The purification is easily accomplished by carefully boiling a solution of the mixed nitrates and potassium bromate, with the gradual addition of ground marble to keep down the resulting acidity. The precipitated basic nitrate is washed with a 1% solution of nitric acid and may be further purified by repeating the process. A number of other methods were developed for separating cerium from the other rare earths based on the fact that it can be oxidized to the tetravalent state, in which it differs in properties from the other rare earths not so oxidized. Some promising procedures were found by which the tetravalent cerium salts are removed by solvent extraction.

Ceric oxide (CeO_2) is commonly formed when the cerium salts of the volatile acids are roasted in air. The pure oxide is a nearly white powder which is insoluble in nitric and hydrochloric acids but is soluble in sulphuric acid. The corresponding ceric salts, such as $Ce(SO_4)_2$, possess a yellow or orange-red colour; they are diamagnetic or at most show only a slight residual paramagnetism. The cerous salts, such as $Ce_2(SO_4)_3$, are more stable, are colourless, show no sharp-lined absorption spectra in the visible or ultra-violet regions and are paramagnetic.

Cerium has several practical uses. The tetravalent salts are employed as oxidizing agents in analytical chemistry and as therapeutic agents. Cerium nitrate finds application in the manufacture of Welsbach gas mantles and in the ceramic and textile industries. It is an ingredient of carbon-impregnated arcs used by the motion-picture industry. Cerium metal is used in metallurgy to form alloys, the commonest being misch metal. This alloy is usually manufactured directly from the crude rare earths and contains approximately 45% to 50% cerium, 22% to 25% lanthanum, 15% to 17% neodymium, 8% to 10% praseodymium, terbium, yttrium and samarium, 0 to 5% iron and 0.1% to 0.3% silicon. Since the properties of the other rare-earth metals are similar to those of cerium, this alloy is generally used in place of crude cerium. Misch metal and metallic cerium are good reducing agents and oxidize rapidly. These metals are employed as active deoxidizers or "getters" in the iron industry and are well known as scavengers and purifiers in various types of foundry melts. They have also found considerable application in the light metal industry, since they tend to give sound castings of aluminum and magnesium when present in small amounts. They are employed in pyrophoric flints and are valuable as a constituent of the "getters" used in the manufacture of vacuum tubes and similar equipment. Cerium oxide is used as an opacifier in the making of porcelain coatings for signs. It is also employed as an abrasive in polishing glass, for which purpose it has properties superior to those of rouge. (*See* RARE EARTHS.) (F. H. SP.)

CERNUSCHI, HENRI (1821–1896), Italian politician and economist, was born at Milan. He played a part in the revolutionary movement and was compelled to leave Italy in 1850. He then settled in France, where he made a large fortune. Cernuschi is best known as an ardent champion of bimetallism, and the word itself is commonly supposed to have originated with him—at least in its English form it is first found in his *Silver Vindicated* (1876).

Among his other works may be mentioned *Mécanique de l'échange* (1861); *Le Bimétallisme en Angleterre* (1879); *Le Grand procès de l'Union latine* (1884); *Illusion des sociétés coopératives* (1886).

CEROGRAPHY, the art of painting in wax; from the Gr. κηρός, wax, and γράφειν, to write. (*See* ENCAUSTIC PAINTING.) It is also the name of a wax process employed in printing in which engraved sheets of wax are used after they have been electrotyped.

CERRO GORDO. A mountain pass, 60 mi. N.W. of Veracruz, Mex., along the National highway from the coast to the capital of Mexico.

Here Gen. Winfield Scott in his advance to Mexico City during the war between the United States and Mexico (1846–48) met his first determined resistance. Brig. Gen. D. E. Twiggs's leading column was stopped by the river ravine on his left, fire from the emplaced Mexican artillery on the centre heights, and rugged terrain on his right (April 12, 1847).

After Scott arrived (April 14) several later-prominent officers among them Capt. Robert E. Lee, were sent out on reconnaissance. Lee located a trail leading to the rear of the left flank of the Mexican army but was forced to hide in their midst behind a fallen log for several hours before he could return. As the result of this reconnaissance, General Scott made plans to divide his troops and concentrate a major attack by using the natural barrier of the rough country to hide his sweep around the Mexican left. A simultaneous frontal advance was also to be made.

His force numbered about 8,500 as against approximately 12,000 Mexicans under Gen. Antonio Lopez de Santa Anna. On April 17 Twiggs, guided by Lee, advanced and occupied the prominent hill La Atalaya according to plan. Instead of waiting to attack at the same time with Gen. James Shields's brigade, which had a longer distance to march, Twiggs's impetuously advancing troops prematurely attempted to capture the commanding position El Telégrafo, beyond La Atalaya, but were repulsed. Shields's brigade, with artillery, came into position during the evening through a hampering rain. The next morning, April 18, the attack on El Telégrafo was renewed, and cheering troops under Col. W. S. Harney fought their way up the slope, capturing the crest by hand-to-hand fighting. The parallel seizure of the Spur by Col. Bennet Riley's troops and the emergence of Shields's brigade into the open near Santa Anna's main camp caused the Mexican army, afraid of being cut off, to flee.

The planned frontal attack was made by Brig. Gen. G. J. Pillow against the emplaced batteries on the three ridges immediately in front of the American army; it was unsuccessful.

The Mexican loss was 40 cannon, 4,000 muskets, about 4,000 prisoners and about 1,100 casualties. The American loss is given as 63 killed and 353 wounded.

BIBLIOGRAPHY.—J. H. Smith, *The War With Mexico,* vol. ii (New York, 1919); A. H. Bill, *Rehearsal for Conflict* (New York, 1947); R. S. Henry, *The Story of the Mexican War* (Indianapolis, 1950).
(G. J. S.)

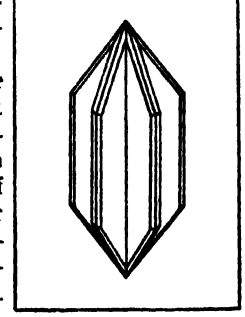
CERTALDO, a town of Tuscany, It., in the province of Florence, 35 mi. S.S.W. by rail and 18 mi. direct from the town of Florence. Pop. (1951) 12,089 (commune). It was the home of the family of Giovanni Boccaccio, who died and was buried there in 1375. His house of brick was restored in 1823. A statue of him was erected in the principal square in 1875. The Palazzo Pretorio, or del Vicariato, the residence of the Florentine governors, restored

to its original condition, has a picturesque façade and court.

CERTHIIDAE: *see* TREE-CREEPER.

CERTIFICATE OF DEPOSIT, a written receipt from a bank acknowledging the deposit therein of a certain sum of money. Under such certificate, money may be deposited either on a demand basis or a time basis, but in either case it cannot be drawn against by cheque. To withdraw funds deposited under a certificate of deposit it is necessary to present the certificate itself, properly endorsed.

In the United States certificates of deposit are negotiable when properly endorsed and are usually acceptable as security for loans. (*See* WARRANT.)



CERTIFIED CHEQUE, a cheque regularly drawn against a depositor's account in a bank but having stamped or written on the face the word "certified" or "accepted," or the phrase "good when properly indorsed," or "good through clearing house," or some other expression commonly used, and the signature of a bank official, usually a cashier or paying teller, qualified to make certifications. The certification is the bank's guarantee that the signature of the drawer is genuine and that there are and will be sufficient funds to his credit to pay the cheque. A certified cheque becomes an obligation of the bank itself instead of merely an order upon the bank by the drawer. Immediately upon the certification of a cheque, the amount certified is set aside from the drawer's account specially for the purpose of paying the cheque; and other cheques which may be presented ahead of that certified will not be allowed to withdraw the funds so segregated. The advantage of the certified cheque is that it will not be refused payment on the ground of "no funds," or "not sufficient funds."

A cheque may be certified at the request of either the drawer or a holder. If certified at the request of a holder, however, both the drawer and the indorsers, if any, are released from obligation and the holder must look for payment to the bank alone, and the bank is absolutely liable unless the cheque was "raised," either before or after the certification. When a bank certifies a cheque at the request of the drawer, the latter is not released from liability, and if the bank should fail before the cheque is presented for payment, the holder will have recourse against the drawer.

(J. H. B.)

CERTIFIED PUBLIC ACCOUNTANT, a U.S. designation the use of which is restricted by state law to accountants who have met the legal requirements of the state or states in which they seek recognition. In addition to meeting certain educational and professional demands, candidates must also submit to written examinations in the subjects prescribed. Upon fulfilling the conditions of the particular state, the accountant receives a certificate which entitles him to use the expression "certified public accountant" after his name, or the abbreviation C.P.A.

There are no regulations, either state or federal, which prohibit an accountant who has not received a certificate from engaging in professional practice, but certain assignments which are made by courts of law can be handled only by certified public accountants; without this certificate, accountants are finding it increasingly difficult to gain a footing in the profession. (*See* ACCOUNTING.)

CERUSSITE TWIN
A native lead ore which occurs in three colours, in solid or granular form

CERUSSITE, a mineral consisting of lead carbonate, $PbCO_3$, and forming an important ore of lead; it contains 77.5% of the metal. The name is derived from the Latin *cerussa*, "white lead." It crystallizes in the orthorhombic system, and often forms pseudo-hexagonal twins like those of aragonite, with which it is isomorphous. It also occurs in compact granular or fibrous forms. It is usually colourless or white, sometimes grey or greenish, and is usually more or less transparent: some well-formed crystals have a brilliant lustre. Its hardness is 3–3.5 and density 6.5. It effervesces with dilute nitric acid. Cerussite occurs in large quantities in the upper oxidized portions of lead deposits. (CL. F.)

CERUTTI, GIUSEPPE (1738–1792), French author and politician, was born at Turin. He taught at the Jesuit college at Lyons and wrote an *Apologie* (1762) for his order. His *Mémoire pour le peuple français* (1788) advocates the claims of the *tiers état*. He was a member of the legislative assembly and a friend of Mirabeau, whose funeral oration he pronounced. He, with Rabaut Saint-Étienne and Grouvelle, founded the weekly sheet *La Feuille villageoise*, addressed to the villages of France to inform them of the progress of the Revolution.

On the *Mémoire pour le peuple français, see* F. A. Aulard in *La Révolution française*, tom. xv. (1888).

CERVANTES SAAVEDRA, MIGUEL DE (1547–1616), Spanish novelist, playwright and poet, was born at Alcalá de Henares. He was the second son of Rodrigo de Cervantes, an apothecary and surgeon, and Leonor de Cortinas. The exact date of Cervantes' birth is not recorded; he was baptized on Oct. 9, 1547, in the church of Santa María la Mayor at Alcalá. There are indications that Rodrigo de Cervantes resided at Valladolid in 1554, at Madrid in 1561, at Seville in 1564–65, and at Madrid from 1566 onwards. It may be assumed that his family accompanied him, and it seems likely that either at Valladolid or at Madrid Cervantes saw the famous actor, manager and dramatist, Lope de Rueda, of whose performances he speaks enthusiastically in the preface to his plays. In 1569 a Madrid schoolmaster, Juan López de Hoyos, issued a work commemorative of Philip II's third wife, Isabel de Valois, who had died on Oct. 3, 1568. This volume, entitled *Hystoria y relación verdadera de la enfermedad, felicissimo tránsito, y sumptuosas exequias fúnebres de la Serenissima Reyna de España Doña Isabel de Valoys, nuestra Señora*, contains six contributions by Cervantes: a sonnet, four redondillas, and an elegy. López de Hoyos introduced Cervantes as "our dear and beloved pupil," and the elegy was dedicated to Cardinal Espinosa "in the name of the whole school." It has been inferred that Cervantes was educated by López de Hoyos, but this conclusion is untenable, for López de Hoyos' school was not opened till 1567. On Oct. 13, 1568 Giulio Acquaviva reached Madrid charged with a special mission to Philip II; he left for Rome on Dec. 2, and Cervantes is supposed to have accompanied him. This conjecture is based solely on a passage in the dedication of the *Galatea*, where the writer speaks of having been "camarero to Cardinal Acquaviva at Rome." There is, however, no reason to think that Cervantes met Acquaviva in Madrid; the probability is that he enlisted as a supernumerary towards the end of 1568, that he served in Italy, and there entered the household of Acquaviva, who had been raised to the cardinalate on May 17, 1570. All that is known with certainty is that Cervantes was in Rome at the end of 1569, for on Dec. 22 of that year the fact was recorded in an official information lodged by Rodrigo de Cervantes with a view to proving his son's legitimacy and untainted Christian descent.

There is evidence, more or less, that he enlisted in the regular army in 1570; in 1571 he was serving as a private in the company commanded by Captain Diego de Urbina which formed part of Miguel de Moncada's famous regiment, and on Sept. 16 he sailed from Messina on board the "Marquesa," which formed part of the armada under Don John of Austria. At the battle of Lepanto (Oct. 7, 1571) the "Marquesa" was in the thickest of the conflict. As the fleet came into action Cervantes lay below, ill with fever; but, despite the remonstrances of his comrades he vehemently insisted on rising to take his share in the fighting and was posted with 12 men under him in a boat by the galley's side. He received three gunshot wounds, two in the chest, and one which permanently maimed his left hand—"for the greater glory of the right," in his own phrase. On Oct. 30, the fleet returned to Messina, where Cervantes went into hospital, and during his convalescence received grants-in-aid amounting to 82 ducats. On April 29, 1572 he was transferred to Captain Manuel Ponce de León's company in Lope de Figueroa's regiment; he shared in the indecisive naval engagement off Navarino on Oct. 7, 1572, in the capture of Tunis on Oct. 10, 1573, and in the unsuccessful expedition to relieve the Goletta in the autumn of 1574. The rest of his military service was spent in garrison at Palermo and Naples, and shortly after the arrival of Don John at Naples

on June 18, 1575, Cervantes was granted leave to return to Spain; he received a recommendatory letter from Don John to Philip II., and a similar testimonial from the duke de Sessa, viceroy of Sicily. Armed with these credentials, Cervantes embarked on the "Sol" to push his claim for promotion in Spain.

On Sept. 26, 1575, near Les Trois Maries off the coast of Marseilles, the "Sol" and its companion ships the "Mendoza" and the "Higuera" encountered a squadron of Barbary corsairs under Arnaut Mami; Cervantes, his brother Rodrigo and other Spaniards were captured, and were taken as prisoners to Algiers. Cervantes became the slave of a Greek renegade named Dali Mami, and, as the letters found on him were taken to prove that he was a man of importance in a position to pay a high ransom, he was put under special surveillance. In 1576 he induced a Moor to guide him and other Christian captives to Oran; the Moor deserted them on the road, the baffled fugitives returned to Algiers, and Cervantes was treated with additional severity. In the spring of 1577 two priests of the Order of Mercy arrived in Algiers with a sum of 300 crowns entrusted to them by Cervantes' parents; the amount was insufficient to free him, and was spent in ransoming his brother Rodrigo. Cervantes made another attempt to escape in Sept. 1577, but was betrayed by the renegade whose services he had enlisted. On being brought before Hassan Pasha, the viceroy of Algiers, he took the blame on himself, and was threatened with death; struck, however, by the heroic bearing of the prisoner, Hassan remitted the sentence, and bought Cervantes from Dali Mami for 500 crowns. In 1577 the captive addressed to the Spanish secretary of State, Mateo Vázquez, a versified letter suggesting that an expedition should be fitted out to seize Algiers; the project, though practicable, was not entertained. In 1578 Cervantes was sentenced to 2,000 strokes for sending a letter begging help from Martín de Córdoba, governor of Oran; the punishment was not, however, inflicted on him. Meanwhile his family were not idle. In March, 1578 his father presented a petition to the king setting forth Cervantes' services; the duke de Sessa repeated his testimony to the captive's merits; in the spring of 1579 Cervantes' mother applied for leave to export 2,000 ducats' worth of goods from Valencia to Algiers, and on July 31, 1579 she gave the Trinitarian monks, Juan Gil and Antón de la Bella, a sum of 250 ducats to be applied to her son's ransom. On his side Cervantes was indefatigable, and towards the end of 1579 he arranged to secure a frigate; but the plot was revealed to Hassan by Juan Blanco de Paz, a Dominican monk, who appears to have conceived an unaccountable hatred of Cervantes. Once more the conspirator's life was spared by Hassan, who, it is recorded, declared that "so long as he had the maimed Spaniard in safe keeping, his Christians, ships and city were secure." On May 29, 1580 the two Trinitarians arrived in Algiers: they were barely in time, for Hassan's term of office was drawing to a close, and the arrangement of any ransom was a slow process, involving much patient bargaining. Hassan refused to accept less than 500 gold ducats for his slave; the available funds fell short of this amount, and the balance was collected from the Christian traders of Algiers. Cervantes was already embarked for Constantinople when the money was paid on Sept. 19, 1580. The first use that he made of his liberty was to cause affidavits of his proceedings at Algiers to be drawn up; he sailed for Spain towards the end of October, landed at Denia in November, and made his way to Madrid. He signed an information before a notary in that city on Dec. 18, 1580.

PATIO OF CERVANTES' HOUSE

These dates prove that he cannot, as is often alleged, have served under Alva in the Portuguese campaign of 1580: that campaign ended with the battle of Alcántara on Aug. 25, 1580. It seems certain, however, that he visited Portugal soon after his return from Algiers, and in May 1581, he was sent from Thomar on a mission to Oran. Construed literally, a formal statement of his services, signed by Cervantes on May 21, 1590 makes it appear that he served in the Azores campaigns of 1582–83; but the wording of the document is involved, the claims of Cervantes are confused with those of his brother Rodrigo (who was promoted ensign at the Azores), and on the whole it is doubtful if he took part in either of the expeditions under Santa Cruz. In any case, the stories of his residence in Portugal, and of his love affairs with a noble Portuguese lady, who bore him a daughter, are simple inventions. From 1582–83 to 1587 Cervantes seems to have written copiously for the stage, and in the Adjunta al Parnaso he mentions several of his plays as "worthy of praise"; these were *El Trato de Argel, La Numancia, La Gran Turquesa, La Batalla naval, La Jerusalén, La Amaranta ó la de Mayo, El Bosque amoroso, La Unica y Bizarra Arsinda*—"and many others which I do not remember, but that which I most prize and pique myself on was and is, one called *La Confusa,* which, with all respect to as many sword-and-cloak plays as have been staged up to the present, may take a prominent place as being good among the best." Of these only *El Trato de Argel* and *La Numancia* have survived, and, though *La Numancia* contains many fine rhetorical passages, both plays go to prove that the author's genius was not essentially dramatic. In Feb. 1584 he obtained a licence to print a pastoral novel entitled *Primera parte de la Galatea,* the copyright of which he sold on June 14, to Blas de Robles, a bookseller at Alcalá de Henares, for 1,336 *reales.* On Dec. 12 he married Catalina de Palacios Salazar y Vozmediano of Esquivias, 18 years his junior. The *Galatea* was published in the spring of 1585. It was only twice reprinted—once at Lisbon (1590), and once at Paris (1611)—during the author's lifetime; but it won him a measure of repute; it was his favourite among his books, and during the 30 years that remained to him he repeatedly announced the second part which is promised conditionally in the text. However, it is not greatly to be regretted that the continuation was never published, though the *Galatea* is interesting as the first deliberate bid for fame on the part of a great genius. It is an exercise in the pseudo-classic literature introduced into Italy by Sannazaro, and transplanted to Spain by the Portuguese Montemōr; and, ingenious or eloquent as the Renaissance prose-pastoral may be, its innate artificiality stifles Cervantes' rich and glowing realism. He himself recognized its defects; with all his weakness for the *Galatea,* he ruefully allows that "it proposes something and concludes nothing." Its comparative failure was a serious matter for Cervantes who had no other resource but his pen; his plays were probably less successful than his account of them would imply, and at any rate play-writing was not at this time a lucrative occupation in Spain. No doubt the death of his father on June 13, 1585, increased the burden of Cervantes' responsibilities; and the dowry of his wife, as appears from a document dated Aug. 9, 1586, consisted of nothing more valuable than five vines, an orchard, some household furniture, four beehives, 45 hens and chickens, one cock and a crucible.

It had become evident that Cervantes could not gain his bread by literature, and in 1587 he went to Seville to seek employment in connection with the provisioning of the Invincible Armada. He was placed under the orders of Antonio de Guevara, and before Feb. 24 was excommunicated for excessive zeal in collecting wheat at Ecija. During the next few months he was engaged in gathering stores at Seville and the adjacent district, and after the defeat of the Armada he was retained as commissary to the galleys. Tired of the drudgery, and without any prospect of advancement, on May 21, 1590 Cervantes drew up a petition to the king, recording his services and applying for one of four posts then vacant in the American colonies; a place in the department of public accounts in New Granada, the governorship of Soconusco in Guatemala, the position of auditor to the galleys at Cartagena, or that of *corregidor* in the city of La Paz. The petition was referred to the Council of the Indies, and was annotated with the words: "Let him look for something nearer home." In Nov. 1590 he was in such straits that he borrowed money to buy himself a suit of clothes, and in Aug. 1592 his sureties were called upon to make good a deficiency of 795 *reales* in his accounts. His thoughts turned to literature once more, and on Sept. 5, 1592, he signed a

contract with Rodrigo Osorio undertaking to write six plays at 50 ducats each, no payment to be made unless Osorio considered that each of these pieces was "one of the best ever produced in Spain." Nothing came of this agreement, and it appears that, between the date of signing it and Sept. 19, Cervantes was imprisoned (for reasons unknown to us) at Castro del Río. He was speedily released, and continued to perquisition as before in Andalusía; but his literary ambitions were not dead, and in May 1595 he won the first prize (three silver spoons) at a poetical tourney held in honour of St. Hyacinth at Saragossa. Shortly afterwards Cervantes found himself in difficulties with the exchequer officials. He entrusted a sum of 7,400 *reales* to a merchant named Simón Freire de Lima with instructions to pay the amount into the treasury at Madrid; the agent became bankrupt and absconded, leaving Cervantes responsible for the deficit. By some means the money was raised, and the debt was liquidated on Jan. 21, 1597. But Cervantes' position was shaken, and his unbusinesslike habits lent themselves to misinterpretation. On Sept. 6, 1597 he was ordered to find sureties that he would present himself at Madrid within 20 days, and there submit to the exchequer vouchers for all official moneys collected by him in Granada and elsewhere. No such sureties being available, he was committed to Seville gaol, but was released on Dec. 1, on condition that he complied with the original order of the court within 30 days. He was apparently unable to find bail, was dismissed from the public service, and sank into extreme poverty. During a momentary absence from Seville in Feb. 1599, he was again summoned to Madrid by the treasury, but does not appear to have obeyed; it is only too likely that he had not the money to pay for the journey. There is some reason to think that he was imprisoned at Seville in 1602, but nothing positive is known of his existence between 1600 and Feb. 8, 1603: at the latter date he seems to have been at Valladolid, to which city Philip III. had removed the court in 1601.

Since the publication of the *Galatea* in 1585 Cervantes' contributions to literature had been limited to occasional poems. In 1591 he published a ballad in Andrés de Villalta's *Flor de varios y nuevos romances;* in 1595 he composed a poem, already mentioned, to celebrate the canonization of St. Hyacinth; in 1596 he wrote a sonnet ridiculing Medina Sidonia's tardy entry into Cadiz after the English invaders had retired, and in the same year his sonnet lauding Santa Cruz was printed in Cristóbal Mosquera de Figueroa's *Comentario en breve compendio de disciplina militar;* to 1597 is assigned a sonnet (the authenticity of which is disputed) commemorative of the poet Herrera; in 1598 he wrote two sonnets and a copy of quintillas on the death of Philip II.; and in 1602 a complimentary sonnet from his pen appeared in the second edition of Lope de Vega's *Dragontea.* Curiously enough, it is by Lope de Vega that *Don Quixote* is first mentioned. Writing to an unknown correspondent (apparently a physician) on Aug. 14, 1604, Lope de Vega says that "no poet is as bad as Cervantes, nor so foolish as to praise *Don Quixote,*" and he goes on to speak of his own plays as being odious to Cervantes. It is obvious that the two men had quarrelled since 1602, and that Lope de Vega smarted under the satire of himself and his works in Cervantes' forthcoming book; *Don Quixote* may have been circulated in manuscript, or may even have been printed before the official licence was granted on Sept. 26, 1604. It was published early in 1605, and was dedicated to the seventh duke de Béjar in phrases largely borrowed from the dedication in Herrera's edition (1580) of Garcilaso de la Vega, and from Francisco de Medina's preface to that work.

The mention of Bernardo de la Vega's *Pastor de Iberia* shows that the sixth chapter of *Don Quixote* cannot have been written before 1591. In the prologue Cervantes describes his masterpiece as being "just what might be begotten in a gaol"; on the strength of this passage, it has been thought that he conceived the story, and perhaps began writing it, during one of his terms of imprisonment at Seville between 1597 and 1602. Within a few weeks of its publication at Madrid, three pirated editions of *Don Quixote* were issued at Lisbon; a second authorized edition, imperfectly revised, was hurried out at Madrid; and another reprint appeared at Valencia with an *aprobacion* dated July 18, 1605. With the exception of Alemán's *Guzmán de Alfarache,* no Spanish book of the period was more successful. Modern criticism is prone to regard *Don Quixote* as a symbolic, didactic or controversial work intended to bring about radical reforms in Church and State. Such interpretations did not occur to Cervantes' contemporaries, nor to Cervantes himself. There is no reason for rejecting his plain statement that his main object was to ridicule the romances of chivalry, which in their latest developments had become a tissue of tiresome absurdities. It seems clear that his first intention was merely to parody these extravagances in a short story; but as he proceeded the immense possibilities of the subject became more evident to him, and he ended by expanding his work into a brilliant panorama of Spanish society as it existed during the 16th century. Nobles, knights, poets, courtly gentlemen, priests, traders, farmers, barbers, muleteers, scullions and convicts; accomplished ladies, impassioned damsels, Moorish beauties, simple-hearted country girls and kindly kitchen-wenches of questionable morals—all these are presented with the genial fidelity which comes of sympathetic insight. The immediate vogue of *Don Quixote* was due chiefly to its variety of incident, to its wealth of comedy bordering on farce, and perhaps also to its keen thrusts at eminent contemporaries; its reticent pathos, its large humanity, and its penetrating criticism of life were less speedily appreciated.

Meanwhile on April 12, 1605, Cervantes authorized his publisher to proceed against the Lisbon booksellers who threatened to introduce their piratical reprints into Castile. By June the citizens of Valladolid already regarded Don Quixote and Sancho Panza as proverbial types. Practically nothing is known of Cervantes' life between 1605 and 1608. A *Relación* of the festivities held to celebrate the birth of Philip IV., and a certain *Carta á don Diego Astudillo Carrillo* have been erroneously ascribed to him; during these three years he apparently wrote nothing beyond three sonnets, and one of these is of doubtful authenticity. The depositions of the Valladolid enquiry show that he was living in poverty five months after the appearance of *Don Quixote,* and the fact that he borrowed 450 *reales* from his publisher before Nov. 1607 would convey the idea that his position improved slowly, if at all. But it is difficult to reconcile this view of his circumstances with the details concerning his illegitimate daughter revealed in documents recently discovered. Isabel de Saavedra was stated to be a spinster when arrested at Valladolid in June, 1605; the settlement of her marriage with Luis de Molina in 1608 describes her as the widow of Diego Sanz, as the mother of a daughter eight months old, and as owning house-property of some value. These particulars are perplexing, and the situation is further complicated by the publication of a deed in which Cervantes declares that he himself is the real owner of this house property, and that his daughter has merely a life-interest in it. This claim may be regarded as a legal fiction; it cannot easily be reconciled with Cervantes' statement towards the end of his life, that he was dependent on the bounty of the count de Lemos and of Bernardo de Sandoval, cardinal-archbishop of Toledo. In 1609 he joined the newly founded confraternity of the Slaves of the Most Blessed Sacrament; in 1610 Lemos was appointed viceroy of Naples, and Cervantes was keenly disappointed at not being chosen to accompany his patron. In 1611 he joined the Academia Selvaje, and there appears to have renewed his former friendly relations with Lope de Vega; in 1613 he dedicated his *Novelas exemplares* to the count de Lemos, and disposed of his rights for 1,600 *reales* and 24 copies of the book. The 12 tales in this volume, some of them written very much later than others, are of unequal merit, but they contain some of the writer's best work, and the two picaresque stories—*Rinconete y Cortadillo* and the *Coloquio de los perros*—are superb examples of their kind, and would alone entitle Cervantes to take rank with the greatest masters of Spanish prose. In 1614 he published the *Viage del Parnaso,* a burlesque poem suggested by the *Viaggio in Parnaso* (1582) of the Perugian poet Cesare Caporali. It contains some interesting autobiographical passages, much flattery of contemporary poetasters, and a few happy satirical touches; but, though

it is Cervantes' most serious bid for fame as a poet, it has seldom been reprinted, and would probably have been forgotten but for an admirably humorous postscript in prose which is worthy of the author at his best. In the preface to his *Ocho comedias y ocho entremeses nuevos* (1615) he good-humouredly admits that his dramatic works found no favour with managers, and, when this collection was first reprinted (1749), the editor advanced the fantastic theory that the *comedias* were deliberate exercises in absurdity, intended to parody the popular dramas of the day. This view cannot be maintained, but a sharp distinction must be drawn between the eight set plays and the eight interludes; with one or two exceptions, the *comedias* or set plays are unsuccessful experiments in Lope de Vega's manner, while the *entremeses* or interludes, particularly those in prose, are models of spontaneous gaiety and ingenious wit.

In the preface to the *Novelas exemplares* Cervantes had announced the speedy appearance of the sequel to *Don Quixote* which he had vaguely promised at the end of the first part. He was at work on the 59th chapter of his continuation when he learned that he had been anticipated by Alonso Fernandez de Avellaneda of Tordesillas, whose *Segundo tomo del ingenioso hidalgo don Quixote de la Mancha* was published at Tarragona in 1614. On the assumption that Fernandez de Avellaneda is a pseudonym, this spurious sequel has been ascribed to the king's confessor, Luis de Aliaga, to Cervantes' old enemy, Blanco de Paz, to his old friend, Bartolomé Leonardo de Argensola, to the three great dramatists, Lope de Vega, Tirso de Molina and Ruiz de Alarcón, to Alonso Fernandez, to Juan José Martí, to Alfonso Lamberto, to Luis de Granada, and probably to others. Some of these attributions are manifestly absurd (for example, Luis de Granada died 17 years before the first part of *Don Quixote* was published) and all of them are improbable conjectures; if Avellaneda be not the real name of the author, his identity is still undiscovered. His book is not devoid of literary talent and robust humour, and possibly he began it under the impression that Cervantes was no more likely to finish *Don Quixote* than to finish the *Galatea*. He should, however, have abandoned his project on reading the announcement in the preface to the *Novelas exemplares;* what he actually did was to disgrace himself by writing an insolent preface taunting Cervantes with his physical defects, his moral infirmities, his age, loneliness and experiences in gaol. He was too intelligent to imagine that his continuation could hold its own against the authentic sequel, and malignantly avowed his intention of being first in the field and so spoiling Cervantes' market. It is quite possible that *Don Quixote* might have been left incomplete but for this insulting intrusion; Cervantes was a leisurely writer and was, as he states, engaged on *El Engaño á los ojos, Las Semanas del Jardín* and *El Famoso Bernardo,* none of which has been preserved. Avellaneda forced him to concentrate his attention on his masterpiece, and the authentic second part of *Don Quixote* appeared towards the end of 1615. The last 14 chapters are damaged by undignified denunciations of Avellaneda; but, apart from this, the second part of *Don Quixote* is an improvement on the first. The humour is more subtle and mature; the style is of more even excellence; and the characters of the bachelor and of the physician, Pedro Recio de Agüero, are presented with a more vivid effect than any of the secondary characters in the first part. Cervantes had clearly profited by the criticism of those who objected to "the countless cudgellings inflicted on Señor Don Quixote," and to the irrelevant interpolation of extraneous stories in the text. Don Quixote moves through the second part with unruffled dignity; Sancho Panza loses something of his rustic cunning, but he gains in wit, sense and manners. The original conception is unchanged in essentials, but it is more logically developed, and there is a notable progress in construction. Cervantes had grown to love his knight and squire, and he understood his own creations better than at the outset; more completely master of his craft, he wrote his sequel with the unfaltering confidence of a renowned artist bent on sustaining his reputation.

The first part of *Don Quixote* had been reprinted at Madrid in 1608; it had been produced at Brussels in 1607 and 1611, and at Milan in 1610; it had been translated into English in 1612 and into French in 1614. Cervantes was celebrated in and out of Spain, but his celebrity had not brought him wealth. The members of the French special embassy, sent to Madrid in Feb. 1615, under the Commandeur de Sillery, heard with amazement that the author of the *Galatea,* the *Novelas exemplares* and *Don Quixote* was "old, a soldier, a gentleman and poor." He now worked assiduously at *Los Trabajos de Persiles y Sigismunda,* which, as he had jocosely prophesied in the preface to the second part of *Don Quixote,* would be "either the worst or the best book ever written in our tongue." It is the most carefully written of his prose works, and the least animated or attractive of them; signs of fatigue and of waning powers are unmistakably visible. On April 18, 1616, Cervantes received the sacrament of extreme unction; next day he wrote the dedication of *Persiles y Sigismunda* to the count de Lemos—the most moving and gallant of farewells. He died at Madrid in the Calle del León on April 23; he was borne from his house "with his face uncovered," according to the rule of the Tertiaries of St. Francis, and on April 24 was buried in the church attached to the convent of the Trinitarian nuns in the Calle de Cantarranas. There he rests (the story of his remains being removed in 1633 to the Calle del Humilladero has no foundation in fact) but the exact position of his grave is unknown. Early in 1617 *Persiles y Sigismunda* was published, and passed through eight editions within two years; but the interest in it soon died away, and it was not reprinted between 1625 and 1719. Cervantes' wife died without issue on Oct. 31, 1626; his natural daughter, who survived both the child of her first marriage and her second husband, died on Sept. 20, 1652. Cervantes is represented solely by his works. The *Novelas exemplares* alone would give him the foremost place among Spanish novelists; *Don Quixote* entitles him to rank with the greatest writers of all time: "children turn its leaves, young people read it, grown men understand it, old folk praise it." It has outlived all changes of literary taste, and is even more popular to-day than it was three centuries ago.

CERVERA, PASCUAL CERVERA Y TOPETE (1839–1909), Spanish admiral, was born at Medina Sidonia. As a sub-lieutenant he took part in the naval operations on the coast of Morocco during the campaign of 1859–60. Then he was engaged in operations in the Sulu Islands and the Philippines, and afterwards on the West Indian station during the first Cuban War (1868–78), returning to Spain in 1873 to serve on the Basque coast against the Carlists. He distinguished himself in defending the Carraca arsenal near Cadiz against the Federals in 1873. He became minister of marine in 1892, in a cabinet presided over by Sagasta, but he withdrew from the cabinet when he found that his colleagues, from political motives, declined to support his reforms and, on the other hand, unwisely cut down the naval estimates. When in 1898 the Spanish-American War (*q.v.*) broke out, he was chosen to command a squadron composed of four first-class cruisers, which was totally destroyed by the superior

forces of the enemy. After the war, Cervera and his captains were honourably acquitted by the supreme naval and military court of the realm. In 1901 he became vice-admiral, in 1902 chief of staff of the Spanish navy, and in 1903 was made life senator.

See A. Risco, *Apuntes Biograficos del Cervera y Topete* (Toledo, 1920).

CESAREVICH (better TSESAREVICH), the title until 1917 of the heir-apparent to the Russian throne. The full official title was *Nasliednik Tsarevich; i.e.*, "heir of Caesar," and in Russian the heir to the throne was commonly called simply *Nasliednik*, the word *Tsarevich* never being used alone. *Tsarevich* means any son of the emperor. The Cesarewitch handicap race at Newmarket, founded in 1839, was named after the prince, afterwards Alexander II. of Russia, who paid a state visit to England that year.

CESARI, GIUSEPPE (1568?–1640), called Il Cavaliere d'Arpino, also Il Giuseppino, Italian painter, born in Rome. His father was a native of Arpino. Cesari ranks as the head of the so-called "Idealists" of his period, as opposed to the "Naturalists," of whom Michelangelo da Caravaggio was the leader. Lanzi stigmatized Cesari as not less the corrupter of taste in painting than Marino was in poetry. The defects of drawing and perspective in his work may be seen in his frescoes in the Capitol at Rome, which occupied him at intervals during 40 years. He died in Rome in 1640. His brother Bernardino assisted in many of his works.

CESAROTTI, MELCHIORE (1730–1808), Italian poet, was born on May 15, 1730, at Padua, where he held the chair of rhetoric, and in 1768 the professorship of Greek and Hebrew. Cesarotti is best known as the author of an admirable translation (2 vols., 1763) of Ossian, which raised up many imitators of the Ossianic style. He also produced a number of prose works on aesthetics. He died at Padua on Nov. 3, 1808.

See the complete edition of his works (42 vols., Pisa, 1800–13); F. Barbieri, *Memoirs* (Padua, 1810); L. Alemanni, *Un Filosofo delle lettere* (Turin, 1894).

CESENA (anc. CAESENA), a town and episcopal see of Emilia, Italy province of Forlì, 12m. S.E. by rail from the town of Forlì, on the line between Bologna and Rimini, 144ft. above sea-level. Pop. (1936) 20,043 (town); 61,314 (commune). The town is at the foot of the Apennines, and is crowned by a mediaeval fortress (Rocca). The fine early Renaissance library was built for Domenico Malatesta in 1452 by Matteo Nuti, and its internal arrangements, with the original desks to which the books are still chained, are well preserved. It also contains a picture gallery. There are some fine palaces in the town. On the hill to the south-east the handsome church of S. Maria del Monte, after the style of Bramante, has carved stalls of the 16th century. The ancient Caesena was a station on the Via Aemilia and a fortress in the wars of Theodoric and Narses. In 1357 it was unsuccessfully defended by the wife of Francesco Ordelaffi, lord of Forlì, against the papal troops under Albornoz. In 1377 it was sacked by Cardinal Robert of Geneva (afterwards Clement VII., antipope). It was then held by the Malatesta of Rimini until 1465, when it came under the dominion of the Church. Both Pius VI. (1717) and Pius VII. (1742) were born at Cesena.

CESNOLA, LUIGI PALMA DI (1832–1904), Italian-American soldier and archaeologist, was born at Rivarolo, near Turin, Italy, on July 29, 1832, of an ancient but impoverished family. Educated for a military career, he served with distinction against Austria (1848–49) and in the Crimean war, and going to New York in 1860, founded there a training school for army officers. He fought in the American Civil War as colonel of a New York cavalry regiment, received mention for bravery in several encounters, was wounded and imprisoned, and after the war was brevetted brigadier-general. Renouncing his Italian titles, he received a presidential appointment as U.S. consul to Cyprus (1865–77), where he made extensive excavations of ancient pottery at Larnaca and Salinos, and verified and surveyed the sites of Paphos, Soli and Pali. In 1872 the New York Metropolitan Museum purchased his collection, which became the nucleus for subsequent extensive acquisitions. In 1879 he was appointed director of the museum, a post which he filled until his death, and in which he displayed foresight and energy. The authority of his restorations was questioned in an article in the *New York Herald* (Aug. 1880), but the question, on being referred to a special committee, was decided in his favour. In 1897 he received a Congressional medal of honour for conspicuous military services. He died in New York on Nov. 21, 1904. He is the author of *Cyprus, Its Ancient Cities, Tombs, and Temples* (1877), and of a *Descriptive Atlas of the Cesnola Collection of Cypriote Antiquities* (1884–86). His brother, Alessandro Palma di Cesnola, born in 1839, conducted excavations at Paphos (where he was U.S. vice-consul) and Salamis, on behalf of the British Government. These are described in *Salaminia* (1882). (*See* CYPRUS.)

For the Cesnola controversy, *see* D. D. Cobham's *Attempt at a Bibliography of Cyprus* (4th ed., 1900). (W. B. P.)

CESPEDES (in Ital. CEDASPE), **PABLO DE** (1538–1608), Spanish poet, painter, sculptor and architect, was born at Cordova and educated at Alcalá de Henares, where he studied theology and oriental languages. On leaving the university he went to Rome, where he became the pupil and friend of Federigo Zuccaro, under whose direction he studied particularly the works of Raphael and Michelangelo. In 1560, while he was yet in Rome, proceedings were taken against him by the Inquisition at Valladolid, but they were dropped. He returned to Spain a little before 1577 and received a prebend of the cathedral at Cordova, where he resided till his death. Cristobal de Vera, Juan de Peñalosa and Zambrano were among his pupils. His best picture is a "Last Supper" at Cordova, but there are good examples of his work at Seville and at Madrid. Cespedes was author of several opuscules in prose on subjects connected with his profession. His poem on "The Art of Painting," partly preserved by Pacheco, is esteemed the best didactic verse in Spanish. It contains a glowing eulogy of Michelangelo. The few remaining fragments were first printed by Pacheco in his treatise *Del arte de la pintura*, in 1649.

CÉSPEDES Y MENESES, GONZALO DE (1585?–1638), Spanish novelist, was born at Madrid, and published his celebrated romance, the *Poema trágico del Español Gerardo, y desengaño del amor lascivo* in 1615–17. His treatment of political questions in the *Historia apologética en los sucesos del reyno de Aragón, y su ciudad de Zaragoza, años de 91 y 92* (1622), having led to the confiscation of the book, Céspedes took up his residence at Saragossa and Lisbon. While in exile he issued a collection of short stories entitled *Historias peregrinas y exemplares* (1623), and wrote the first part of his *Historia de Felipe IV.* (1631), a fulsome eulogy which was rewarded by the post of official historiographer to the Spanish king. Céspedes died on Jan. 27, 1638. His novels, though written in an affected style, display considerable imagination and insight into character. The *Poema trágico* was utilized by Fletcher in *The Spanish Curate* and *The Maid of the Mill.*

The *Historias peregrinas* had been reprinted (1906) with a valuable introduction by Sr. Cotarelo y Mori.

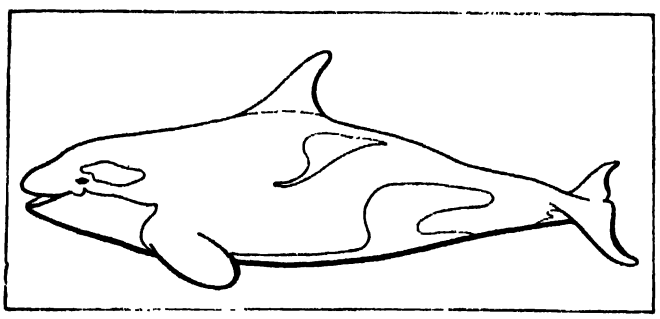
CESS, a term formerly more particularly applied to local taxation, in which sense it still is used in Ireland; otherwise it has been superseded by "rate." In India it is applied, with the qualifying word prefixed, to any taxation, such as "irrigation-cess" and the like, and in Scotland to the land-tax. The word is a shortened form of "assess"; and the spelling is due to a mistaken connection with "census."

CESSIO BONORUM, in Roman law, a voluntary surrender of goods by a debtor to his creditors. It did not amount to a discharge unless the property ceded was sufficient for the purpose, but it secured the debtor from personal arrest. The creditors sold the goods in satisfaction, *pro tanto*, of their claims. The procedure of *cessio bonorum* avoided infamy, and the debtor, though his after-acquired property might be proceeded against, could not be deprived of the bare necessaries of life. The main features of the Roman law of *cessio bonorum* were adopted in Scots law, and also in the French and several other legal systems. In England it exists under the internal regulations of certain commercial bodies, such as the recognized Stock Exchanges. In Scotland the

process of *cessio bonorum* was abolished by the Bankruptcy (Scotland) act, 1913. (*See* further, BANKRUPTCY.)

CESTI, MARC'ANTONIO (1618–1669), Italian musical composer, was born at Florence (or according to some authorities at Arezzo) in 1618. He was a pupil of Carissimi, and is known principally as a composer of operas, notable for the pure and delicate style of their airs, the most celebrated of which were *La Dori* (Venice, 1663) and *Il Pomo d' Oro* (Vienna, 1666–67).

CESTIUS, LUCIUS, surnamed PIUS, Latin rhetorician, was a native of Smyrna, a Greek by birth. According to Jerome, he was teaching Latin at Rome in the year 13 B.C. As an orator in the schools he enjoyed a great reputation. As a public orator, on the other hand, he was a failure. Specimens of his declamations will be found in the works of Seneca the rhetorician.



See Seneca, *Controv.*, ix 3, 12; J. Brzoska, in Pauly-Wissowa's *Realencyklopädie*, iii, 2 (1899) and *Suasoriae*, vii, 13 (for anecdotes).

CESTUI, CESTUY: *see* TRUST AND TRUSTEES.

CETACEA, an order of mammals (from the Gr. κῆτος, a whale), divisible into three suborders: Archaeoceti, exclusively fossil; Mystacoceti, whalebone whales; and Odontoceti, toothed whales, comprising sperm whales, bottle-nosed whales and dolphins. The term "whale" does not indicate a natural division of the order, and it is used here to mean any member of the Cetacea, irrespective of size. The lengths of these animals are mostly between 4 and 100 ft. Their ancestors were probably land mammals, whose structure has been modified in many respects to adapt them for life in the water, from birth to death. Whales are warm-blooded, breathing air by lungs, without scales in their skin, with hands of the five-fingered type, with skeleton, brain, heart and blood vessels mammalian in structure, reproducing like other mammals and nourishing their young with milk; in all these respects differing essentially from fishes, to which they have a merely superficial resemblance. Certain species swim habitually in large schools. A few live entirely in fresh water. The majority are marine, some frequenting the coasts, but others oceanic, rarely approaching land. Many undertake extensive migrations and have a wide distribution. Whales have been known to follow a ship for several consecutive days, and Racovitza has used this as an argument for the view that they do not sleep.

External Form (fig. 1).—Whales swim mainly by the tail, which is produced into two horizontal flukes, not supported by any part of the skeleton, and are thus easily distinguished from fishes, in which the tail is vertical. A dorsal fin, similarly without skeleton, is generally present. The mouth has immovable lips. The fore limbs (flippers) have the form of paddles and are used

FETLN TUTKEN

FIG. 1.—KILLER (GRAMPUS ORCA), THE LARGEST OF THE DOLPHINS

principally for maintaining the balance of the body and for steering. External hind limbs are wanting. The neck is short and rarely distinguishable in the living animal. The nostrils (blowholes) have been shifted to the upper side of the head, at some distance from the tip of the snout or beak (except in the sperm whale). The part in front of the blowhole may resemble a forehead, but it really belongs to the beak. Eyes are well developed, but there are no external ears and the outer opening of the ear is minute. The skin is smooth, hairs being usually absent in the adult, except as occasional vestiges. The vent is at the root of the tail, behind the reproductive opening, on either side of which, in the female, is a groove containing a teat. The umbilicus (navel) is often visible farther forward, especially in young individuals.

Other Distinguishing Characters.—The brain case is short and lofty; the nasal canals pass nearly vertically downward in front of it, and the facial part is prolonged horizontally forward as a rostrum. The auditory bones are highly modified; the tympanics are shell-like and loosely attached to the skull. The neck vertebrae are of the typical mammalian number (seven), short often fusing with one another; the second, if free, has no prominent odontoid process, the structure on which the head turns in other mammals. The lumbar and caudal vertebrae are freely movable, the interlocking processes of their upper arches disappearing from the thorax backward. The ribs are very movable on the vertebrae and sternum (breastbone). The clavicles (collarbones) are wanting. The flippers show no external division into hand, forearm and upper arm and are without definite joints at the elbow and wrist. They contain the typical mammalian bones, but the finger joints (phalanges) are more numerous in some of the digits than in other mammals. Digits are five or four without nails. The pelvis is represented by a small curved bone on each side, embedded in the flesh near the reproductive opening; it does not articulate with the vertebral column, which has no fused sacral vertebrae. In right whales and the sperm whale each half may carry a small bony or cartilaginous vestigial hind limb. The brain is large, its cerebral hemispheres much convoluted. Olfactory organs are almost absent, the nasal passages being functionally continuous with the larynx. The diaphragm is very oblique, and the stomach has several distinct chambers. The main arteries and veins break up into plexuses of vessels known as *retia mirabilia*. The kidneys are lobulated. The male organ is usually completely retracted, thus not interrupting the smooth contour of the body. The testes are within the abdomen, the uterus bicornuate, the placenta diffuse.

Respiration.—A large whale usually rises to breathe every 5 to 10 minutes, but the interval may be at least 45 minutes. The blowholes (fig. 2) are either two longitudinal slits (whalebone whales) or a single crescentic slit (toothed whales). On reaching the surface, the whale exposes and opens its nostrils, which are closed during submergence, and discharges the exhausted air from its lungs. This is done with considerable force, often producing an audible sound, and the animal is said to blow. The moist air projected upward is visible from a long distance, in the case of the larger whales, as a column containing particles of condensed water (the spout) formerly regarded as a fountain of water ejected from the head. Expiration is followed immediately by inspiration, and the whale then sinks horizontally. It repeats these actions several times, rising to the surface on each occasion without exposing much more than the part of its head which carries the blowholes. When it has thus thoroughly changed the air in its lungs, it rises in a different manner. The back is strongly arched and much of it becomes visible. The back fin, if present, appears to be situated on a rotating wheel, rising from behind, reaching the summit of the arched back and descending into the water in front. The whale then leaves the surface and is said to sound. The maximum depth of its dive has been supposed to be at least 100 fathoms. The right whales, humpback and sperm whale (but not the rorquals) usually throw their tails above the surface as they sound; and at other times, like many of the dolphins, they leap completely clear of the water. Differences in these respects, and in the form and direction of the spout, enable whalers to distinguish species.

FIG 2 – BLOWHOLES, FROM ABOVE
A. Whalebone whale
B. Dolphin

The horizontal position of the tail flukes facilitates rising to the surface and returning to the depths, movements of vital importance to the Cetacea. Another effective adaptation to aquatic life is the course taken by the air in passing to the lungs. The larynx and epiglottis form a tube passing through the pharynx into the lower end of the nasal passages (fig. 3). Here it is grasped by the soft palate, and the blowholes thus become continuous with the

windpipe and lungs, the mouth being used solely for feeding—as in recently born marsupials, but not as in other adult mammals, which can breathe through either the nose or the mouth.

Prolonged submergence involves other demands on the respiratory organs. The thoracic cavity of the Cetacea is unusually extensible, and thus provides for a corresponding expansion of the lungs, depending on the loose attachments of the ribs and the

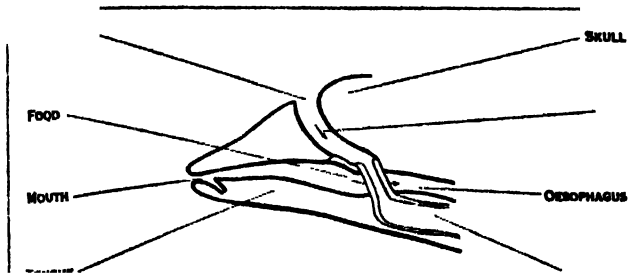

FIG. 3. MEDIAN SECTION OF THE HEAD OF A PORPOISE, TO SHOW THE COURSE TAKEN BY AIR AND BY THE FOOD

considerable projection of the oblique diaphragm into the cavity of the contracted thorax. Whales have a larger amount of blood, in proportion to their size, than other mammals, and this involves an increased capacity for carrying oxygen to the tissues by means of haemoglobin, the red colouring matter. The very deep red colour of the muscles seems to imply that these structures also hold a specially large quantity of oxygen. The characteristic rete mirabilia are further adaptations. In the common porpoise, for instance, the upper and lateral parts of the thorax are covered by an elaborate arterial rete mirabile, lying just outside its lining membrane. Branches of this plexus extend upwards into the neural canal of the vertebral column, an arrangement which ensures an adequate supply of oxygen to the spinal cord and brain. Although physiological evidence cannot be quoted, the retia mirabilia probably act as reservoirs, the arterial portions containing a large supply of oxygen, the amount of which may largely influence the duration of submergence. The venous portions probably hold exhausted blood, which would otherwise circulate too freely. The principal danger to which a diver is exposed is the liberation of gas-bubbles into his blood, due to diminishing water-pressure, if the ascent to the surface is too rapid. The retia may perhaps have the function of retaining bubbles and of preventing their access to the general circulation.

Hair.—Whales maintain a constant high temperature, not very different from that of man. A hairy coat has been discarded, as a means of avoiding the loss of heat, in favour of blubber; but a few vestigial hairs may occur—an unmistakable sign of the origin of Cetacea from land mammals. In *Inia* numerous scattered hairs occur on the beak. Whalebone whales have hairs, in *Rhachianectes* up to 40 mm. long, on parts of the head and lower jaw; and in dolphins a few long hairs are found on the beak, before birth.

Skin and Colour.—The outer, horny layer of the epidermis is thin and readily separates from the body after death. The deeper layer is nearly always pigmented in certain parts, which then appear black, or varying shades of gray, brown or blue. The commonest type of colouration is dark above and white below, the relative extent of these regions varying with the species, the white area sometimes increasing with age. Many dolphins have a black streak extending from the eye to the flipper, perhaps representing the lower limit of the ancestral dark region. Some whales are completely black or white. In certain cases the normal white is replaced by a bright yellow colour. A. G. Bennett found that in Antarctic rorquals this is due to an external film composed of an enormous number of diatoms. These unicellular algae were found all over the skin, but were not conspicuous on the dark parts. In the common porpoise and its allies the skin of the edge of the dorsal fin or flippers bears a series of small, horny tubercles, which have been considered by some authors to indicate an affinity to Edentate mammals, a conclusion not universally accepted. The deeper part of the skin (dermis) is usually inconspicuous, but is better developed in the Delphinapterinae. The white whale, belonging to this subfamily, has a thick epidermis and a rather thinner dermis, and its skin has been used commercially as "porpoise leather."

Blubber.—This characteristic part of a cetacean is formed of tough fibrous tissue enclosing an enormous amount of oil. It invests every part of the whale, but is thicker in certain regions, for instance near the dorsal fin. In the sperm whale the maximum thickness is as much as 14 in., and in the Greenland whale 20 inches. In the latter, according to Scoresby, 4 tuns of blubber, by volume, yield 3 tuns of oil. In a whale of 70 tons the blubber weighs about 30 tons, and 2 tuns of oil may be extracted from each of the gigantic lower lips. The blubber of the rorquals now hunted is thinner, and in the smaller dolphins it does not much exceed one inch. Although specially important in retaining heat, the insulating properties of this layer probably afford protection against an excess of warmth in tropical waters. Blubber is little developed in newly born whales, and perhaps for this reason the parent resorts to warmer water to give birth to her young. It varies in condition at different times, a whale being often lean on its first arrival in polar seas, where the blubber improves in quality owing to the large amount of food found in those waters. The stomachs of whales captured in temperate latitudes are sometimes empty, and blubber is probably a reserve material which can be drawn on when food is scarce. It may further help materially to prevent the crushing of the tissues, during a deep dive, by the enormous pressure of the superjacent water.

Food.—Dolphins typically eat fishes, to which diet they are adapted by their teeth, generally numerous and uniformly conical; but cuttlefish also may be eaten. The stomach of a species of *Sotalia* has been found to contain vegetable matter. The Killer is exceptional in eating marine mammals and birds, in addition to fishes. The sperm whale and the bottle-nosed whales (Ziphiidae) are mainly dependent on cuttlefish, some of which must be obtained at considerable depths; but these also take occasional fishes. A diet of cuttlefish is often associated with a reduction of the number of teeth, in certain dolphins, the sperm whale and the Ziphiidae.

Whalebone.—The whalebone whales feed exclusively on plankton (*q.v.*), including fishes. They obtain food by means of a whalebone sieve, and the adequacy of the method may be estimated by the fact that two tons of plankton have been taken from the stomach of a blue whale. Plankton is specially abundant in the cold waters of both polar regions, and whales visit them to profit by this plenty.

Whalebone or baleen is derived from the skin lining the mouth and has nothing to do with true bone. The sieve is composed of

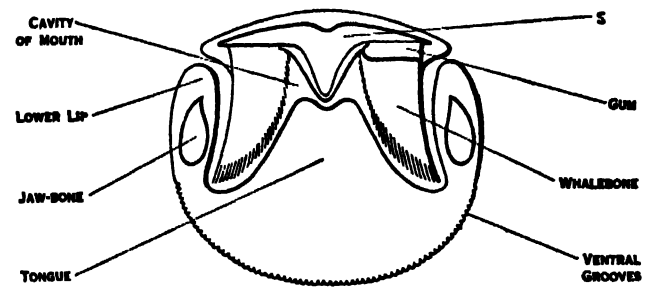

FIG. 4.—TRANSVERSE SECTION OF A RORQUAL'S HEAD TO SHOW WHALEBONE

two sides, each running longitudinally along the entire length of the outermost part of the palate, and being continuous with its fellow at the front of the beak. A side consists of as many as 300–400 transversely placed, flexible, and horny blades, embedded at their base in a substance known as the gum, and with a short interval between each two. The blades are longest and widest at the middle of the series and progressively smaller towards both ends, where they become very short. Seen from the front or back, an isolated blade appears roughly triangular (fig. 4), the shortest side embedded in the gum, the outer border straight, and the inner

border slightly convex. On the inner aspect of each principal blade is a transverse row of a few very short blades; and all the blades are produced into long hairlike structures, composed of the same substance as the whalebone itself. Owing to the presence of these hairs, the sieve, seen from its inner side, resembles a doormat or the fleece of a sheep. Between the two sieves lies the tongue, which is of immense size, in contrast with the much smaller tongue of the toothed whales.

The two halves of the lower jaw are greatly arched outwards, the mouth being thus enormous. The blades are bent backwards by the closure of the mouth, recovering a vertical position, by their own elasticity, as it opens. The great lower lip overlaps the outer edges of the blades, and the water must thus escape from the mouth through the chinks between these structures. The whale feeds, after sounding, by swimming through a shoal of plankton with its mouth open. Water enters at the front end; and, before it leaves, the food has been strained off by the hairy fringes of the baleen plates. The mouth is then closed, the tongue having no doubt helped to force out the water, while licking the food off the sieve. The characters of the baleen afford one of the most convenient ways of distinguishing species of whalebone whales. The blades are longest in the Greenland whale, where they may reach the astonishing length of 15 feet.

Sense Organs.—The olfactory organs are greatly reduced, and it is doubtful whether whales have the sense of smell. The nasal passages, however, are of vital importance, since they serve as the sole method of admitting air to the lungs. The eyes are small, with arrangements for withstanding water pressure. W. Scoresby stated that vision is acute in the Greenland whale, which is dull of hearing in the air, but is readily alarmed by even a slight splashing in the water. The external auditory passage is narrow and opens by a minute hole on the head, not far behind the eye. In whalebone whales it is blocked by a large mass of wax, several inches in length, and it cannot be of much service in hearing. It is believed that vibrations in the water reach the ear through sacs given off by the Eustachian tubes or through the bones and other tissues of the head. The tympanic bones are dense and conchlike, well developed and attached to the periotic by two slender pedicles. There can be little doubt that the auditory organs are of real importance.

Breeding.—The Cetacea are in all respects typically mammalian in their reproduction. The young is nourished in the uterus by a placenta, and is not born until it has attained a form essentially that of the adult, sometimes exceeding one-third the length of the mother. In the common porpoise (5½ ft.) the newly born young is about 2 ft. long, and in the largest whalebone whales at least 20 feet. A single young is typically produced, but twins occur and 7 foetuses have been found in a blue whale. The period of gestation is probably something less than a year, but whalebone whales are commonly believed not to produce young more often than once in two years. In certain species birth appears to take place at a more or less definite season, as in the common porpoise, principally in the late spring or early summer. Among whalebone whales there is some reason to believe that the frequencies of births, and therefore of pairings, in the several months can be represented by a regular curve showing a distinct maximum at a definite period in the year; although either of these events may occur in any month. This view has been supported by finding a close agreement between the breeding curves of northern and southern races of the same species, with the significant difference that the maxima are about six months apart, corresponding with the difference in seasons between the two hemispheres. Tropical species, such as the sperm whale, perhaps have no definite breeding period.

Migrations.—The principal movements of many whales are largely connected with the two functions of feeding and reproduction. The humpback, for instance, appears in large numbers in sub-antarctic waters in the spring (October) and remains there till the summer. As the season advances it becomes less numerous, but it is found off the south and west African coasts at the time that would be expected on the assumption that it is moving northwards. At the height of the southern winter it is found even as far north as the equator, and it travels southwards again as the spring returns. It is probable that this species, like others, seeks warmer water in which to bring forth its young and that pairing takes place at about the same time. Its journey to the far south is for the purpose of feeding.

Growth and Age.—Little can be said of the duration of life in whales; and statements that large individuals must be of great age may be dismissed as unproven. Young whales may be found accompanying their mothers, and probably subsisting on milk, up to a length of 40 or 50 ft., appearing to imply a growth to that size in the first year. The females of the same species may be pregnant at about 60 ft.; and it has been suggested that a whale reaches the reproductive age very early in life. The condition of the skeleton gives information as to the relative age of whales. Many of the bones of mammals grow at their ends by two bony epiphyses, which are at first separable and in the vertebrae are conspicuous discs of bone. The adult condition, at which growth stops, is reached when the epiphyses have completely fused with the main bones. It was pointed out by Sir William Flower that fusion begins at the two ends of the vertebral column; the cervical and caudal vertebrae commencing the process, which gradually extends from both ends towards the middle. This obviously gives some information as to the relative age of adolescent individuals, but it leaves untouched the question of the duration of life.

Species Hunted.—The whaling industry (*see* WHALE FISHERIES) has been mainly based on about nine species, of which all but the sperm whale are whalebone whales. The Basques hunted the Atlantic right whale (*Eubalaena glacialis*) at an early date, and the industry was specially flourishing in the 12th and 13th centuries. The arctic fishery began about 1611 and was based on the Greenland whale (*Balaena mysticetus*). The hunting of the sperm whale (*Physeter catodon*) began about a century later; and the southern right whale (*Eubalaena australis*) was captured in large numbers by some of the vessels subsequently engaged in this industry. The Pacific gray whale (*Rhachianectes glaucus*) was taken in considerable numbers on the coast of California before the middle of the 19th century. Modern whaling depends mainly on two species of rorqual, the great blue whale (*Sibbaldus musculus*) and the fin whale (*Balaenoptera physalus*) though the sei whale (*B. borealis*) is not unimportant in certain localities. The humpback (*Megaptera nodosa*) has at times been the most important constituent of the catch of modern whalers, who in one or two localities take a few specimens of Bryde's whale (*Balaenoptera brydei*). The following, of less importance commercially than the great whales, have also been systematically captured by whalers or fishermen at various times:—the narwhal (*Monodon monoceros*), the white whale (*Delphinapterus leucas*), the pilot whale (*Globicephala ventricosa*), the bottle-nosed whale (*Hyperoodon rostratus*), the common porpoise (*Phocoena phocoena*), and others of the smaller dolphins.

History gives a melancholy record of the results of intensive whaling. The Atlantic right whale is no longer to be found on the Biscay coast, and, though it made some recovery during the 19th century, it was believed at one time to have become extinct. The southern right whale, once extremely common on the coasts of South Africa and Kerguelen, and in other localities, is occasionally represented in whaling returns by a very few specimens. The Greenland whale disappeared successively from the bays of Spitsbergen, the Greenland sea, Davis straits and the region of Bering straits. There is no indication of the reappearance of these animals off Spitsbergen or Jan Mayen, where they were formerly present "in immense numbers"; and, though a few probably linger in some of the old localities, the Greenland trade is dead. The Pacific gray whale was nearly exterminated off the coast of California, and was thought to be extinct. It has recently reappeared in small numbers, and a few are being taken by the Japanese in their own waters. The capture of humpbacks has seriously declined. In 1844 the United States alone had 315 vessels employed in the chase of the sperm whale, but one fishing ground after another had to be abandoned. Sperm whales are still taken at whaling stations, off the coasts of Natal and

the British Isles and in the Straits of Gibraltar, but the large fleets formerly engaged in the chase of these animals have ceased to exist. Of the important species, the blue whale, the fin whale, the humpback, the sei whale and the sperm whale alone survive in considerable numbers; and the disappearance of the first two would involve the extinction of the greater part of the industry.

The invention of an improved harpoon gun in 1865 gave a new impetus to whaling, and this has culminated in the extraordinary success of operations in the dependencies of the Falkland Islands and Ross sea. The reintroduction of pelagic whaling, by methods far more efficient than those formerly practised, has resulted in new dangers to the whales.

The facts are ominous, and history is likely to repeat itself unless adequate steps can be taken in time. Experience has shown that whales do not readily come back to an old locality, even when they have been free from pursuit for many years. The number of whales recently taken in sub-antarctic waters has several times exceeded 30,000 in a single season, and in 1937–38 it was more than 46,000. History gives no justification for the belief that whaling can continue indefinitely at this rate, and the necessity of controlling the industry is urgent.

Commercial Products.—Whalebone, the most valuable product of the Greenland whale, was at one time worth £2,000 a ton. That of the rorquals is shorter and of inferior quality. Oil is produced by all Cetacea, but the sperm oil of the sperm whale and Ziphioids differs in constitution from the train oil or whale oil of other whales. Spermaceti and ambergris are products of the sperm whale. Guano and other materials are obtained by treating the dried flesh and bones of large whales. Meat of good quality is available from nearly all Cetacea. The flesh of dolphins was formerly esteemed a delicacy; and it had the advantage, in Roman Catholic countries, of being considered fish which could be eaten on fast days. The common porpoise was formerly hunted on a large scale for its meat. Ivory is obtained from the tusk of the narwhal and from the teeth of the sperm whale. Leather can be prepared from the skin of the white whale.

CLASSIFICATION

Suborder 1.—ARCHAEOCETI. The *Basilosauridae, Dorudontidae* and *Protocetidae* of the Eocene and Oligocene, constituting this group, are believed to have been derived from the Creodonta, the primitive fossil members of the Carnivora; but Gregory thinks that they may have descended from Insectivora of the type represented by *Pantolestes*. Their skull characters are intermediate between those of their supposed ancestors and those of recent Cetacea in the position of the nostrils, the relations of the maxillae and the dentition, which consists of 3 incisors, 1 canine, 4 premolars, and 3–2 molars on either side of each jaw. The first 4 or 5 teeth are conical and single-rooted, and the other teeth are double-rooted, with serrated crowns. A milk dentition is found.

The recent Cetacea have no milk teeth, and there is no differentiation into incisors, canines and molars. The *Squalodontidae* (Oligocene to Pliocene), included in the Odontoceti, are believed to have descended from the Archaeocetes and to have given rise to some at least of the recent toothed whales. The origin of the Mystacoceti is uncertain.

Suborder 2.—MYSTACOCETI, whalebone whales. Whalebone present; teeth wanting in the adult, numerous and vestigial in the embryo; lower jaw large, its halves curved outwards (fig. 5, B) and loosely united in front; blowholes two longitudinal slits (fig. 2, A); skull symmetrical, the nasal bones relatively well developed, maxillae not covering the orbital plates of the frontals; first pair of ribs alone joining the sternum, which consists of one piece. The females are slightly larger than the males.

Family 1.—*Rhachianectidae*, with *Rhachianectes glaucus*, Pacific gray whale (fig. L, p. 170; 45 ft.). Head small, less than one-quarter the total length; dorsal fin wanting; flippers 4-fingered. R. C. Andrews considers *Rhachianectes* the most primitive of the Mystacoceti, in view of the occurrence of long hairs scattered over the entire head and lower jaw, the short and relatively few baleen blades, the free neck vertebrae, the large pelvis, and other characters. The lower side of the throat region has two or three grooves. *Rhachianectes* prefers shallow water, swimming even in the surf and occurs in the North Pacific, from California northwards to the Arctic ocean and off Japan and Korea.

Family 2.—*Balaenidae*. Skull much arched; baleen long and narrow; ventral grooves wanting; neck vertebrae fused.

Neobalaena marginata, pygmy whale (20 ft.), is doubtfully placed in this family. It differs from the right whales in its small head, about one-fifth the total length, in its less arched rostrum, in having a dorsal fin and in its 4-fingered flippers. It is known from New Zealand and Australia.

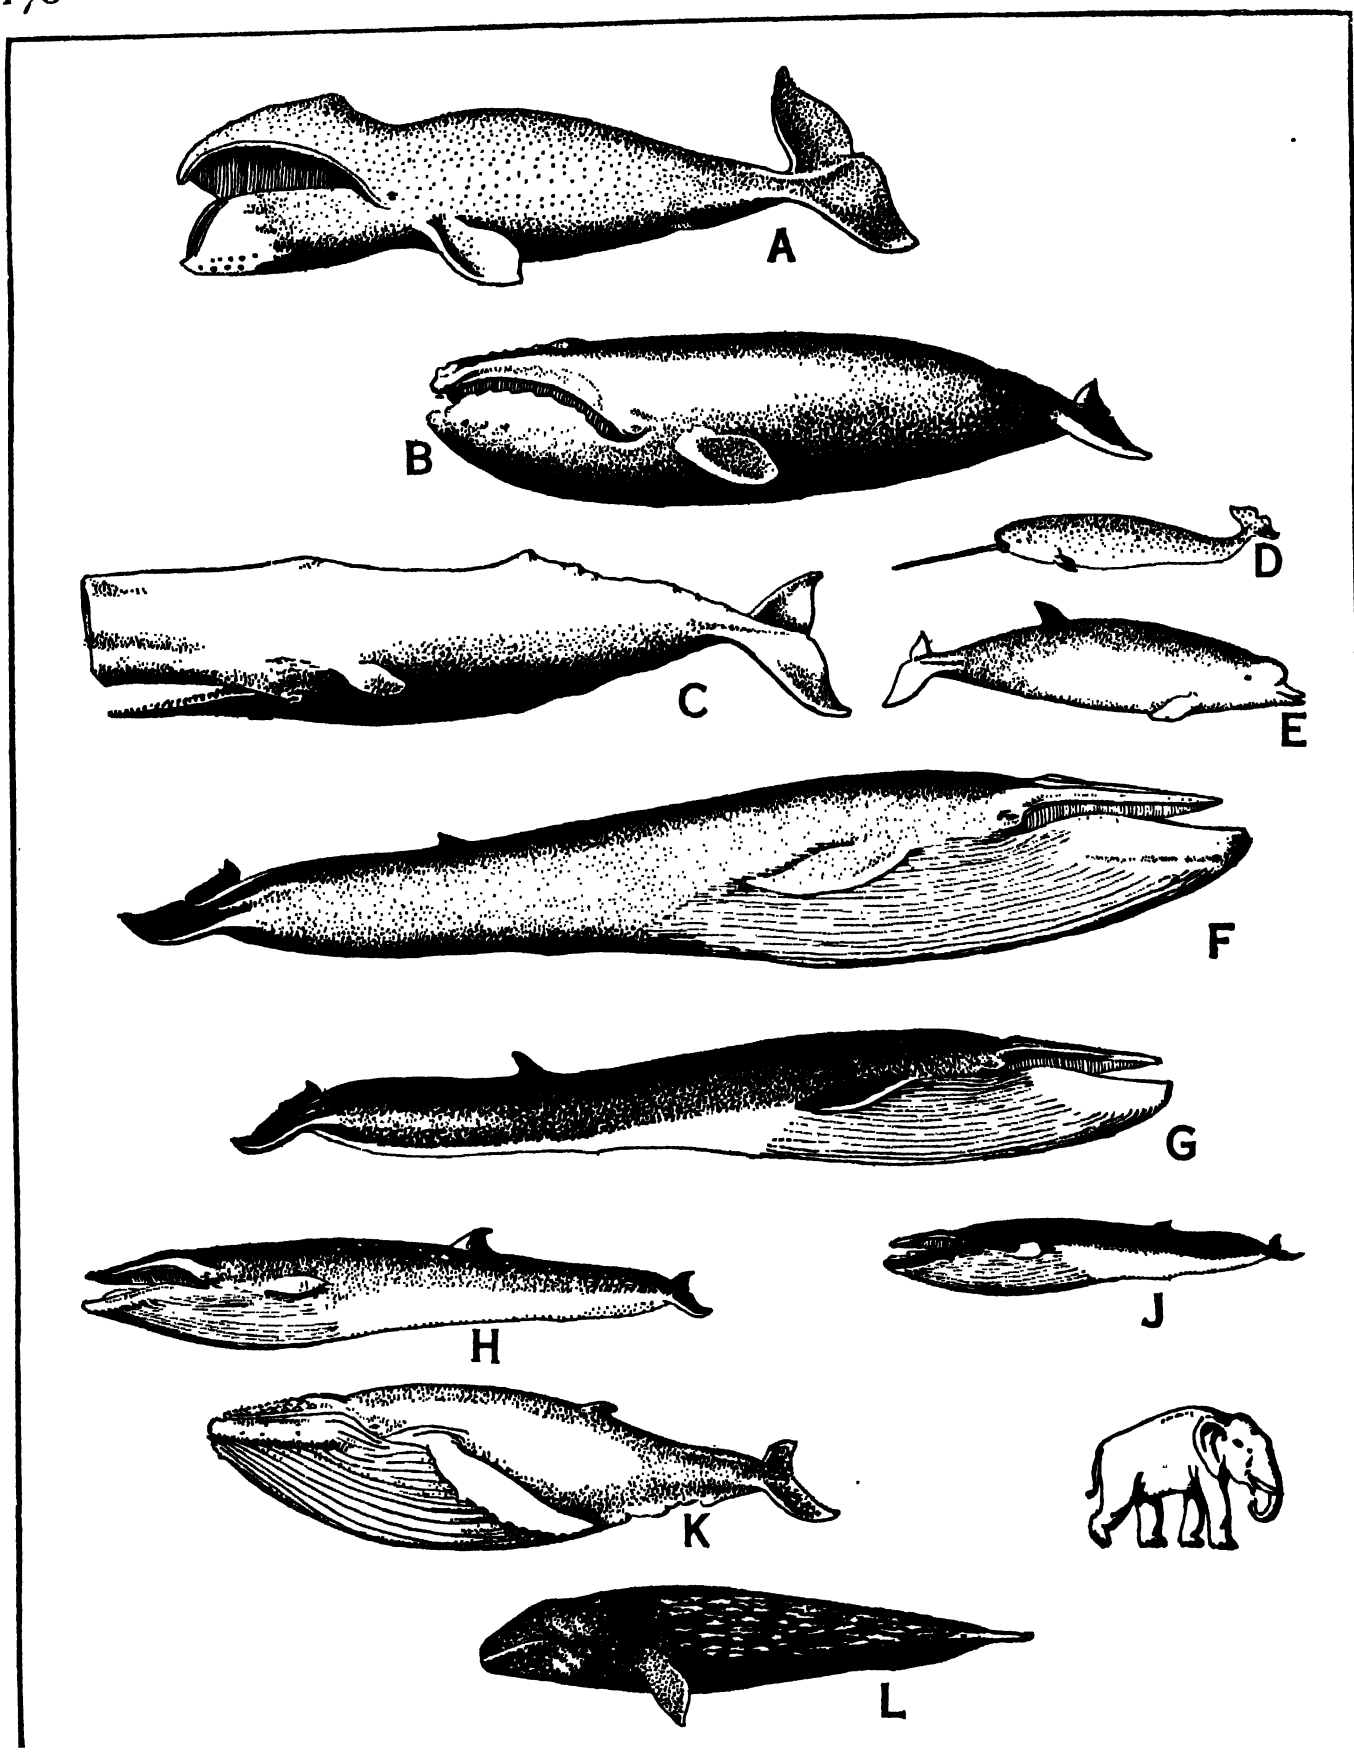
Balaena and *Eubalaena*, right whales. Dorsal fin wanting; flippers broad, with 5 fingers; head one-quarter to one-third the total length.

Balaena mysticetus, Greenland whale (fig. A, p. 170; 60 ft.). Head enormous, one-third the total length; rostrum greatly arched, providing room for exceptionally long baleen, up to 15 feet. Arctic, circumpolar, and formerly abundant off Spitsbergen, both sides of Greenland and the North Pacific to Beaufort sea, but reduced by whaling to the verge of extinction.

Eubalaena glacialis, Atlantic right whale or Biscay whale (fig. B, p. 170), about the same size, but differing from *B. mysticetus* in its less arched head, its shorter baleen (up to 9 ft.) and the shape of its lower lip. It was formerly common in the Bay of Biscay and it has been recorded from the Mediterranean. It has been hunted, in recent years, off Iceland, Norway and the British Isles. It visits the eastern United States, its northern range in the Atlantic coinciding nearly with the southern limit of the Greenland whale; but, like other right whales, it avoids the tropics.

Eubalaena australis, southern right whale. Resembling *E. glacialis*, but found off Australia, Kerguelen and other parts of the southern sea, where 193,522 were killed by American whalers in 1804–17. A few are still taken off South Georgia, the South Shetlands and the African coasts. The *Eubalaena*, hunted in Japan, may be a distinct species.

Family 3.—*Balaenopteridae*, rorquals and humpback. Rostrum less arched than in Balaenidae, baleen blades shorter and broader; dorsal fin present; skin covering the throat with numerous, conspicuous, longitudinal grooves; flippers narrow; neck vertebrae free. At least 90% of the whales now hunted belong to this family.



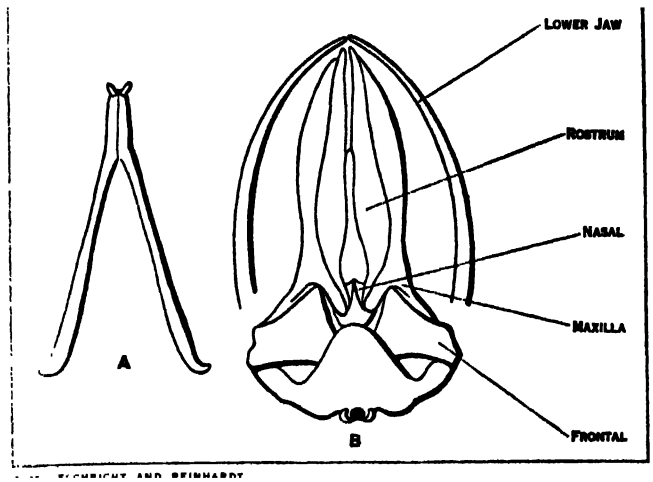
Balaenoptera and *Sibbaldus*, rorquals. Body relatively slender; dorsal fin well marked; flippers small, narrow and pointed.

Sibbaldus musculus, blue whale or Sibbald's rorqual (fig. F. p. 170; at least 100 ft.) is the largest of all animals and the most important in the estimation of modern whalers. Colour nearly uniformly bluish-gray above and below, including both surfaces of the tail-flukes; baleen jet black, with black fringes. Cosmopolitan, on the assumption that (as in others of the family) the northern and southern races belong to the same species, from polar to temperate seas, occasionally reaching the equator. Food, small Crustacea (Euphausians, etc.).

Balaenoptera physalus, fin whale or razorback (fig. G, p. 170; up to at least 80 ft., in the south). Dark above and pure white below, including the lower surface of the tail-flukes. Baleen with alternate, vertical stripes of slate colour and yellow or white, the fringes similarly light in colour, the anterior 3 or 4 ft. of the right series nearly always completely white; lower jaw white on the right side, dark on the left, but the asymmetry of colour of baleen and skin may be reversed. Food, small Crustacea and fishes. This whale is captured in large numbers at most of the whaling stations. Its distribution is as wide as that of the blue whale, but it is rarely found in the tropics. It is common on both sides of the Atlantic, and it enters the Mediterranean. A few are stranded annually on the British coasts.

B. borealis, sei whale or Rudolphi's rorqual (fig. H, p. 170; 52 ft.). White and dark parts not so sharply delimited as in the fin whale; lower surface of tail-flukes bluish-gray; baleen black, its fringes white, silky and curling. Temperate parts of all the oceans, not wandering so near the poles as the two preceding species. Food, Crustacea, less often fishes.

B. brydei, Bryde's whale. Nearly as large as the sei whale, from which it differs in having straight hairs on its baleen blades, and



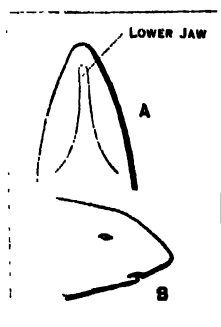
FROM (B) ALLEN, "WHALEBONE WHALES OF NEW ENGLAND." (C) SCAMMON, "MARINE MAMMALS OF N.W. AMERICA," (E) "NATUURKUNDIGE VERHANDELINGEN," (F, G, J, K) "CHRISTIANIA VIDENSKAPSSELSKAPS FORHANDLINGEN." (H, L) ANDREWS, "MEMOIRS OF THE AMERICAN MUSEUM OF NATURAL HISTORY"

VARIOUS TYPES OF WHALES

A, Greenland whale (after Scoresby). B, Atlantic right whale. C, sperm whale. D, narwhal (after Scoresby). E, bottle-nosed whale (after Vrolik). F, blue whale (after Sars). G, fin whale (after Sars). H, sei whale. J, lesser rorqual (after Sars). K, humpback whale (after Sars). L, Pacific grey whale (African Elephant, "Jumbo," 11 feet high, reproduced to same scale)

in its food, which consists principally of fishes. South and West Africa, apparently reaching the West Indies.

B. acutorostrata, lesser rorqual (fig. J, p. 170; 33 ft.). Coloration as in the fin whale (without asymmetry of colour); a conspicuous white area on the outer side of the flipper. Baleen and its fringes all white or yellowish. Food, largely fishes, but also Crustacea. Temperate and polar latitudes of both hemispheres, including the British and both North American coasts, but not hunted.



AFTER ESCHRICHT AND REINHARDT

FIG. 5.—A, LOWER JAW OF TOOTHED WHALE (ZIPHIUS, MALE); B, SKULL OF WHALEBONE WHALE (MEGAPTERA) FROM ABOVE

Megaptera nodosa, humpback (fig. K, p. 170; 52 ft.). Body thick, dorsal fin evanescent; flippers enormously long, nearly one-third the total length. Colour variable, sometimes nearly all black, more with varying amounts of white in other individuals; flippers sometimes pure white; baleen and its fringes black. Food, fishes and Crustacea. Cosmopolitan, from the Arctic to the Antarctic ocean, and more frequenting warm water than the rorquals. The humpback was almost the only species hunted at the commencement of the great antarctic whaling enterprise, beginning 1905, and was almost equally important on the African coasts. The numbers frequenting the whaling localities have greatly diminished.

Suborder 3.—ODONTOCETI, toothed whales. Teeth present throughout life; whalebone wanting; lower jaw more or less triangular (fig. 5, A), the front part often narrow, the two halves firmly united; blowhole single (fig. 2, B); skull asymmetrical, nasals reduced, maxillae covering the orbital plates of the frontals; several pairs of ribs joining the sternum, which consists, in the young at least, of several pieces.

AFTER ESCHRICHT AND REINHARDT

FIG. 6.—WHALE HEADS A, HEAD OF A SPERM WHALE FROM BELOW; B, HEAD OF A KOGIA WHALE FROM THE SIDE

Family 1.—*Physeteridae*, sperm whales. Teeth numerous in lower jaw, vestigial or absent in upper jaw in recent forms.

Physeter catodon, sperm whale (fig. C, p. 170; 63 ft.). Size gigantic; head immense, about one-third the total length; snout enormous, truncated, extended beyond the narrow, ventrally situated mouth (fig. 6, A); lower teeth 20–26 on each side, of great size, up to 4 lb. in weight, conical; about 8 pairs of smaller, often malformed, upper teeth; left nasal passage alone developed, the single blowhole curved, on the upper, left side of the snout, near its front end; dorsal fin reduced to a low hump, continued as a ridge towards the tail; colour black or brown all over, sometimes marked with white, especially in aged individuals. Male up to 63 ft., female not often exceeding 35 feet. The sperm whale occurs in all tropical waters, but stragglers, nearly always old males, reach both polar seas. It is polygamous, a school of females being accompanied by one or two large males. The sperm oil produced by this species is everywhere mixed with spermaceti, most of which is obtained from a receptacle, the case, occupying much of the snout, to the right of the single nasal passage, and capable of containing nearly 500 gal. of mixed oil and spermaceti. The sperm whale dives to a great depth, in pursuit of cuttlefish, its main food, though it also eats fishes. The case is supposed, by its buoyancy, to support the gigantic skull and to facilitate a rapid return to the surface. Ambergris is a morbid concretion of the intestine, commanding a high price.

Kogia, lesser sperm whale (about 10 ft.) resembles *Physeter* in general characters, except for the blowhole, which is located on top of the head, the single nasal passage, and the presence of a spermaceti organ; but the head (fig. 6, B) is relatively much smaller. Lower teeth, about 12 on each side, long, delicate, and curved; upper teeth wanting. Indian ocean and coasts of Australia, and recorded from eastern North America, Brittany and Holland.

Family 2.—*Ziphiidae*, beaked whales. Allied to the *Physeteridae* and producing sperm oil, but teeth much more reduced. A pair of longitudinal grooves in the throat region (fig. 9, A–C). Dorsal fin behind the middle of the body; tail (fig. 7, A) not notched at the junction of the flukes, flippers small; functional teeth (fig. 8, A, B) 1–2 pairs in the lower jaw, generally below the gum in females; minute vestiges of teeth may occur in either jaw. Food, cuttlefish. The rostrum becomes consolidated into a hard, bony mass in *Ziphius* and *Mesoplodon*, and these fragments are found in British late Tertiary deposits.

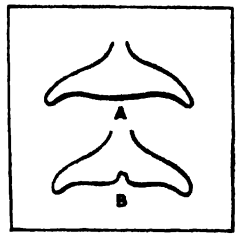


FIG. 7.—TAILS
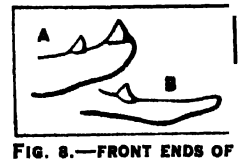
A. Tail of Ziphioid
B. Tail of dolphin

Berardius has 2 pairs of large teeth at the front end of the lower jaw (fig. 8, A). *B. bairdi* (40 ft.), North Pacific, is the largest Ziphioid. *B. arnuxi*, New Zealand, Argentina, not uncommon in antarctic waters.

Ziphius cavirostris, Cuvier's whale (26 ft.) has one pair of teeth at the tip of the lower jaw, much more massive in males (fig. 5, A) than in females, in which they remain beneath the gum. Cosmopolitan, and not uncommon at certain times along the British coasts.

Hyperoodon rostratus, bottle-nosed whale (fig. E, p. 170; male, 31 ft.; female, 25 ft.). Teeth small, one pair (occasionally two pairs) at the tip of the lower jaw, alike in both sexes, remaining concealed till a late period, but then piercing the gum, at least in old males. Distinguished from *Ziphius* by a large bony crest on the upper side of each maxilla. With increasing age these crests become immense in the male, producing a notable alteration in the head, the forehead (fig. 9, B) becoming enormous and truncated. Common in the North Atlantic, where it has been extensively hunted to the north of Scotland; and frequently stranded on the British coasts, though rare in the eastern United States. *H. planifrons*, Australia, New Zealand and Argentina.



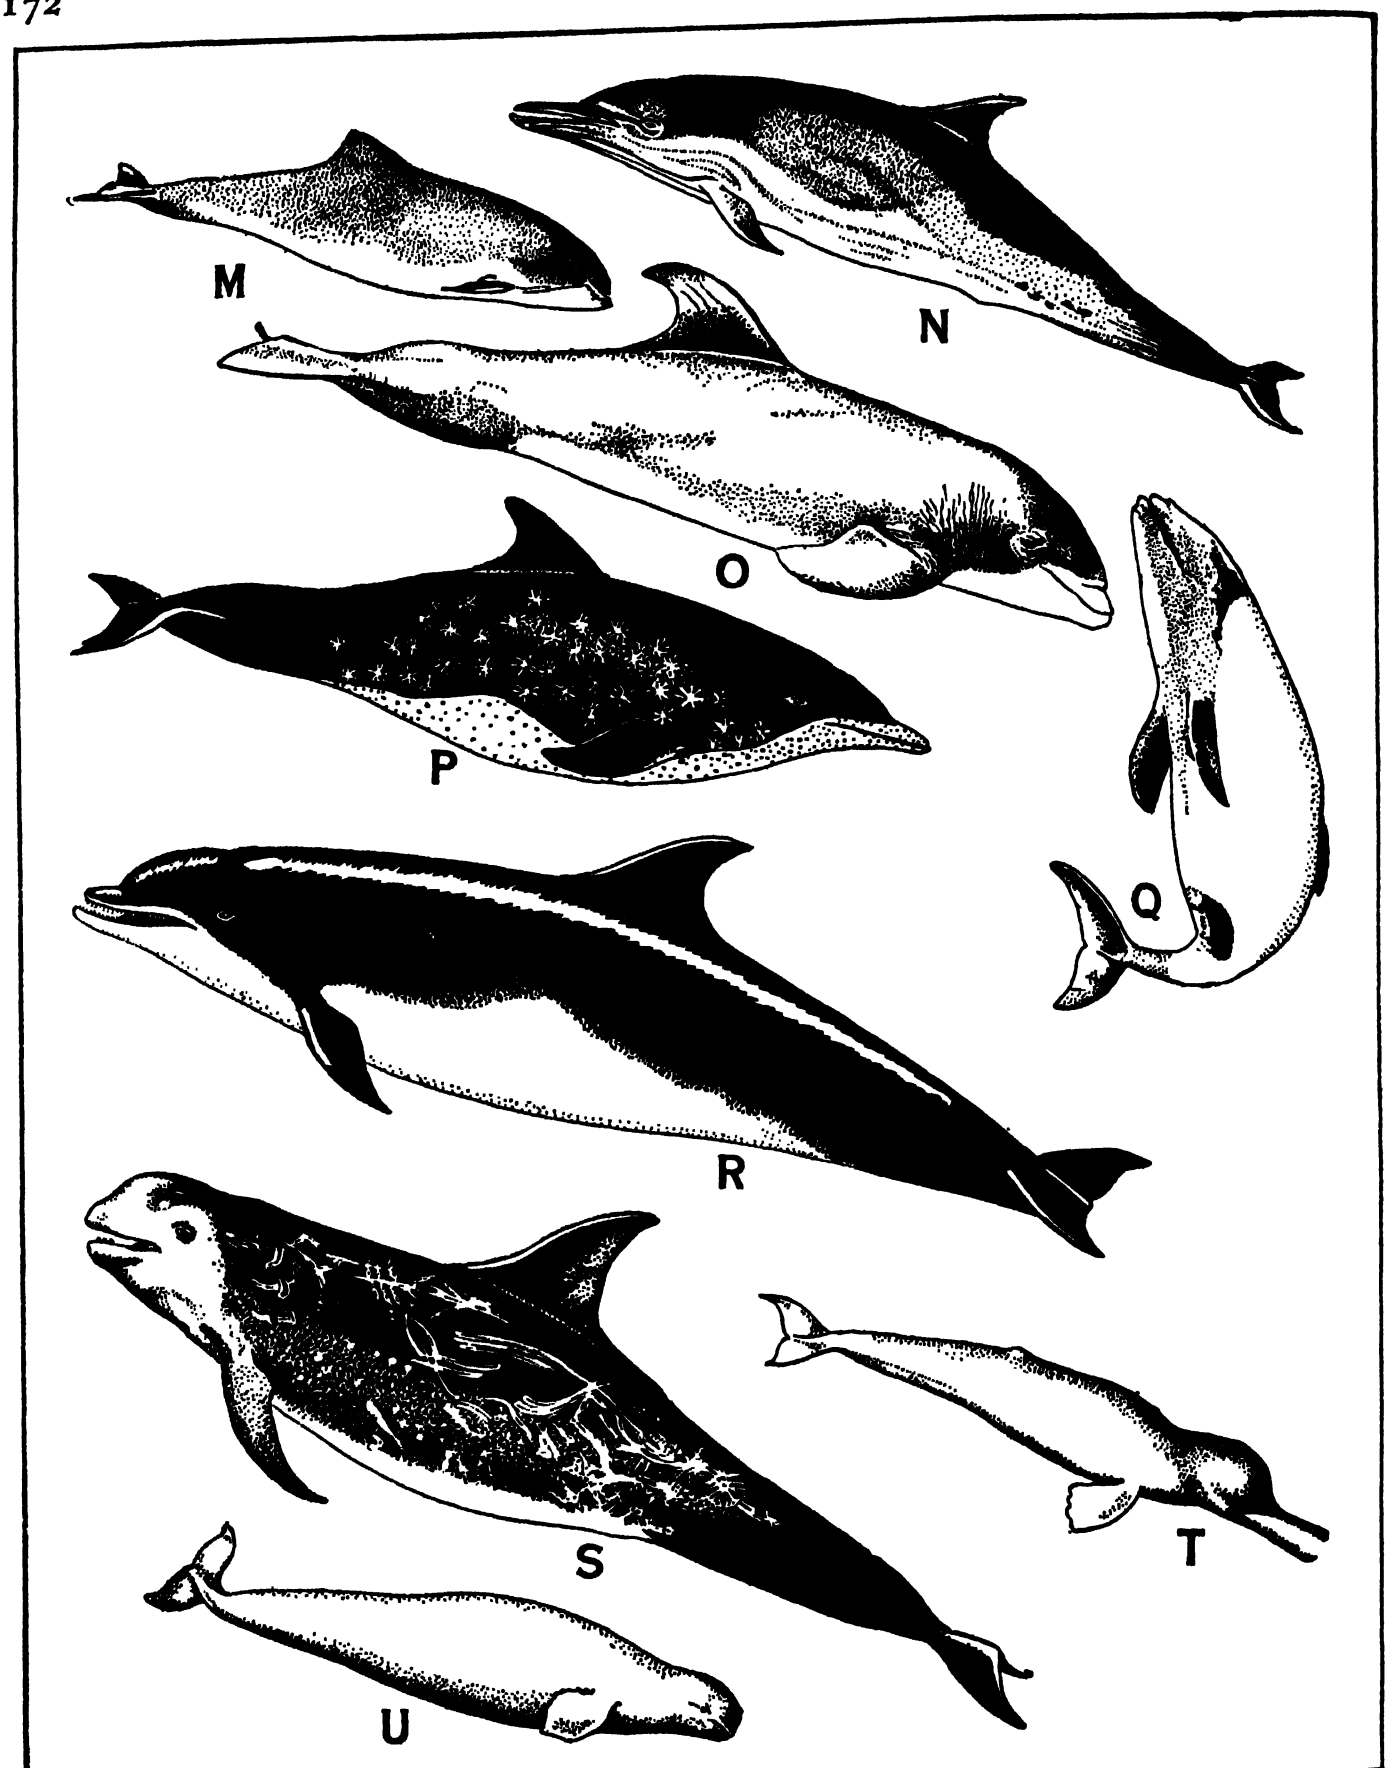


FIG. 8.—FRONT ENDS OF LOWER JAWS
A. Berardius
B. Mesoplodon bidens

Mesoplodon (fig. 9, C). Teeth, one pair (fig. 8, B), smaller in females and usually remaining beneath the gum, typically near the angle of the mouth, but in three species at the tip of the jaw. Of these, *M. mirus* has been stranded on the Irish coast; and *M. pacificus*, described in 1926 from a Queensland skull, appears to be about 25 ft. long, and would therefore be the largest *Mesoplodon*. *M. bidens*, Sowerby's whale (15 ft.), has its teeth in the typical position (fig. 8, B). Up to 1914 nearly half the records were British strandings, the others being from the Baltic to the eastern United States. *M. layardi*, of South Africa, Australia and New Zealand, has an extraordinary modification of its teeth, which curve over the beak, nearly meeting and preventing the mouth being opened to more than a small extent. *Mesoplodon* is oceanic, like other Ziphioids; but its species (about ten) appear to have a relatively restricted distribution.

Family 3.—*Platanistidae*. Inhabiting rivers or estuaries. Neck vertebrae larger than usual, not fused; pterygoid bones completely covering palatine bones on ventral aspect of skull; outer borders of maxillaries prolonged into incurved fanlike structures that largely roof over the facial depression; beak slender; flippers

BY COURTESY OF (M, O) THE TRUSTEES OF THE BRITISH MUSEUM; (N, Q) FROM "TRANSACTIONS," 1880 (ZOOLOGICAL SOCIETY OF LONDON); (P) LUTKEN, "VIDENSK SELSK. SKRIFTER" (DET 'ATTENDE' (H. ASCHEHOUG & CO., OSLO)

COMMON PORPOISE, WHITE WHALE AND TYPES OF DOLPHINS

M, Common Porpoise (after Harmer). N, Common Dolphin (after Flower). O, White-beaked Dolphin (after Harmer). P. Steno rostratus. Q, Commerson's Dolphin (after Harmer). R, Bottle-nosed Dolphin. S, Risso's Dolphin. T. Susu (after Anderson). U. White Whale

large and broad, with few phalanges. Food, fishes, captured by probing the mud with the long, narrow jaws, which have numerous teeth; as well as Crustacea and probably other small animals.

Platanista gangetica, Susu (fig. T, p. 172; 8 ft.). Blind; dorsal fin reduced; remarkable, large bony crests at the base of the rostrum. Teeth about 30 on either side of each jaw. Ganges, Indus and Brahmaputra, nearly to their head waters.

Family 4.—*Iniidae*. Inhabiting rivers and fresh-water lakes. Neck vertebrae large, not fused; pterygoid bones not completely covering palatine bones on ventral aspect of skull; maxillary with a more or less fenestrated process projecting backward freely below level of orbit; beak elongated; flippers large and broad. Food, mainly fishes.

Lipotes vexillifer (8 ft.), with a reduced dorsal fin, is whitish all over, its upper jaw curved upwards. Teeth about 32. Tung Ting lake, about 600 mi. from the mouth of the Yangtze Kiang river.

Inia geoffrensis (8 ft.), also with a reduced dorsal fin. The beak is covered with numerous short hairs, a primitive feature. Teeth, 30–32. Amazon river, from near its head waters.

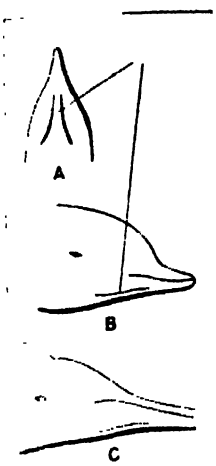

FIG. 9.—HEADS OF ZIPHIOIDS
A. Hyperoodon, young, side view
Epiodon, side view
Epiodon bidens, adult female

Family 5.—*Delphinidae*, dolphins (fig. 1) and porpoises. Dorsal fin present or absent; Tail (fig. 7, B) with a notch at the junction of the flukes.

Subfamily A.—*Delphininae*. Dorsal fin present, except as noted below. Fore flippers generally pointed and sickle-shaped. Neck vertebrae mostly fused with one another. Teeth (except *Gramphidelphis*) in both jaws, usually numerous. The numbers recorded below (on either side of each jaw) do not include the reduced teeth commonly found at the front end on both jaws below the gum. Alisphenoid not overspread by pterygoid and no external reduplication of pterygoid.

Delphinus delphis, common dolphin (fig. N, p. 172; 8 ft.). Beak about 5 in. long in middle line, separated from rest of head by a distinct groove (fig. 10, A), a character obvious in representations of this animal on Greek coins and elsewhere. Mainly black above and white below, the sides with longitudinal streaks of white, tan yellow or gray. Palate of skull with two deep, longitudinal grooves. Teeth 40–50, diameter 3–3.5 millimetres. The "dolphins" which pursue flying fish and change colour when dying, are fishes (*Coryphaena*), not to be confused with the cetacean. Cosmopolitan, common in the Atlantic and Mediterranean, frequently stranded on the British coasts, but rarely on the east side of England. Food, fishes and cuttlefish. The stomach of a Mediterranean specimen was found by Dr. J. Schmidt to contain 15,191 otoliths (ear bones), indicating the recent consumption of more than 7,500 small fishes.

Prodelphinella, with many species, often spotted or with longitudinal dark lines on the sides, is oceanic. Beak and teeth as in *Delphinus*, but palate of skull not grooved.

Lissodelphis peronii. Black and white, sharply delimited, the white including the flippers and continued past the mouth to the lower side of the "forehead." Dorsal fin wanting. Teeth as in *Delphinus*. Southern seas, with one record from New Guinea.

Lagenorhynchus. Beak short, usually distinct (fig. 10, B); sides generally with oblique light areas; upper and lower keels of middle of tail strongly marked; vertebrae numerous, about 73–92. The two following British species, also found in eastern United States, reach 9 ft., the beak 2 in. long in the middle line:—*L. albirostris*, white-beaked dolphin (fig. O, p. 172); upper lip white; teeth 22–25, diameter 7 millimetres.—*L. acutus*, white-sided dolphin, upper lip black; very distinct light areas on the sides; teeth 30–34, diameter 4 millimetres. Other species in Indian, Pacific and Southern oceans.

Cephalorhynchus (fig. Q, p. 172). Small dolphins, about the size of the common porpoise, from southern seas, usually conspicuously coloured and without sharply marked beak. Teeth 25–31, small.

Steno rostratus (fig. P, p. 172; 8½ ft.). Mainly dark, spotted with white; beak long, distinct; teeth 20–27, large, with slightly rugose crowns. Atlantic, Pacific and Indian oceans.

Sotalia. Resembling *Steno*, but teeth more numerous (up to 35), with smooth crowns. Species of *Sotalia* occur in fresh water in China (colour, milky white) and the Amazon. *S. tëuszii*, from the Cameroons, has been found to contain leaves, mangrove fruits, and grass in its stomach. Other species, from the tropical parts of the Indian and Atlantic oceans.

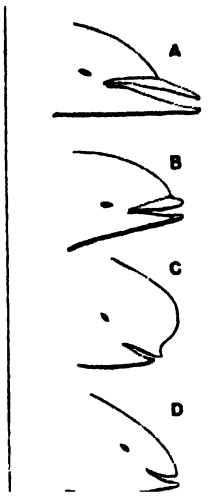

FIG. 10.—DOLPHIN HEADS
A. Delphinus
B. Lagenorhynchus
C. Globicephala
D. Phocoena

Tursiops. Beak rather longer than in *Lagenorhynchus*, teeth larger. *T. truncatus*, bottle-nosed dolphin (fig. R, p. 172; 10–11 ft.), is common in British seas and off the eastern United States. Dark above and white below; teeth 20–23, large, diameter 8.5–10 millimetres. Other species from the Mediterranean, Red sea, North Pacific, Australia and New Zealand. The natives of Moreton bay, Queensland, are said to co-operate with schools of dolphins (probably *Tursiops*) in beach fishing, the dolphins driving the fishes ashore and being rewarded for their assistance by fishes offered on the points of spears.

Gramphidelphis griseus, Risso's dolphin (fig. S, p. 172; 11 ft.). Nearly uniformly grayish; beak wanting, forehead prominent; flippers long; teeth completely absent in upper jaw (except for rare vestiges); lower teeth, 2–7, confined to the front end of the jaw, large, diameter 14 millimetres. Apparently cosmopolitan, reaching Britain and the eastern United States. "Pelorus Jack," an individual which was well known in New Zealand, a few years ago, from its habit of accompanying steamers in Pelorus sound, is believed to have belonged to this species.

Globicephala. Forehead greatly swollen and prominent (fig. 10, C); flippers specially long. *G. ventricosa*, pilot whale, blackfish or caa'ing whale (28 ft.) is black all over. Teeth 7–11, large, diameter 10–11 mm., at the front end of the jaws. Large schools have frequently been driven ashore, 1,540 individuals having been killed in two hours, in 1845, at the Shetland Islands. It is known that 117,456 individuals were captured at the Faeroe Islands between 1584 and 1883. Both sides of the Atlantic and in the Pacific, Indian ocean and southern seas.

Pseudorca crassidens, false killer (19 ft.). Teeth 8–10, almost as large as those of the killer; black all over, flippers narrow. Originally described by Owen from a subfossil skeleton from the Lincolnshire fens. Two skeletons have recently been found in the Cambridgeshire fens. A school of more than 100 specimens was stranded in the Bay of Kiel in 1861, and a school of about 150 on the east coast of Scotland in 1927. It is said to occur in large parties off New Zealand and Tasmania, and it has been recorded from India, Queensland, both sides of North America and Argentina.

Orcella brevirostris (7 ft.). Head as in *Gramphidelphis*, dorsal fin low; rostrum of skull very short; teeth 12–14, small. Ascends the Irrawaddy river, Burma, to 900 miles from the sea, and occurs in the Bay of Bengal, and off Singapore and Borneo.

Phocoena and the two following have teeth with an expanded, spade-shaped crown, differing from the conical teeth of other dolphins. *P. phocoena*, common porpoise (fig. M, p. 172; 5½ ft.), is black above and white below, with some variation. Head short, without beak (fig. 10, D), dorsal fin triangular, commonly with small, horny tubercles on its front edge. Male reproductive opening unusually far forward, below the dorsal fin; teeth 22–26. The porpoise was formerly much in request as an article of diet, and there were important fisheries off Normandy and at the entrance to the Baltic. It frequents coasts and often ascends rivers. It is

specially characteristic of the Atlantic coasts, on both sides, and it reaches the Azores. The porpoise of the Black sea and eastern Mediterranean has been considered distinct. Other species from South America.

Neomeris. Resembles *Phocoena* in having skin tubercles, but has no dorsal fin. Teeth 16–21. India and Japan (marine); Tung Ting lake and other parts of the Yangtze Kiang, hundreds of miles from the sea.

Phocoenoides, with two species from the North Pacific, also has skin tubercles. Teeth 19–22, much smaller than in *Phocoena*; vertebrae specially numerous, 95–98, as compared with 64–67 in *Phocoena phocoena*.

Grampus orca, killer or grampus (male 31 ft.; female, 16 ft.).—Beak wanting; dorsal fin large; flippers very broad, not pointed; teeth exceptionally large and strong, diameter 2 in.; colour-pattern bold, the black and light parts sharply delimited (fig. 1). The white (or yellow) extends over the lower jaw and the lower side of the tail flukes; and, just behind the dorsal fin, is produced backwards as a lobe defined below by a tongue of black passing forwards from the tail; a conspicuous white area, above and behind the eye; and a less distinct triangular mark behind and below the dorsal fin. The male is nearly twice the length of the female and all its fins increase greatly in size with age, to an extent disproportionate to the body length. The dorsal fin, at first recurved as in the female, becomes an erect triangle 5½ ft. high. The flippers reach a size of 6x4 ft., their enlargement being due mainly to the inordinate growth of the cartilage of the phalanges. Food, fishes and marine mammals and birds. Eschricht found the remains of 13 porpoises and 14 seals in the stomach of a killer, and gave reasons for believing that seals are flayed after being swallowed, the skins being then disgorged. The story that killers combine to attack a large whale, forcing its mouth open and eating the tongue, has recently been confirmed by R. C. Andrews. Although a killer should be regarded as a dangerous animal there seems to be little evidence that it willingly attacks man. The motive for a combined assault, by a party of killers, on an ice floe, as recorded in *Scott's Last Voyage*, may have been the capture of the dogs (mistaken for seals), and not of the man. *G. orca*, if all killers belong to one species, is cosmopolitan, extending from pole to pole, though it is apparently not often found in the tropics. It is not uncommon in British and American waters.

Feresa. Relatively little is known regarding this porpoise.

Subfamily B.—*Stenodelphinae.* Dorsal fin present; neck vertebrae free; flippers broad and bluntly rounded distally; beak slender. Teeth, 58–62 on either side of upper and lower jaws, of normal delphine type. Alisphenoid overspread by pterygoid; external and internal reduplications of pterygoid large.

Stenodelphis (or *Pontoporia*) *blainvillii* (5 ft.). Dorsal fin well developed; jaws long and delicate; teeth 50–60. La Plata estuary.

Subfamily C.—*Monodontinae.* No dorsal fin; neck vertebrae free; flippers broad. Teeth tusklike in manner of growth, reduced to one or two forward projecting tusks. Alisphenoid not overspread by pterygoid; no external reduplication of pterygoid.

Monodon monoceros, narwhal (fig. 1), p. 170; 15–20 ft.). Adult grayish-white, with leopardlike spots, sometimes whitish when old; young unspotted; teeth unlike those of any other animal, reduced (except for vestiges in the foetus) to a single upper pair. In females these remain concealed in the bone, but the left one exceptionally develops as in the male. The right tooth of the male remains similarly concealed, but the left tooth, the horn of the traditional Unicorn, grows spirally to an enormous length, up to 9 ft., 4½ in., projecting forwards from the upper lip. In rare cases the asymmetry may be reversed, the right tooth becoming the tusk; or the animal has two tusks, about equally developed. One or two "bidental" specimens have been recorded as female, but further evidence on the sex is required. Arctic, rarely reaching Britain. Large numbers of narwhals are killed by the Eskimos in certain parts of Greenland, where the males protrude their tusks through holes in the ice when they rise to breathe.

Subfamily D.—*Delphinapterinae.* Dorsal fin wanting; neck vertebrae free; flippers broad; dermis of skin more developed than usual. Teeth tusklike in manner of growth; not more than ten teeth on either side of upper jaws, and eight in lower jaws. Alisphenoid overspread by pterygoids; reduplications of pterygoids small. Food, mainly cuttlefish, but also fishes.

Delphinapterus leucas, white whale or Beluga (fig. 1, p. 172; 18 ft.). Adult pure white all over, young dark brown-gray; teeth 8–10, diameter 20 millimetres. Arctic and circumpolar, reaching the St. Lawrence and (rarely) the British coast. Formerly hunted on a large scale.

(S. F. H.; X)

CETATEA ALBA, a town of Rumania (Akkerman, in old Slav, *Byelgorod, i.e.*, white town) in lat. 46° 12′ N., long. 30° 17′ E., on the right bank of the estuary (liman) of the Dniester, 12 mi. from the Black sea. The town stands on the site of the ancient Milesian colony of Tyras. Centuries later it was rebuilt by the Genoese and named Mauro Castro. The Turks captured it in 1484. In 1770, 1774 and 1806 the Russians captured it, but each time returned it to the Turks. In 1826 a treaty was concluded there between Russia and the Porte, when Russia secured considerable advantages: the terms of the treaty were not observed and war broke out in 1828. In 1881 it was definitely annexed to Russia but in March 1918, when Bessarabia was united with Rumania Cetatea Alba became a Rumanian town. The harbour is too shallow to admit large vessels, but there is a trade in wine, salt, fish, wool and tallow. The salt is obtained from the saline lakes (limans) in the neighbourhood. The town and its suburbs contain beautiful gardens and vineyards. It is surrounded by ramparts and commanded by a citadel. Pop. (1930) 33,495. Rumania ceded the town, with Bessarabia, to the U.S.S.R. in June 1940, but regained it in 1941 during the German invasion of the soviet union.

CETHEGUS, the name of a Roman patrician family of the Cornelian gens. Two individuals are of some importance:—

(1) MARCUS CORNELIUS CETHEGUS, pontifex maximus and curule aedile, 213 B.C. In 211, as praetor, he had charge of Apulia; later, he was sent to Sicily, where he proved a successful administrator. In 209 he was censor, and in 204 consul. In 203 he was proconsul in Upper Italy, where, in conjunction with the praetor P. Quintilius Varus, he defeated Mago, Hannibal's brother, in Insubrian territory, and obliged him to leave Italy. He died in 196. He had a great reputation as an orator, and is characterized by Ennius as "the quintessence of persuasiveness" (*suadae medulla*). Horace (*Ars Poët.* 50; *Epistles*, ii, 2. 117) calls him an authority on the use of Latin words.

See Livy xxv, 2; 41, xxvii, 11, xxix, 11, xxx, 18.

(2) GAIUS CORNELIUS CETHEGUS, the boldest of Catiline's associates, joined the conspiracy in the hope of getting his debts cancelled. When Catiline left Rome in 63 B.C., Cethegus remained behind as leader of the conspirators with P. Lentulus Sura. He undertook to murder Cicero and other prominent men, but was hampered by the dilatoriness of Sura. He was condemned to death, and executed, with Sura and others, on the night of Dec. 5.

See Sallust, *Catilina*, 46–55; Cicero, *In Cat.* iii, 5–7; Appian, *Bell. Civ.* ii, 2–5; *see* also CATILINE.

CETINA, GUTIERRE DE (1518?–1572?), Spanish poet and soldier, was born at Seville. He served under Charles V in Italy and Germany, but retired from the army in 1545 to settle in Seville. Soon afterwards, however, he sailed for Mexico, where he spent most of the rest of his life. He was killed in a street brawl in Los Angeles. A follower of Boscan and Garcilaso de la Vega. Cetina adopted the doctrines of the Italian school and, un-

der the name of Vandalio, wrote an extensive series of poems in the newly introduced metres; his sonnets are remarkable for elegance of form, but his other productions are mostly adaptations from Petrarch, Ariosto and Ludovico Dolce. His works have been well edited by Joaquín Hazañas y la Rúa (Seville, 1895).

See A. M. Withers, *The Sources of the Poetry of Gutierre de Cetina*, etc. (1923).

CETINJE (Serbian, *Tsetinye*), capital of former kingdom of Montenegro, Yugoslavia, in a narrow plain deep in the limestone mountains, 2,068 ft. above the sea. Pop. (1931) 6,367. On one peak stands the white dynastic tomb erected by its last ruler, and on another the old bell tower formerly used for the heads of Turks. The country is bare and stony, with cultivated rich red soil in rock crevices. Winter snow and spring and autumn floods make communications difficult. Cetinje contains two parallel streets of whitewashed cottages, connected by smaller ones; the church (1478) of a fortified monastery, visited by pilgrims to the tomb of Peter I (1782–1830); the old palace, the residence of the late King Nicholas and his heir; the court of appeal; a school; barracks; a seminary for priests and teachers, established by the tsar Alexander II (1855–81); a library and reading room; a theatre; a museum; a hospital; a bank, and a war memorial. The girls' school founded by the tsaritsa Marie was closed in 1913. Near the old palace stood the celebrated plane tree beneath which Prince Nicholas gave audience until the end of the 19th century. Near the modern palace, in a glass house, guarded by a sentry, is a contour map of the country, some 60 ft. long, on which every fort, town, village, road and stream is depicted. A zigzag highway, a triumph of engineering, winds through the mountain passes between Cetinje and Cattaro, passing the impregnable Mt. Lovčen. Here Peter II (1830–51), the poet ruler, is buried. He introduced a prison and a printing press, but the latter was soon melted down for bullets. There is little trade, though mineral waters are manufactured. Cetinje owes its origin to Ivan the Black, who was forced in 1484 to withdraw from Zhabliak, his former capital. In 1941, with the dismemberment of Yugoslavia, the town and the whole of Montenegro came under Italian control.

CETTE (SÈTE), a seaport of southern France in the department of Hérault, 18 mi. S.W. of Montpellier, at the junction of the P.L.M. and Midi railways. Pop. (1936) 35,306. After Marseille it is the principal commercial port on the south coast of France. The port was created in 1666 by the agency of Colbert, minister of Louis XIV, and according to the plans of Vauban; toward the end of the 17th century its development was aided by the opening of the Canal du Midi. The older part of Cette occupies the foot and slope of the isolated Mont St. Clair (590 ft.), situated on a tongue of land between the Mediterranean and the lagoon of Thau. This well-built quarter is bounded on the east by the Canal de Cette, which leads from the lagoon of Thau to the Old Basin and the outer harbour. Across the canal lie the newer quarters, which chiefly occupy two islands separated from each other by a wet dock and bounded on the east by the Canal Maritime, parallel to the Canal de Cette. A lateral canal unites the northern ends of the two main canals. A huge breakwater protects the entrance to the harbour, which is one of the safest in France. The outer port and the Old Basin (the fishing harbour) are enclosed by a mole to the south and by a jetty to the east. Behind the outer port lies an inner basin which communicates with the Canal Maritime. The entire area of the harbour, including the canals, is 111 acres with a quayage length of more than 8,000 yards. The public institutions of Cette include tribunals of commerce and of maritime commerce, councils of arbitration in commercial and fishing affairs, an exchange and chamber of commerce. Cette is much resorted to for sea bathing. The town is connected with Lyons by the canal from the Rhône to Cette, and with Bordeaux by the Canal du Midi. The shipping trade is carried on with South America, the chief ports of the Mediterranean, and especially with Spain. The chief exports are wines, brandy and chemical products; the chief imports are coal, timber, petroleum and chemical substances. Small craft are employed in the sardine, tunny, cod and other fisheries. Shellfish are obtained from the lagoon of Thau. There are factories for the pickling of sardines, for the manufacture of liqueurs and casks, and for the treatment of sulphur, phosphates and nitrate of soda. The Schneider company of Creusot also have metallurgical works at Cette, and there are wire-making establishments.

CETUS ("The Whale"), in astronomy, a constellation of the southern hemisphere, fabled by the Greeks to be the monster sent by Neptune to devour Andromeda, but which was slain by Perseus. It contains the long-period variable star Mira Ceti (*o* Ceti), which was the first star recognized to be variable (by Fabricius in 1596). It usually ranges from the ninth to the third magnitude in about 340 days; but this kind of variation is always rather irregular. It has recently been found to have a companion distant rather less than a second of arc. The companion was first suspected from spectroscopic observations; when looked for visually it was easily seen, but it is difficult to understand why it had escaped notice in a star which was so continually studied. The companion is itself a very interesting star, possessing an unusual type of spectrum with bright lines. (A. S. E.)

CETYWAYO (d. 1884), king of the Zulus, was the eldest son of King Umpande or Panda and a nephew of the two previous kings, Dingaan and Chaka. Cetywayo was a young man when in 1840 his father was placed on the throne by the aid of the Natal Boers; and three years later Natal became a British colony. Cetywayo had inherited much of the military talent of his uncle Chaka, the organizer of the Zulu military system, and chafed under his father's peaceful policy towards his British and Boer neighbours. Suspecting Panda of favouring a younger son, Umbulazi, as his successor, Cetywayo made war on his brother, whom he defeated and slew at a great battle on the banks of the Tugela in Dec. 1856. In the following year, at an assembly of the Zulus, the management of the affairs of the nation was entrusted to Cetywayo, though the old chief kept the title of king. Cetywayo was, however, suspicious of the Natal government, which afforded protection to two of his brothers. The feeling of distrust was removed in 1861 by a visit from Theophilus Shepstone, secretary for native affairs in Natal, who induced Panda to proclaim Cetywayo publicly as the future king. Friendly relations were then maintained between the Zulus and Natal for many years. In 1872 Panda died and Cetywayo was declared king, Aug. 1873, in the presence of Shepstone, to whom he made promises to live at peace with his neighbours and to govern his people more humanely. These promises were not kept. Cetywayo's attitude became menacing; he allowed a minor chief to make raids into the Transvaal, and seized natives within the Natal border.

Sir Bartle Frere, who became high commissioner of South Africa in March 1877, was convinced that the Kafir revolt of that year on the eastern border of Cape Colony was part of a design or desire "for a general and simultaneous rising of Kafirdom against white civilization"; and in Dec. 1878 Frere sent the Zulu king an ultimatum, which, while awarding him the territory he claimed from the Boers, required him to make reparation for the outrages committed within the British borders, to receive a British resident, to disband his regiments, and to allow his young men to marry without the necessity of having first "washed their spears." Cetywayo, who had found a defender in Bishop Colenso, vouchsafed no reply, and Lord Chelmsford entered Zululand, at the head of 13,000 troops, on Jan. 11, 1879, to enforce the British demands. After the initial disaster of Isandhlwana and the defense of Rorke's Drift the Zulus were utterly routed at Ulundi (July 4). Cetywayo became a fugitive, but was captured on Aug. 28. His kingdom was divided among 13 chiefs and he himself taken to Capetown, whence he was brought to London in Aug. 1882. While he was in England the Gladstone government decided upon his restoration. Restoration, however, proved to refer only to a portion of his old kingdom. Even there one of his kinsmen and chief enemies, Usibepu, was allowed to retain the territory allotted to him in 1879. Cetywayo was reinstalled on Jan. 29, 1883, by Shepstone, but his enemies, headed by Usibepu, attacked him within a week, and after a struggle of nearly a year's duration he was defeated and his kraal destroyed. He then took refuge in the native reserve, where he died at Ekowe, on Feb. 8, 1884.

His son Dinizulu was exiled to St. Helena (1889–98), and was then allowed to return home and become a chief. He was arrested in Dec. 1907 for alleged complicity in a Zulu revolt, and in Nov. 1908 was tried before a special court. His defense was undertaken by Mr. W. P. Schreiner. The charge of treason was not proved, but he was convicted of harbouring rebels and sentenced to four years' imprisonment.

The Life of Sir Bartle Frere, by John Martineau, vol. ii, ch. 18 to 21, contains much information concerning Cetywayo.

CEUTA (Arabic SEBTA), a Spanish military and convict station and seaport on the north coast of Morocco, in 35° 54′ N., 5° 18′ W. Pop. (census, 1945) 60,353. It is situated on a promontory connected with the mainland by a narrow isthmus, and marking the southeastern end of the Straits of Gibraltar, which between Ceuta and Gibraltar have a width of 14 miles. The promontory terminates in a bold headland, the Montagne des Singes, with seven peaks, of which the highest, the Monte del Hacko—the ancient Ablya, one of the "Pillars of Hercules"—rises 636 ft. above the sea.

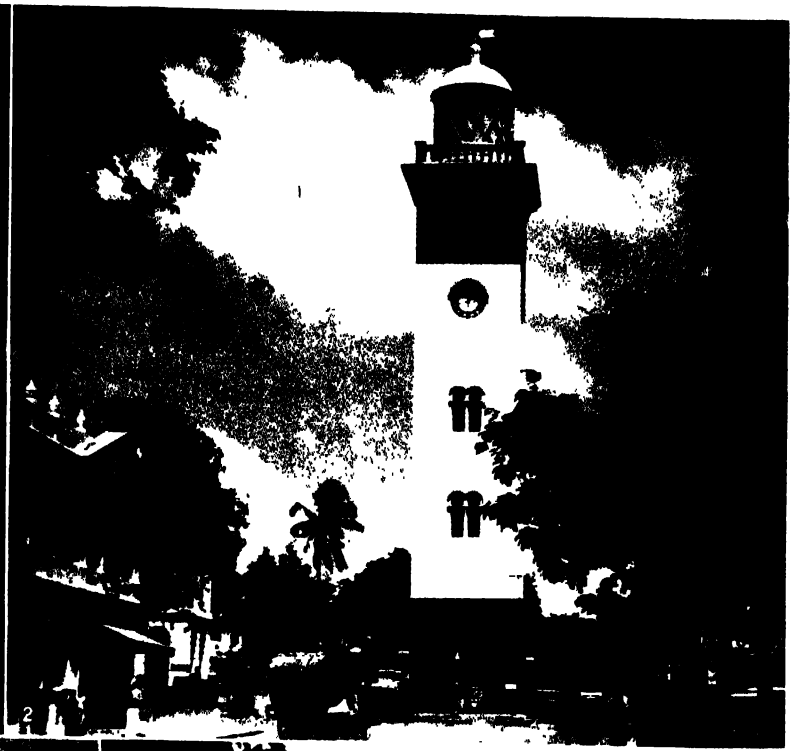
Ceuta occupies in part the site of a Carthaginian colony, which was succeeded by a Roman colony said to have been called *Ad Septem Fratres* and also *Exilissa* or *Lissa Civitas*. From the Romans the town passed to the Vandals and afterward to Byzantium, the emperor Justinian restoring its fortifications in 535. In 618 the town, then known as Septon, fell into the hands of the Visigoths. It was the last stronghold in North Africa which held out against the Arabs. At that date (A.D. 711) the governor was Count Julian, who, to avenge a family wrong, invited the Arabs to conquer Spain. The Arabs called the town Cibta or Sebta, hence the Spanish form, Ceuta. It was repeatedly captured by rival Berber and Spanish-Moorish dynasties but became, nevertheless, an important industrial and commercial city, being noted for its brassware and its trade in ivory, gold and slaves. It is said to have been the first place in the west where a paper manufactory was established. In 1415 the town was captured by the Portuguese. It passed to Spain in 1580 on the subjugation of Portugal by Philip II, and was definitely assigned to the Spanish crown by the Treaty of Lisbon in 1688. The town has been several times unsuccessfully besieged by the Moors, one siege, under Mulai Ismail, lasting 26 years (1694–1720). In 1810, with the consent of Spain, it was occupied by British troops, but was restored to Spain at the close of the Napoleonic Wars. Its territory was enlarged after the war between Spain and Morocco in 1860.

Ceuta consists of two quarters, the old town, covering the low ground of the isthmus, and the modern town, built on the hills forming the north and west faces of the peninsula. Between the old and new quarters, and on the north side of the isthmus, lies the port. The fortifications date from the Portuguese occupation. For civil purposes Ceuta is attached to the province of Cadiz. It is a free port. Trade increased markedly during World War II.

CEVA, TOMASSO (1648–1736), Italian mathematician, was born at Milan on Dec. 20, 1648. He taught mathematics at the Jesuit college in Milan, and was a member of the order. While at the Brera college he co-operated with Saccheri in a number of mathematical researches. In 1678 Ceva published some work containing the theorem which is known by his name and which deals with the concurrency of straight lines through the vertices of a triangle. He died at Milan on Feb. 3, 1736.

CEVA, a town of Piedmont, Italy, province of Cuneo, 33 mi. E. by rail from the town of Cuneo, on the line to Savona, 1,270 ft. above sea level. Pop. (1951) 5,567 (commune). The mediaeval fortress (defending the confines of Piedmont toward Liguria) was destroyed by the French in 1800, after cession to them in 1796. Cevan cheese (*caseus cebanus*) was famous in Roman times. A branch railway runs from Ceva through Garessio, with its marble quarries, to Ormea (2,398 ft.), 22 mi. to the south through the upper valley of the Tanaro. From Ormea a road runs south to (31 mi.) Oneglia on the Ligurian coast.

CÉVENNES, a mountain range of southern France, forming the south and east fringe of the Plateau Central and part of the watershed between Atlantic and Mediterranean basins. It consists of a narrow ridge some 320 mi. long, with numerous lofty plateaux and secondary ranges branching from it. The northern division, nowhere over 3,320 ft., is called the mountains of Charollais, Beaujolais and Lyonnais, from the Col de Longpendu (west of Châlon-sur-Saône) in a southerly direction to the Col de Gier. The central Cévennes, comprising the volcanic chain of Vivarais, incline southwest and extend as far as the Lozère group. The northern portion of this chain forms the Boutières range. Farther south it includes the Gerbier des Joncs (5,089 ft.), the Mont de Mézenc (5,750 ft.), the culminating point of the entire range, and the Tanargue group. South of Mont Lozère, where the Pic Finiels reaches 5,584 ft., lies the range strictly called the Cévennes. This region stretches south to include the Aigoual and Espérou groups. Under various local names (the Garrigues, the mountains of Espinouse and Lacaune) and with numerous offshoots, the range extends southwest and then west to the Montagne Noire. In the south, the Cévennes separate the barren region of the Causses from sunny Languedoc, where olive, vine and mulberry flourish. Northward the contrast between the two slopes is less striking.



The Cévennes proper are a folded belt of Palaeozoic rocks along the southeast border of the central plateau of France. Concealed in part by later deposits, these folds extend from Castelnaudary to near Valence, where they sink suddenly beneath the Tertiary and recent deposits of the Rhône valley. Rocks from Cambrian to Carboniferous are included in the folded belt, and the gneiss and schist which form so much of the chain consist, in part at least, of metamorphosed Cambrian beds. The structure is complicated by extensive overthrusting from the southeast. The principal folding is of Hercynian age. Permian and later beds lie unconformably upon the denuded folds, and in the space between the Montagne Noire and the Cévennes proper the folded belt is buried beneath the horizontal Jurassic strata of the Causses. Folding was renewed along the southeast margin at the close of the Eocene period. The Secondary and Tertiary beds of Languedoc were crushed against the central plateau and were frequently overfolded, but the ancient Palaeozoic chain acted as part of the unyielding massif, and the folding did not extend beyond its foot.

The Cévennes form the watershed between the basins of the Loire and the Garonne to the west and those of the Saône and Rhône to the east. In the south the Orb, the Hérault and the Vidourle flow directly into the Gulf of Lyons; farther north, the Gard, the Cèze and the Ardèche flow to the Rhône. The Vivarais mountains and the northern Cévennes approach the right banks of the Rhone and Saône closely, and short torrents flow down to those rivers; on the west side the streams are tributaries of the Loire, which rises at the foot of Mont Mézenc. A short distance to the south on the same side are the sources of the Allier and Lot. The waters of the northwestern slope of the southern Cévennes drain into the Tarn. In the Lozère group and the southern Cévennes generally, is good summer pasturage for huge flocks. Silkworm-rearing and the cultivation of peaches, chestnuts and other fruits are also carried on. In the Vivarais cattle are reared, while on the slopes of the Beaujolais are flourishing vineyards.

CEYLON, a large island in the Indian ocean and a self-governing member of the Commonwealth of Nations. It is 272 mi. long and 140 mi. wide at its broadest part and has an area of 25,332 sq.mi., about half the size of England. It lies between 5° 55′ and 9° 50′ N. and between 79° 42′ and 81° 52′ E., and is situated southeast of Cape Cormorin in India, from which it is separated by the 30-mi.-wide Palk strait.

Physical Features.—Except for a few rocky promontories, such as at Trincomalee, the low coast of Ceylon is subject to erosion, although a coral reef a few hundred yards out to sea prevents serious damage. The coast is beset on the northwest by shoals and rocks, and the island of Mannar (Manaar), which forms an integral part of Ceylon, is almost joined to the Indian mainland by a chain of sandy islets known as Adam's Bridge, just north of which a daily ferry service runs from Talaimannar to Dhanushkodi on the Indian coast. The west coast, from Puttalam southward, and the whole of the south coast are fringed by coconut palms which grow to the water's edge; but the east coast is more rugged and, except along a short stretch north and south of Bat-

ticaloa, the palms of the south and west are replaced by scrub jungle starting at high-water mark. Round the northern and north-western end of the island palmyra palms grow on the low shores and, where cultivation is absent, scrub jungle is found. Deep water is usually available close to the reef, though there are a few dangerous rocks well known to navigators.

The centre of the broad southern end of Ceylon consists of a mountain massif, covering about 4,000 sq.mi. and known as Up Country, in contrast with the Low Country or surrounding coastal plain from which, about 45 to 60 mi. inland, rise the foothills. This massif intercepts the rains of both monsoons, or periods of more or less constant wind, bringing rain from the southwest during the period April to September, and from the northeast from October to March. Thus April to September constitutes the wet season in the southwest and the dry season in the northeast, whereas conversely October to March is the dry season in the southwest and the wet season in the northeast.

Although the two monsoons form the main feature in the Ceylon climate, the factors of total annual rainfall and elevation above sea level also have the effect of creating a wet and a dry zone, quite distinct from the monsoons or seasons. As a result of these phenomena the mountains, with the western plain, comprise the wet zone, where the annual rainfall in places reaches 200 in., and the vegetation, both cultivated and natural, differs entirely from that of the northern and eastern plains, which form the dry zone, with an average rainfall of less than 50 in. a year.

Among the 150 mountains, ranging in height from 3,000 to 7,400 ft., the most famous, because of its religious associations, is Adam's Peak (7,360 ft.), but the highest summit is Pidurutalagala (8,274 ft.) near the highland health resort of Nuwara Eliya (6,000 ft.), where the temperature is cool, with frost at night in December and January, but no snow or natural ice.

THE TISSAMAHARAMA DAGOBA. DAGOBAS ARE HEMISPHERICAL STRUCTURES BUILT WITH BRICKS, AND USUALLY CONTAIN A RELIC OF THE LORD BUDDHA, OR OF A BUDDHIST SAINT

The climate of the Low Country is hot, particularly from March to May, the average mean temperature ranging from 79° to 82° F., combined with a high degree of humidity in the wet zone. The length of the day does not vary more than an hour at any season because of the proximity of Ceylon to the equator. Colombo is situated in 79° 50′ 45″ E., and the day is further advanced there than at Greenwich by 5 hr. 19 min. 23 sec.

The largest river in Ceylon, the Mahaveli, draining the eastern slopes of the mountains, falls into the sea near Trincomalee after a 206-mi. course which, like that of all rivers in Ceylon, is navigable by small boats only in its lower reaches because of rapids upstream. The next largest river is the Malwatte (104 mi.) or Aruvi (Tamil), which reaches the west coast at Arippu, just south of Mannar. No other river in Ceylon is 100 mi. long, but the Deduru, Kelani and Kalu, all of considerable size, drain the western slopes, with the Walawe and Gin flowing to the south.

Flora.—The species of plants in Ceylon number between 3,000 and 4,000. Their distribution varies a great deal according to the rainfall. Equatorial rain forest is predominant in the hill country, except where it has been replaced by tea or rubber, and xerophytic jungle and scrub in the dry parts of the east and north. There are open tracts of grassland called *patanas* in the drier areas of the hill country, and in the lowlands to the east are some regions of richer grassland.

Round the coast the mangrove grows on muddy shores, screw pines (*Pandanus ceylanicus* and *P. tectorius*) where it is sandy, coconuts and other palms along the southwest and south coasts and palmyra palms in the north. The forests of the wet zone grow much higher than in the dry and produce certain valuable woods such as *nedum* and calamander. Among the many beautiful varieties of flowering trees are the flame tree, tulip tree, golden shower (*Cassia fistula*), *Datura fastuosa* and *Amherstia nobilis*. At the high elevations orchids flourish, in particular the Wesak orchid (*Dendrobium MacCarthiae*), and the trees become lower and flat-topped with rhododendrons much in evidence. In the dry zone there is much low scrub jungle and, farther inland, forests with valuable timber such as satinwood, ebony and milla.

Beside the Low Country jungle streams huge kumbuk trees grow, while everywhere there are climbing plants and epiphytes of many kinds, among them the brilliant orange-red *Gloriosa superba*. The jak tree, euphorbias, cacti, guava and castor oil are among the plants found almost all over the island. On pools and abandoned tanks East Indian lotus (*Nelumbo nucifera*) is often seen. Colombo is famous for its flowering trees, and in March and April Ceylon is prolific in flowers of all kinds, including almost all those grown in English gardens. Up Country gardens produce many English vegetables. The herbaceous plants of the dry zone belong largely to the families Leguminoseae, Acanthaceae and Scrophulariaceae.

Fauna.—The density of highly civilized population round Colombo in the southwest makes it easy to forget that two-thirds of Ceylon is under thick jungle, inhabited principally by wild animals which, however, find it increasingly difficult to survive in spite of the protection afforded by the game department and the society for the protection of fauna.

The most interesting and important animal in Ceylon is the elephant, a subspecies of the Indian form, seldom developing tusks, which, after it has been domesticated, is largely used for haulage of timber where there are no roads and for handling heavy weights in construction work. Elephants, adorned with sumptuous cloths and trappings, also play a prominent part in religious processions, carrying the sacred Buddhist relics. Though much scarcer than when the island was still almost uncleared of jungle, there are still a number of herds of wild elephants in the forests from which recruits to the ranks of domestic elephants are taken. The herd is shepherded into a kraal or stockade by means of a gradually enveloping drive, carried out by hundreds of men over a period of several weeks. Once inside the stockade the wild elephants are noosed by the hind legs and tied to trees, an operation requiring both skill and courage. The recruit, after his excitement has subsided, is then led away by two tame elephants, from whom he soon learns his duties and becomes a useful work animal.

The small domestic cattle are hardy and are capable of drawing heavy loads in single- or double-yoked carts, but they are usually rather underfed because of lack of good pasture and therefore are neither good milk producers nor fat for eating.

The water buffalo (*Bubalus bubalis*) is common, both tame and,

in the more distant jungles, wild. Domestic buffaloes are used to plow rice fields and to tread out grain, but otherwise lead a semi-wild life, except for a small number kept in dairies.

Ceylon possesses four kinds of deer: the sambar or "Ceylon elk" (*Cervus unicolor*); the spotted deer (*Axis axis*); the barking deer (*Muntiacus muntjak*); and the hog deer (*Axis porcinus*), now almost extinct in Ceylon. A little chevrotain, the mouse deer (*Tragulus meminna*), is common. There are no antelopes.

Three species of monkeys are found: the small brown toque monkey (*Macaca sinica*), which abounds, and two langurs known as *wanduru* (*Presbytis senex* and *P. entellus*). The only other member of the primates is the little slender loris (*Loris tardigradus*), which creeps about the trees at night eating fruit and catching small birds and insects while they are asleep. Twenty-seven Chiroptera have been identified, among them the large fruit-eating bat, the Indian flying fox (*Pteropus giganteus*). This bat roosts in noisy, quarrelsome colonies, hanging upside down all day in tall trees. At evening these huge bats fly in long procession to mango gardens and fig trees, where they do considerable damage.

Lions and tigers are not found in Ceylon, but the leopard is common, as also are smaller wild cats, such as the fishing cat, polecat and civets of various species. The only dangerous carnivore is the sloth bear (*Melursus ursinus*), which, when surprised, attacks on sight. It is common in the wilder jungles, where Sinhalese bearing marks of its savagery are not infrequently met.

Otters are not rare in the hills; wild pigs are abundant and the ubiquitous jackal is familiar to children in the role of "Nariya," a clever, likable rascal corresponding to Br'er Fox. There are several species of mongooses and squirrels, including the flying squirrels, which, by means of the skin stretched between their legs and tails, can glide down from a height for a considerable distance. The tree rat is found in gardens and houses all over the island, having become as urban as a London wood pigeon. The brown rat and the bandicoot rat, which grows up to two feet long, are common everywhere. House mice abound, as do shrews, usually called in English "muskrats" because of their smell, although their Tamil name means "gloomy face." The porcupine (*Hystrix indica*) damages young rubber trees, and hares provide considerable sport, even in semiurban areas. The only representative of the Edentata is the scaly anteater or pangolin (*Manis crassicaudata*), which, being entirely nocturnal, is seldom seen.

About 372 species of birds are recorded, approximately 120 of which are winter migrants from Asia and 50 others occasional visitors. Of the remaining 200 residents, about 60 species are endemic. Among these indigenous species the most noteworthy are the Ceylon jungle fowl (*Gallus lafayetti*), the blue magpie (*Cissa ornata*), the yellow-eared bulbul (*Kelaartia penicillata*), the gray-headed babbler (*Turdoides cinereifrons*), the red-faced malkoha (*Phoenicophaes pyrrhocephalus*), the green-billed coucal (*Centropus chlororhynchus*) and Legge's flowerpecker (*Acmonorhynchus vincens*). The avifauna of the south includes most endemic species and shows a close affinity to that of the Travancore hills, while the birds of the dry, flat north are more like those of the Carnatic. Bulbuls, babblers, barbets, kingfishers, cuckoos and crows are ubiquitous, while thrushes, flycatchers, chats, drongos, mynahs, sunbirds, parakeets, woodpeckers, hawks and owls are all well represented. Pigeons of several kinds and game birds are common, the latter including peafowl, jungle fowl, numerous kinds of duck, partridge and snipe. The large artificial lakes, known as "tanks," in the dry zone are frequented by herons, storks, flamingoes, egrets, spoonbills and waders in thousands, especially in the nesting season, when the bushes and trees at the water's edge are white with birds. Terns are the most numerous sea fowl, gulls being only winter visitors.

The only kinds of poisonous snakes that need be feared are the cobra (*Naja naja*), the tic-polonga or Russell's viper (*Vipera russelli*) and one or two species of krait. Other venomous kinds are either very slightly so or else are very rare. The rock or Indian python (*Python molurus*) is common in jungles, and rat snakes, grass snakes and green whip snakes are frequently encountered. The hamadryad does not live in a wild state in Ceylon.

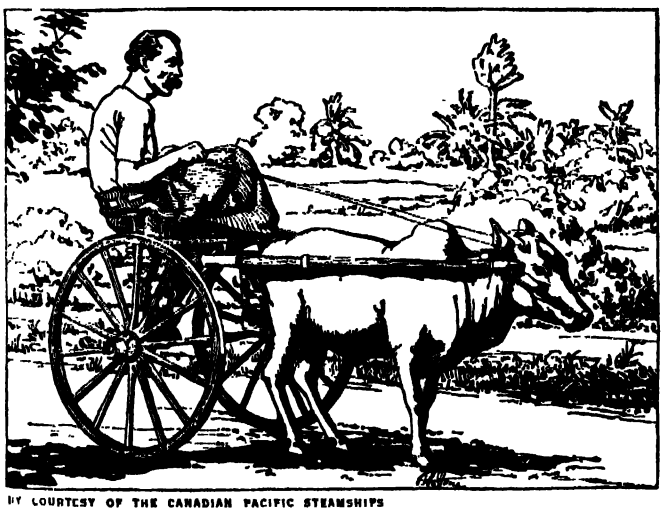
Two species of crocodile occur, the marsh crocodile or mugger (*Crocodilus palustris*) in the lakes, and the larger estuarine crocodile (*C. porosus*) in the rivers and estuaries. Both species were shot for their hides and became rare until, in 1945, they were protected by legislation, with the result that they thereafter became plentiful again. The talagoya, or common Indian monitor (*Varanus bengalensis*), and its larger relative the aquatic kabaragoya (*V. salvator*) are similarly protected and are therefore numerous. The handsome starred tortoise (*Testudo elegans*) is common, and the neighbouring seas are inhabited by several species of turtle. From the shell of the hawksbill turtle the famous tortoise-shell ware is made.

The commonest lizards are several species of the genus *Calotes*, which are erroneously called chameleons from their habit of changing colour from green and gray to red. One species (*Calotes versicolor*) is often called the bloodsucker. There are also several true chameleons and many small skinks and geckos; the latter frequent houses. Thirty-seven species of frogs and toads are recorded.

The dugong occurs in the shallow seas of the northwest, where it comes to feed upon a seaweed that grows there. It is now rare, being taken for its food value, and has been brought under legislative protection, but in the past, when it was far more plentiful, it gave rise to the mermaid legend, as a result of the female's habit of sitting almost upright in the water nursing her young one in her flippers. Sharks are common all round the island.

Of the fresh-water fish the most useful are the catfish, or lula, and the gurami; the latter is an imported species, some of which escaped from a pond in Peradeniya botanical gardens during a flood and were found multiplying profusely in the Mahaveli river several years later. The species is being distributed all over the island by the fisheries department. In Nuwara Eliya district the streams contain rainbow trout established and stocked by the fishing club. The most popular sea fish for eating is the seer, but the blood fishes, though less in demand, are much more plentiful.

The teeming invertebrate life includes ants of various kinds, termites which destroy wood, bees, hornets, butterflies and moths (some of which are brilliantly coloured and whose wing span may be anything from six inches to a fraction of an inch), many kinds of flies, spiders including the tarantula, mosquitoes, leeches on land and in water, scorpions and many others. (R. H. Br.)



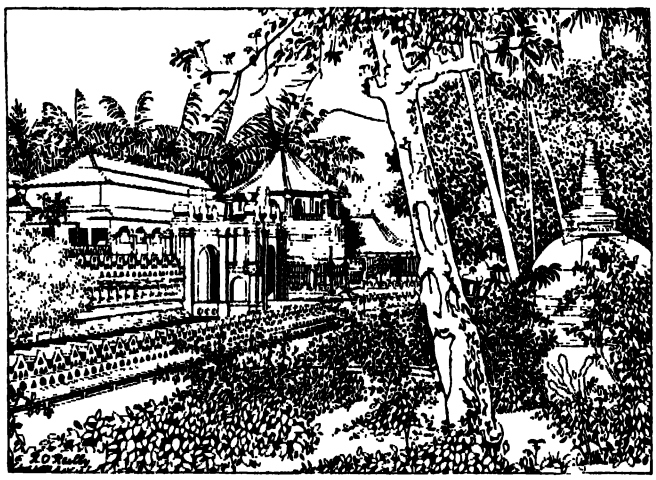
HISTORY

The island of Ceylon was known to Brahmanical literature under the name of Lanka; to the Greeks and Romans as Taprobane; to the Mohammedan seamen and merchants, who for so long had a monopoly of the sea-borne trade of the Indian ocean, as Serendib, which it has been suggested is a corruption of the Sanskrit Sinhaladvipa; and to the Portuguese as Zeylan, from which is derived its modern name. The presumed aboriginal inhabitants of the island were the people today called Veddas, a few of whom still occupy certain rock shelters in the Eastern province of the island. A careful and scientific examination of these people was made in 1910 by Brenda Seligman and C. G. Seligman. Though their language is said to have certain Indian affinities, they seem ethnologically to be related to the rather lightly coloured, wavy-haired race which is found surviving as somewhat the higher of the two principal aboriginal races in many parts of southeastern Asia. The Veddas are probably related to the Semang or Pangan of the Malay peninsula and to the Andaman islanders. Of the latter race, however, no trace has ever been found in Ceylon. The Veddas are regarded by the Sinhalese as of *goigama*—viz., husbandman–caste.

The great Hindu epic, the *Ramayana*, tells of the conquest of the greater part of the island by the hero Rama, who, with his army, crossed Adam's Bridge (*q.v.*) by the aid of the monkey god Hanuman and his host, the object of his invasion being, as in the case of Menelaus, the recovery of his wife, Sita, who had been abducted by Rawana, king of Lanka. The invaders would appear to have penetrated deep into the heart of the massif which occupies the centre of the southern portion of Ceylon. Unlike most oriental countries, Ceylon can boast a written history of considerable antiquity, the Mahavamsa. This chronicle tells of the landing of Vijaya, the first Sinhalese king, in 483 B.C., accompanied by a

small band of Aryan-speaking followers who must, it is thought, have sailed from some point on the northern or northeastern shores of the Bay of Bengal, since the greater part of southern India has, from time immemorial, been inhabited by people of Dravidian stock. Vijaya married a local princess—quite possibly a Vedda—and is said to have become the king of all Ceylon. It is noteworthy that, until the Sinhalese had been driven from the flat plains north of Dambulla by successive invaders from southern India, they appear never to have attempted to populate at all densely the forest, which of old covered the hills and valleys of the central massif and the rich, moist areas in the plains immediately surrounding it. Instead, they established themselves throughout the vast, flat, arid country to the north of Dambulla, which extends to Puttalam on the west, to Kalkuda, about 20 mi. N.N.W. of Batticaloa on the east, northward to Point Pedro in the Jaffna peninsula, and northwest to Talaimannar. This country (Pihiti was its ancient name) they rendered capable of supporting a considerable population by the construction of one of the most elaborate irrigation systems ever attempted by mankind. It may, however, safely be concluded that Ceylon is more thickly populated than it has been at any previous period of its history.

The Sinhalese kings had long been established at Anuradhapura, though their earliest capital was at Raja-Ratta, when in 246 B.C. the island was visited by Mahinda, a Buddhist priest and a son of Asoka, who is piously believed to have reached Mihintale from his father's capital, Magadha, accompanied by a few disciples, by levitation. A branch of the sacred Bo tree, seated beneath the shade of which Gautama attained to Buddhahood, was imported from Magadha and planted at Anuradhapura. Tradition tells that Gautama himself visited Ceylon, in the course of his ministrations, on three occasions, the last descent being on Adam's Peak (*q.v.*). Though he is said personally to have undertaken the instruction of the people, there is nothing to show that Buddhism became established in Ceylon before the 3rd century B.C. From that time onward, however, up to the present time, it has been the religion to which the vast majority of Sinhalese adhere. Buddhism is essentially a tolerant, nonproselytizing philosophical system, and as it spread Buddhist temples and monasteries were established in all parts of Ceylon. In the course of time, too, the Buddhist Church acquired ownership of much of the most fertile land, donated to it by the kings or by wealthy individuals. Buddhism became the state religion of Kandy, the king of which was head of the church. The word Mahavamsa means *The Genealogy of the Great*, and, as was to be expected, the priestly chroniclers, who wrote in Pali, a tongue not understood by the people, had nothing to say about them. They tell also with apparent fidelity the long, tangled story of successive murderous strivings for the throne and of the frequent invasions of northern and central Ceylon by princes and armies of southern India, one of which led to the usurpation of the throne of Anuradhapura for a period by the Tamil Elala, who was slain by the Sinhalese kingly and saintly hero Dutegemunu (*c.* 190 B.C.). The ruins of Anuradhapura as we know them today (they were buried in jungle and completely deserted and neglected until about 1845) are interesting but disappointing in that it is not easy to reconstruct from them any very vivid picture of the city in its prime. The upper structures were of timber, and all have long ago perished, leaving only the foundations for the instruction of archaeologists. The massive *dagobas*—the pyramidal structures which are veritable hills laboriously constructed of small sun-dried bricks—and some of the buildings of Polonnaruwa are in a somewhat better state of repair. Both these ancient capitals, which had for centuries been completely deserted and surrendered to the jungle by the Sinhalese, have become under British rule places of monthly pilgrimage to which hundreds of thousands of pious Buddhists annually resort. A great deal of archaeological and epigraphical work was done under government auspices by the archaeological department established by Sir William Gregory (1872–77). But the history of Ceylon under its Sinhalese kings is mainly a chronicle of royal crimes, virtues and delinquencies; of the long-drawn-out struggle with invading princes and armies from southern India; and of internecine strife between the Sinhalese kings of Pihiti (viz., northern Ceylon) and the chiefs of Rohuna and Maya-Ratta, the two districts or provinces into which the then sparsely populated southern portion of the island was divided. The last great revival of the glory of Sinhalese monarchy took place under Prakrama Bahu, who was crowned king of Pihiti in 1153 at Polannaruwa, and in 1155 king of all Lanka, after successful war against Rohuna. His reign is lovingly styled the "Golden Age of Lanka" by the past-praising Sinhalese of today; but his wars, his invasion of Pegu in Burma and of the Pandyan country in southern India, his enormous activity as a builder of nonremunerative works, such as his palace with its reputed 4,000 apartments, dancing halls, *dagobas*, monasteries and temples, as well as his construction and restoration of innumerable irrigation tanks, must have imposed an almost unendurable strain upon the energies of his subjects. Fanatically religious, he lavished land and treasure upon the priesthood, who repaid him by giving him in the Mahavamsa a superhumanly excellent character; he persecuted ruthlessly heretical Buddhist sects, which by the hierarchy was also accounted to him for righteousness; he endowed Brahmans, in a fine but hardly consistent spirit of religious toleration; and, in imitation of Asoka, he imposed vegetarianism upon his overwrought people and punished with great severity the taking of animal life either in the water or on the land. The people must have been reduced in large numbers to a condition indistinguishable from slavery, and it is certain that this great monarch did much to ruin his country economically by his improvidence. Ceylon, or more properly Pihiti, had been conquered and annexed by Indian princes on several occasions, but in 1408, in revenge for an insult offered to an envoy, a Chinese army invaded the island and carried King Vijaya Bahu IV into captivity. For 30 years Ceylon remained tributary to China.



BY COURTESY OF THE CANADIAN PACIFIC STEAMSHIPS

RACING BULLOCK CART IN CEYLON DRIVEN BY A NATIVE DRESSED IN LOCAL MALE FASHION. HE WEARS A SKIRT AND A COMB

Ceylon was first visited by the Portuguese when Francisco de Almeida landed there in 1505. He found an island divided into seven kingdoms, each ruled by its separate monarch and each frequently at odds with one or more of its neighbours. In 1517 a fort was erected at Colombo by orders of the viceroy at Goa, with the permission of the king of Cotta; and from this time onward until the end of the 16th century the Portuguese were constantly at war with one or another of the native kingdoms. It is claimed that, when attacking and conquering Jaffna (Jaffnapatam) they obtained possession of the Tooth relic, and, in spite of the enormous ransom offered for it, publicly burned it in the market place at Goa in obedience to the archbishop, who would not suffer the viceroy to make money out of the sale of what he accounted an idol. By the Sinhalese priesthood, who still possess a Tooth relic the shrine of which is at Kandy, it is asserted that the object captured at Jaffna was a false tooth. The Portuguese won a firm foothold on the western littoral, and they succeeded in converting the bulk of the *karawa* or fisher-caste Sinhalese to Christianity. Conversions upon a considerable scale, but almost in-

variably among the lower-caste sections of the population, were similarly effected in other parts of the island; as estimated in 1946, Christians numbered 603,235 or nearly 10% of the total population of Ceylon, most of them being Roman Catholics. The proselytizing fervour and cynical rapacity of the Portuguese won for them hosts of enemies among the natives of all ranks, while their inherited traditional hatred for the Moors—by which term they described all Mohammedans—rendered them peculiarly odious to the latter, whose trade and shipping monopolies they had destroyed. The French, the Dutch and the British, when in turn they set the bull of Alexander VI at defiance and forced their way into the Indian ocean, were accordingly welcomed as deliverers by the people of the east generally; and the trading centres the Portuguese had established in the beginning with such dauntless courage, where they had exploited and persecuted the native populations so ruthlessly, fell before the Dutch and the British, fighting often in alliance with native potentates.

The Dutch captain Joris Spilberg landed on the east coast of Ceylon in 1602 and was welcomed by the king of Kandy, who besought him to help in the ejection of the hated Portuguese. No action of importance was taken, however, until 1638–39, when a Dutch expedition attacked and destroyed the Portuguese forts on the east coast. In 1644 Negombo, which had once before been unsuccessfully attacked, fell to the Dutch; and in 1656 and 1658 Colombo and Jaffna were successively captured. The Dutch thus became masters of practically the whole of the maritime provinces of Ceylon, the kingdom of Kandy alone retaining its independence. The Dutch forthwith set about the task of the methodical and efficient administration of the country in a fashion never attempted by the Portuguese. They taxed the people heavily, but the land registers which they instituted have endured to this day, as also has Roman-Dutch law, many of the provisions of which are now deeply ingrained in the traditions of the Low Country Sinhalese peasantry and landholders. They also undertook public works upon a considerable scale and built excellent houses for their own accommodation, public offices, law courts and churches, many of

THE TEMPLE OF THE SACRED TOOTH AT KANDY, CEYLON

The tooth in this temple is said to have belonged to the Buddha, although the Portuguese claim to have captured the original tooth during their suzerainty over Ceylon (1517–1600), and to have burned it in the marketplace of Goa

which still survive; the roads which they made opened up the interior and greatly stimulated the trade of the island. Tolerant to Buddhism, Hinduism and Mohammedanism, they persecuted the Catholics persistently, but the religion which had been acquired by thousands of Sinhalese and by the Ceylon-born Tamils of Jaffna and Mannar was too deeply rooted in the peoples' hearts for its extirpation to be possible. Throughout the Dutch period Kandy maintained its independence.

The British, who had dispatched an embassy to the king of Kandy from Madras as early as 1762 without result, after various naval skirmishes in the neighbourhood of Trincomalee and Batticaloa, sent a well-equipped force against the Dutch in Ceylon in 1795, met with only a feeble resistance and in less than a year had obtained possession of the island. The Dutch rule had lasted for about 140 years, a period equal to that of Portuguese domination; but while the latter left Ceylon more distracted and no more developed than they had found it on their arrival, the Dutch administration, if somewhat harsh and unimaginative, worked genuine and permanent improvement in almost every branch of the social and economic life of the people. The Dutch practice, followed by them for so long in almost all their overseas possessions, of taking over oppressive local systems of taxation, which had been endurable only because evasion was so common, and thereafter applying them with ruthless efficiency made their rule highly unpopular; and even today the Burghers, who are the descendants of the former Dutch rulers and settlers, are far from being loved by the Sinhalese. These Ceylonese Dutchmen, though many of their families have dilutions of oriental blood in their veins, have retained their national character, their sturdy self-esteem, their traditions and high ideals of probity and conduct in a very remarkable degree. Over a long period they had a practical monopoly of the clerical work in most public departments and held most positions of trust in public departments and commercial houses.

At first Ceylon was administered from Madras, but an attempt to apply the Madras revenue system and the employment of a host of Malabar collectors led to a rebellion. The treaty of Amiens (1802) formally ceded Ceylon to Great Britain and it became a British crown colony; the following year Kandy was invaded and occupied. The garrison was shortly afterward treacherously massacred after it had been induced to lay down its arms. It was not till 1815, however, that the Kandyan chiefs (with some of whom at an earlier period Gov. Frederick North, later earl of Guilford, had carried on discreditable intrigues against their king) invoked the aid of the British to rid themselves of this tyrant of Malabar stock whose cruelties had surpassed endurance. The Kandyan kingdom was thus voluntarily handed over to the British crown, which guaranteed its people civil and religious liberty and the maintenance of their ancient customs. An insurrection which broke out shortly after was easily suppressed, and the second treaty (1818) which followed it did not materially alter in any respect the status of the Kandyan chiefs and people vis-à-vis the crown. The pacification and opening up of the mountain country by the construction of roads led immediately to a great incursion of Low Country Sinhalese, Mohammedan and Hindu traders and European coffee planters. These latter penetrated into the virgin forest and, aided in the task of clearing by the Sinhalese villagers, carved out estates for themselves. The indigenous inhabitants declined to work for a wage on the European estates, save as artisans, etc., and it was found necessary to import as voluntary immigrants large numbers of Tamil coolies from the arid districts of southern India. Attempts to introduce cinchona were only partially successful, but very soon tea began to be planted and by the end of the century it was covering a far larger area than coffee had ever done. Then came rubber planting, an enterprise in which, for the first time, Sinhalese planters took an active part, their energies having in the past been confined to the cultivation of coffee, which ended in disaster, to some cocoa planting and to coconut planting. Large fortunes were also made by Ceylonese in plumbago mining. The consequent acquisition of wealth by the natives of Ceylon, and especially by men of the *karawa* caste, brought about a social upheaval and led to an agitation for political reform, the real object of which (though stimulus was imparted to it by the Morley-Minto reforms in British India) was to break the monopoly which the highest-caste *goigama* aristocracy had till then enjoyed of representing Sinhalese interests in the legislative council. During the agitation that preceded the granting of these claims, ill feeling based on caste prejudice, on the angry passions which such prejudice aroused and on racial animosity began for the first time to become vocal in Ceylon. The first scheme of reform was worked out in 1909 by Col. Seely, then undersecretary of state for the colonies, and accepted by Gov. Sir Henry McCallum, in spite of the protests of his executive councillors and the obvious inapplicability of Seely's scheme as origin-

ally framed by him to local circumstances. The first election of a representative of the educated Ceylonese was fought purely on caste lines, a high-caste Tamil being chosen with the aid of the high-caste Sinhalese vote, caste prejudice thus proving to be a stronger passion than racial bias. A state of growing unrest was thus created, and this was increased by the outbreak of World War I. A religious fracas at Gampola in 1915 between the Buddhists and Mohammedans resulted in riots which were quelled only after imposition of martial law, but in spite of this Ceylon emerged from the war comparatively unscathed.

The political problems in Ceylon were rendered particularly difficult of solution because of the very heterogeneous population. The Low Country Sinhalese, more sophisticated than the Kandyans, were spread throughout the Kandyan provinces and claimed, as Buddhists, a share in the management of Kandyan temporalities. The Kandyans, on the other hand, viewing penetration of their country by Low Country Sinhalese with dislike, remembered that these folk aided the Portuguese, the Dutch and the British in their several attacks on the Kandyan kingdom. Therefore they regarded any system of government that placed the supreme power in the hands of a majority with acute apprehension. These feelings were in some degree shared by the Ceylonese Tamils, though in their case it was they who invaded the country occupied by the Low Country Sinhalese. The Burghers were still more apprehensive; while the Europeans, who represented huge financial interests, alike in the world of commerce and in agricultural enterprise, were only 0.18% of the total population of the island.

The Low Country Sinhalese and Tamils formed in 1919 the Ceylon National Congress, but the latter withdrew in 1921 because, fearing Sinhalese predominance, they insisted that any change in the constitution should make provision for communal electorates. Meanwhile, in 1920 the composition of the legislative council was altered to 14 official and 23 unofficial members, and by another change in 1924 that body comprised 36 unofficial members (3 of whom were Europeans and the majority of whom were elected) and 12 official. At the same time three unofficial Ceylonese (two Sinhalese and one Tamil) and one European had been added to the executive council. Responsibility for the good administration of the island continued, none the less, to be vested solely in the governor, who was unable to discharge it save by the good will of the unofficial majority in the legislative council or by the exercise of his power of veto, which could easily be countered by a refusal to vote supply. Because of the resulting impasse, the working of the constitution was investigated during 1927–28 by the Donoughmore commission, and as outcome of that body's recommendations a new constitution came into force in 1931. Both the legislative and the executive councils were dissolved, and their place was taken by a state council having legislative and also executive functions. The new council consisted of 5 official members, 50 elected members and not more than 8 members nominated by the governor. The three official members ex officio were the chief secretary, legal secretary and financial secretary (formerly known, respectively, as the colonial secretary, attorney general and treasurer); while they could take part in debates they could not vote, and thus there was no longer an official minority. All elected members were elected on a territorial basis (the franchise being very wide), communal representation being abolished. The members of a new council proceeded by secret ballot to divide their total number (excluding the three officials, known as officers of state) into seven executive committees to administer seven of the ten groups into which the government departments were divided; each of the remaining three groups was supervised by an officer of state. Each executive committee elected a chairman, and these seven chairmen, termed ministers, and the three officers of state constituted a board of ministers; the three officials, who had no vote, served in an advisory capacity, the most important function of the board being the preparation of the annual estimates of revenue and expenditure.

In World War II it became necessary for Ceylon not only to grow many of the foodstuffs hitherto imported but vastly to increase its exports. As a producer of tea it ranked second only to India, and after Japanese occupation of the Malayan territories the island became the British empire's principal source of plantation rubber. In 1942 Ceylon was placed under the control of a British admiral, who left administration to the civil authorities until such time as the threat of Japanese attack might compel him to intervene. The British cabinet undertook to grant the colony full responsible internal government after conclusion of hostilities. The Soulbury commission of 1944–45 recommended further constitutional advance, and in May 1946 a new constitution was promulgated under which the executive committees of the Donoughmore constitution were replaced by cabinet government under the leadership of a prime minister. Agitation for full dominion status continued and resulted in the Ceylon Independence act of 1947. On Feb. 4, 1948, Ceylon became a dominion of the British Commonwealth. Don Stephen Senanayake had become prime minister in Sept. 1947 and continued as such until his death on March 22, 1952. He was succeeded by his son, Dudley Senanayake, who however resigned because of ill-health on Oct. 12, 1953, when Sir John Kotelawala succeeded him. On July 17, 1954, in succession to Lord Soulbury, Sir Oliver Goonetilleke became the first Ceylonese governor general.

(W. B. Pn.; C. C. D.)

In the mid-1950s Ceylon's external policy appeared to be shaped by a more-or-less positive anticommunism, in contrast with India's "noninvolvement"; by a sympathy toward the west somewhat greater than that shown by her neighbours; and by a certain apprehension of Indian domination. On Jan. 10, 1955, however, the resolutions committee of the government parliamentary group recommended that Ceylon should become a republic in May 1956.

SOCIAL AND ECONOMIC CONDITIONS

People.—The population of Ceylon at the time of the 1953 census was 8,098,637. Ceylon nationals as a whole are known as Ceylonese, a national name including not only the two principal groups (*i.e.*, Sinhalese and Ceylon Tamils) but also Ceylon Moors, who are the descendants of seafaring Arab merchants; Malays, the remnant of the Ceylon Malay regiments; Burghers, descendants of the Dutch; Eurasians; a few Portuguese; and a small number of naturalized Europeans, Indians and other nationalities. The Sinhalese themselves are of two main types, Low Country Sinhalese, who inhabit the plains, and Kandyans from the mountains. The Veddas or aboriginals are almost extinct as a pure race, but there are a number of half Veddas and quarter Veddas, intermixed with Sinhalese. The numerical strength of the various groups in Ceylon in 1953 is given in the table.

Group	Number	Group	Number
Low Country Sinhalese	3,464,126	Other Ceylonese*	20,678
Kandyan Sinhalese	2,157,206	Indians†	984,527
Ceylon Tamils	908,705	Pakistanis	5,749
Ceylon Moors	468,146	Europeans	5,886
Burghers	43,916	Other non-Ceylonese	11,162
Malays	28,736		

*Incl. Veddas (2,361 in 1946), Eurasians and naturalized Europeans and Indians.
†Mainly Tamils.

Towns.—For administration Ceylon is divided into nine provinces, with the most populous area in the west, around the capital, Colombo (423,481 in 1953), where the port handles 2,000,000 tons of cargo a year. Colombo harbour is artificially constructed by a concrete breakwater enclosing the roadstead. It was being modernized in the 1950s, and Queen Elizabeth II opened the first alongside quay when her ship the "Gothic" berthed there in 1954. The business quarter is close to the harbour in the areas occupied by the ancient fort, of which few traces except the name remain, and in the adjoining *pettah*, or bazaar. The wealthier residential sector is in the part of the town used by the Dutch as cinnamon gardens and is still known by that name.

The next largest cities are Jaffna (77,218 in 1953), in the Northern (Tamil) province, with a small port, and Dehiwala-Mt. Lavinia (80,086), on the fringe of Colombo. Then come Kandy (57,539), the capital of the Central province, famous for the Temple of the Tooth, and Moratuwa (58,160) and Kotte (53,862), both in the Western province. Trincomalee (28,236) is a naval base with one of the finest and largest natural land-

ocked harbours in the world. Galle (55,874), in the south, is a small natural harbour for ships of the freighter class, which, until overshadowed by the building of Colombo harbour at the end of the 19th century, was the main port of Ceylon.

Religion.—The Sinhalese are mainly Buddhists, both in religion and culture, and the Tamils are principally Hindus, with a culture akin to that of India. Moors and Malays are Moslems; with their exception a considerable proportion of all groups are Christians. Distribution of religions in 1953 was as follows: Buddhists 5,217,143; Hindus 1,614,004; Christians 714,874; Moslems 541,812. Religion plays a large part in Ceylonese life; the public holidays, 22 in all, are based on festivals, and pilgrimages feature prominently both in business and pleasure. The most famous pilgrimage is the ascent of Adam's Peak (*q.v.*), which takes place in March and April during which months the peak can be clearly seen from the sea to the southwest. This periodical distant and mysterious view of the mountain, in the centuries before accurate surveys of its height and position had been made, caused it to become an object of awe and legend to passing mariners. At sunrise the huge shadow of the mountain, thrown upon the mist in the valleys, can be seen from the summit, with its tip on the coast 60 mi. to the west, one of the most impressive sights in the world.

Another goal of pilgrims and tourists is the Temple of the Tooth in Kandy, wherein is enshrined the Sacred Tooth relic of the Lord Buddha. The Perahera, or annual torchlit temple procession, in which 100 gorgeously caparisoned elephants and hundreds of dancers take part, draws thousands of devotees and sightseers.

At Anuradhapura is the famous 2,000-year-old Bo tree, an offshoot of the tree under which Buddha meditated. This tree has the oldest authenticated history of any tree in the world.

Education.—Education was made free in 1945. It is based on the English system, from the village primary school through junior, senior and central schools to the university; the last is located on a site of great beauty near the famous botanical gardens at Peradeniya outside Kandy. Most villages have their own schools, either in the village itself or within a mile or two of it, and 57.8% of the population is literate, a high percentage compared with other Asian countries. The main languages are Sinhalese and Tamil, but 6.3% of the people can read and write English, while a much larger proportion can speak it.

Constitution.—Under the constitution, framed by the Soulbury commission and promulgated in 1946, there was established a house of representatives consisting of 101 members, 95 elected by universal franchise, including women, and a maximum of 6 nominated by the governor general if he is satisfied that any important interest is not otherwise represented. There is also an upper house or senate consisting of 30 members, of whom 15 are elected by the house of representatives and 15 appointed by the governor general. A number of ministers, headed by the prime minister, form the cabinet. Labour legislation provides for compulsory employment of a percentage of Ceylonese labour, workmen's compensation, maternity benefits and wage boards for several trades. Trade unionism strengthened after independence.

Agriculture.—The principal occupation of the inhabitants of Ceylon is agriculture. The most important crops are rice, for local consumption only; coconuts for local consumption and export of the oil; tea, mainly for export, although the large home demand is also met; and rubber, entirely for export. Other crops are cacao, cinnamon, cardamom, citronella, tobacco, pepper, palmyra, areca nuts and oil seeds such as sesame. Vegetables for local use are grown in profusion, and English varieties of vegetables grow well on the hills.

Rice, known as paddy before it is milled, is grown by Ceylonese on lands supplied with water through a large and efficient irrigation system of extensive artificial reservoirs or "tanks," originally built by the Sinhalese kings many centuries ago and restored by the British government. Except in government farms and in the agricultural "colonies" organized below the restored tanks, agricultural methods are still primitive, and fields are cultivated with an old-fashioned plow drawn by buffaloes. Mechanization is handicapped by the small size of the individual rice fields and the difficulty of reaching them with motor vehicles, but modern techniques such as transplating are practised.

The coconut tree is, next to rice, the most valuable crop, providing food, drink, oil for cooking and burning, rope, cattle food, timber and thatch, while all nuts not required for internal use find a lucrative market abroad in the form of copra and oil. About 1,800,000,000 nuts are produced annually on about 1,000,000 ac. of which more than four-fifths consists of village smallholdings and gardens.

Tea is grown mainly in the hills, on estates opened by British companies after the failure of the coffee crop, due to a pest in the 1870s. The annual export of tea from Ceylon is more than 300,000,000 lb. The majority of the labourers on tea estates are Tamils from India, but every year a larger number of Ceylonese are taking to the work and replacing the immigrants.

Rubber, introduced into Ceylon from South America in 1876, is grown principally on estates in the low country, but there are a number of village smallholdings. The annual export from Ceylon is about 220,000,000 lb.

Industry.—Ceylon is so largely agricultural that industry has developed slowly, being confined to a hydroelectric scheme, rice milling, coconut oil production and goods manufactured from other coconut oil products; but, with the coming of independence in 1947, industrial development became an important government policy. By 1952 the first stage of the hydroelectric scheme had been completed; in the north a cement factory had been set up and, in the south, a plywood factory was functioning, while factories for the manufacture of paper, vegetable oil products, glass, ceramics and DDT were completed in 1955. In May 1955 the government approved a six-year Rs. 2,100,000,000 (£161,000,000) economic development program.

Ceylon fisheries are the subject of active scientific development, and trawling is successfully conducted on the Wadge bank, off Cape Cormorin. Pearl fishing is a lucrative industry, but intermittent because of the vagaries of the oysters, which do not always select Ceylon waters for their residence.

The minerals of economic importance are plumbago or graphite, gem stones, ilmenite, iron, monazite, thorianite and mica. Plumbago is found in veins in the western part of the island, and gems, the most valuable of which are sapphires and other varieties of corundum, occur in river gravels, washed down from the southwest flank of the mountain mass. The gem industry, one of Ceylon's most romantic features, has been practised for centuries by digging pits 30 ft. deep, down to the gem gravel. This, when washed in a basket, reveals, beside sapphires, cinnamon rubies, cat's-eyes, zircons and most of the semiprecious stones. The principal area for gems is around Ratnapura, "Gem City."

There is a vast deposit of ilmenite on the shore at Pulmoddai, north of Trincomalee, and about 6,000,000 tons of good-quality surface iron are available in the southwest.

Transport.—Transport in Ceylon is well developed in the tea, rubber and coconut areas but, although there were about 14,000 mi. of motorable roads in 1955, the jungles of the north and east are sparsely traversed. The bullock cart is still universally used, but buses and lorries serve every part of the country, however isolated, and the railway (896 mi. in 1955, all 5 ft. 6 in. gauge, except 87 mi. 2 ft. 6 in. gauge) reaches all but the southeastern district with a frequent service. There is daily air service from Colombo to Jaffna, and to Trichinopoly in India.

Economy and Finance.—As the prosperity of Ceylon depends so greatly on its three main exportable agricultural products (*i.e.*, tea, rubber and coconuts), its economy, though prosperous, has to be regarded as precarious. Great efforts were therefore being made by the 1950s to establish a greater measure of self-sufficiency, by the construction of major social development works, such as the huge Gal-oya all-purpose dam, large irrigation works and new factories. Figures for foreign trade in 1954 were: imports Rs. 1,307,000,000; exports Rs. 1,809,000,000. The main sources of imports were: U.K. 21%; India 14%; Burma 9%; U.S. and Canada 4%. Main destinations of exports were: U.K. 29%; India and Burma 25%; U.S. and Canada 11%.

The unit rate of income tax in 1950 was 9½%, but only 1 person in every 260 at that time fell within the taxable scope. The

1950–51 budget showed revenue as Rs. 794,000,000 and expenditure as Rs. 704,000,000; the 1951–52 budget estimate was revenue Rs. 896,000,000 and expenditure Rs. 886,000,000. The monetary unit is the rupee with an exchange rate in 1952 of Rs. 13.13 to the pound sterling and Rs. 4.775 to $1 U.S.

(R. H. BT.; X.)

CÉZANNE, PAUL (1839–1906), French painter, was born at Aix, the ancient capital town of Provence, on Jan. 19, 1839. His father was a banker. Paul was educated at the *lycée* of the town, where he formed an intimate friendship with Émile Zola, the novelist. The two boys were both inspired by a love of the classics, particularly of Virgil, through whom, perhaps, Cézanne realized the beauty of his native country. Both decided to consecrate themselves to art. Zola settled down early to a literary career in Paris, but Cézanne endeavoured to comply with his father's wish that he should carry on the family bank. After two unsuccessful attempts the father allowed Paul to settle in Paris and attend the art school. He arrived there in 1863.

Cézanne became known as one of the most extreme of the young revolutionary painters, the bitterest in his denunciation of official art and of Ingres who, then in his old age, was regarded as the head of the reactionaries. In this way he became acquainted with the group of painters who encircled Manet, and who afterwards became known as the impressionists. But Cézanne's work in his early years shows no sign of this frequentation. At this period he was most influenced by Delacroix and by the Baroque painters whom Delacroix studied, by Rubens and Tintoretto. His ambition was to create grandiose compositions of a purely imaginative description, expressive of his own internal moods, using either violently dramatic themes—"Les Assassins," "L'Autopsie," "Lazare" —or lyrical motives—"Le Jugement de Paris," "Déjeuners sur l'herbe." He also painted a series of portraits in which dramatic and psychological effects were undertoned. In these the influence of Courbet is evident. They are painted with broad strokes, the palette-knife ploughing up and planting down an exceedingly thick and dense impasto. In all these early works the colour is reduced to a few simple notes in which black, white and earth reds and yellows predominate. The tension of Cézanne's imaginative life shews itself in the tumultuous vehemence of these early compositions. He trusts to his inner convictions with a blind and reckless courage which was unfortunately not supported by the gifts necessary to make such an imagery plausible, or to give verisimilitude to the contorted poses of his Tintorettesque nudes. His outlook on nature seems to have been confined for the most part to the search for motives of chiaroscuro suitable to the dramatic effects of his imaginative designs. He showed at this stage nothing of the curiosity about natural effects of colour which distinguished the impressionist group. He was, in fact, far more concerned with expressing the exaltation of his own feelings, inspired by literature or imaginative brooding, than with the phenomena of the visible world. A few still-lifes of this period show, however, how much greater his native endowment was in this direction than in the one he was consciously pursuing; but even in these the dramatic evocations of the thing seen are what chiefly interested him.

During the years 1872–73 a great change came over Cézanne. He spent the summers of these years at Auvers-sur-Oise in the company of Camille Pissarro, who was one of the impressionists. Pissarro was some years older than Cézanne and had already discovered his personal style and perfected a methodical and precise technique adapted to it. Cézanne, who had hitherto trusted to the inspiration of his imaginative ideas for his daring, but rather fortuitous technique, here for the first time underwent a methodical course of training. He learned for the first time to look on nature with a curious and contemplative gaze, and he learned a precise and methodical technical process, by which to record the results thus obtained. Above all, the whole world of "atmospheric" colour was thus revealed to him. Certain pictures painted by Cézanne in these years approximate very nearly to Pissarro's work, but they show Cézanne's greater power of organizing form, and the greater profundity of the conceptions which his contemplation of natural appearance provoked in his intensely passionate nature. For these years, then, Cézanne may be counted an impressionist.

But Cézanne's response to appearances gave him a notion of design more vigorously constructed, and evocative of far deeper feelings, than any that the impressionists envisaged. To them the weft of colour which nature revealed to their specialized visual sense was all that mattered; out of that each artist could choose unconsciously those harmonies which specially appealed to him. But Cézanne always believed in some underlying reality of a more permanent kind, more consonant with the deeper instincts of human nature. The impressionist vision was both too casual and too imperfectly organized for him. It missed part of the truth which the older masters had apprehended. Cézanne summed up his own attitude by saying that his ambition was to do Poussin over again after nature, *i.e.*, to incorporate into a clearly organized formal unity, like Poussin's, the vision of natural appearance as enriched by impressionist researches. From this point Cézanne's personal vision and his personal expression of it were established. Such changes as his style underwent in the succeeding decades were only gradual modifications of what he had established once for all. The essentials of that style were due, as we have seen, to the special use he made of the impressionist vision. They were based upon the most rigorous construction of the design by means of the interplay of clearly articulated planes. But the movement of these planes, their salience and recession, was interpreted quite as much by changes in local colour as by the definition of form by light and shade. A characteristic of Cézanne's completely realized manner is the extreme simplicity of the approach, the fact that objects are presented in full frontal aspect. In nearly all his portraits the sitter is placed nearly in the centre of the canvas, the head and body being seen nearly in full face. In the landscapes a similar treatment is found; objects are extended in planes parallel to the picture plane, and frequently the main mass will be centrally placed. Such extreme symmetrical simplicity of approach takes us back to the practice of the Italian Primitives. It is violently opposed to the principles of Baroque composition as followed by most of Cézanne's predecessors and by himself in his early period.

Such an exaggeratedly simple disposition would probably strike us as crude and uninteresting if it were not that within the volumes which he places before us in this elementary fashion, his analysis of changes of surface and plastic movement is pushed to an extraordinary degree, and this is accompanied by innumerable slight modulations of colour, so that the whole surface takes on something of the infinity of natural appearance. This practice he developed with ever-increasing power. In the '70s and early '80s, the almost laborious scrutiny of infinitesimal colour changes led him to load the canvas with repeated layers of colour, though without ever losing purity and intensity. Later on he was able to get the same multiplicity of surface with thinner layers of colour. Together with this he tended also to simplify the colour changes, adopting even a regular principle of colour sequences to express movements away from the highest relief of any given volume. All this was strictly in keeping with his philosophical conception of the aim of painting. In everything he did he sought a synthesis in which the most rigorously logical plastic structure should be combined with the utmost liveliness of surface; that is to say, he sought, without losing the infinitude of natural appearance, to give to it an intelligibility and a logical coherence which it lacks. This, no doubt, is more or less the problem of all painting; what distinguishes Cézanne is his endeavour to attain this synthesis when each of the opposite terms is at its highest pitch.

To the last decade of the 19th century belong some of his most celebrated works: the portrait of Geffroy, which is perhaps unequalled in modern art for the completeness of its realization, the complexity and assurance of its harmonies; several versions of a composition of men seated at a café table and playing cards, in

which the primitive simplicity of the arrangement gives an elemental grandeur to the forms; and a series of landscapes in which the pyramidal mass of Mt. Ste. Victoire dominates the design. Even to the end of his life, Cézanne always cherished the hope of creating imaginative and "poetical" designs of nude figures in landscape, after the manner of some of Giorgione's and Titian's pictures. But in this he was hampered by his extreme reluctance to draw from the nude model, and most of these grandiose attempts remain failures.

At the very end of his life there seems to have been a kind of recrudescence in Cézanne of the romantic tendencies of his youth. His paintings became richer, more intense and vivid in colour, more agitated in rhythm, more vehement in accent; they also departed more and more from the careful analysis of natural appearance of the middle period, as though his long apprenticeship to nature had ceased and he felt free to follow unhesitatingly his instinctive feeling. The middle and end of Cézanne's life was passed in great seclusion at Aix, with occasional visits to Paris. In the 1880s and 1890s his very name had become almost unknown in the larger art circles of Paris, though he never lacked a few enthusiastic admirers. Gradually his fame began to circulate among the more intelligent artists, and in 1904 a retrospective exhibition of his works in the Autumn Salon revealed to the public the existence of this almost unknown genius. It was the only foretaste of his posthumous fame which he experienced. He died Oct. 23, 1906.

C.G.S. SYSTEM, a system of units which takes as a basis the centimetre, the gram and the second. (*See* PHYSICAL UNITS and ABSOLUTE UNITS.)

CHABAZITE, a mineral species belonging to the group of zeolites. It occurs as white to flesh-red crystals which vary from transparent to translucent and have a vitreous lustre. The crystals are rhombohedral, and the predominating form is often a rhombohedron with interfacial angles of 85° 14′; they therefore closely resemble cubes in appearance, and the mineral was in fact early (in 1772) described as a cubic zeolite. A characteristic feature is the twinning, the crystals being in many cases interpenetration twins with the corners of small crystals in twinned position projecting from the faces of the main crystal. A flat lenticular form of crystal is also common, this variety being known as phacolite (from *φακός*, a lentil). The hardness is 4½, and the specific gravity 2.08–2.16.

TWINNED CRYSTAL OF CHABAZITE
Interpenetrating rhombohedra (nearly cubic in form) are especially characteristic of this mineral

Chemically, chabazite is a complex hydrated calcium and sodium silicate. The composition is, however, variable, and is best expressed as an isomorphous mixture of the molecules $(Ca,Na_2)Al_2Si_4O_{12}+4H_2O$ and $(Ca,Na_2)Al_2(Si_3O_8)_2+8H_2O$, which are analogous to the feldspars. Most analyses correspond with a formula midway between these extremes, namely $(Ca,Na_2)Al_2(SiO_3)_4+6H_2O$. Chabazite occurs with other zeolites in the amygdaloidal cavities of basaltic rocks; occasionally it has been found in gneisses and schists. Gmelinite is another species of zeolite which may be mentioned here, since it is closely related to chabazite. It forms large flesh-red crystals usually of hexagonal habit, and was early known as soda-chabazite, it having the composition of chabazite, but with sodium predominating over calcium $(Na_2.Ca)\ Al_2(SiO_3)_4+6H_2O$. (L. J. S.)

CHABLIS, a town of north central France, in the department of Yonne, on the left bank of the Serein, 14 mi. E. of Auxerre by road. Pop. (1946) 1,786. Its church of St. Martin belongs to the end of the 12th century. The town gives its name to a well-known white wine (*see* BURGUNDY WINES).

CHABOT, FRANÇOIS (1757–1794), French revolutionary, born at St. Geniez, near Aveyron, had been a Franciscan friar before the Revolution, and after the civil constitution of the clergy continued to act as "constitutional" priest. Then he was elected to the legislative assembly, sitting at the extreme left, and forming with C. Bazire and Merlin de Thionville the "Cordelier trio." Re-elected to the convention he voted for the death of Louis XVI, and opposed the proposal to prosecute the authors of the massacre of September. Compromised in the falsification of a decree suppressing the India company and in a plot to bribe certain members of the convention, especially Fabre d'Eglantine and C. Bazire, he was condemned by the Revolutionary tribunal and executed on April 5, 1794.

See *François Chabot . . . à ses concitoyens, . . . pluviose, an II, Mémoire apologetique, . . .* etc. ed. A. Mathiez (1914); J. M. J. A. de Bonald, *François Chabot, membre de la Convention* (1908).

CHABOT, PHILIPPE DE, SEIGNEUR DE BRION, COUNT OF CHARNY AND BUZANÇAIS (1492?–1543), admiral of France. The Chabot family was one of the oldest and most powerful in Poitou. Philippe was a cadet of the Jarnac branch. He was a companion of Francis I as a child, and on that king's accession received many honours and estates. After the battle of Pavia he was made admiral of France and governor of Burgundy (1526), and shared with Anne de Montmorency the direction of affairs. He was at the height of his power in 1535, and commanded the army for the invasion of the states of the duke of Savoy; but in the campaigns of 1536 and 1537 he was eclipsed by Montmorency, and his influence began to wane. He was accused by his enemies of peculation, and condemned on Feb. 10, 1541, to a fine of 1,500,000 livres, to banishment, and to the confiscation of his estates. Through the good offices of Madam d'Étampes he obtained the king's pardon (March 1541) and was reinstated, while Montmorency was disgraced. He died on June 1, 1543.

CHABRIAS (4th century B.C.), Athenian general. In 388 B.C. he defeated the Spartans of Aegina and commanded the fleet sent to assist Evagoras, king of Cyprus, against the Persians. In 378, when Athens joined Thebes against Sparta, he defeated Agesilaus near Thebes. On this occasion he invented a manœuvre, which consisted in receiving a charge on the left knee, with shields resting on the ground and spears pointed against the enemy. In 376 he defeated the Spartan fleet off Naxos, but, when he might have destroyed the enemy, remembering Arginusae (*q.v.*), he delayed to pick up his dead. Later, when the Athenians joined the Spartans, he repulsed Epaminondas before Corinth. In 366, together with Callistratus, he was accused of treachery in advising the surrender of Oropus to the Thebans. He was acquitted, and soon after he accepted a command under Tachos, king of Egypt, who had revolted against Persia. On the outbreak of the Social War (357) he joined Chares in the command of the Athenian fleet. He lost his life in an attack on the island of Chios, probably in the same year. *See* also DELIAN LEAGUE.

See Cornelius Nepos, *Chabrias;* Xenophon, *Hellenica,* v, 1–4; Diod. Sic. xv, 29–34; *Cambridge Ancient History,* vol. vi (1927) chapters iii, vi and viii (with useful bibliography).

CHABRIER, ALEXIS EMMANUEL (1841–1894), French composer, was born at Ambert, Puy de Dôme, on Jan. 18, 1841, and first attracted general attention in 1883 by his brilliant orchestral rhapsody entitled *España,* the themes of which he had jotted down when travelling in Spain. His opera *Gwendoline*, produced at Brussels on April 10, 1886, was successful too and still more so its successor, of a lighter type, *Le Roi malgré lui,* which was brought out in Paris at the Opéra Comique.

CHACMA, the Cape baboon, *Papio comatus,* inhabiting the mountains of South Africa as far north as the Zambezi. The size of an English mastiff, this powerful baboon is blackish-gray in colour with a tinge of green due to the yellow rings on the hairs. Unlike most of its tribe, it is a good climber. It is destructive to crops.

CHACO, a territory of northern Argentina, part of a large district known as the Gran Chaco, bounded north by the territory of Formosa, east by Paraguay and Corrientes, south by Santa Fé and west by Santiago del Estero and Salta. It became the province of President Perón in 1950, with a constitution of a type not previously known in Argentina—the corporate state. It is rich in timber (more than 70 varieties of hardwoods), and sugar,

cotton and other products are profitably cultivated on its plains. The capital is Resistencia. The Bermejo river forms its northern boundary and the Paraguay and Paraná rivers its eastern. Pop. (1947) 430,555; area, 38,468 sq.mi. (C. E. Mc.)

Northern Chaco had long been the subject of dispute between Bolivia and Paraguay. Armed clashes over its possession began in 1928 and gradually developed into open war. All efforts of other states and the League of Nations to mediate were unavailing And the belligerents continued their bloody struggle in spite of a seeming bankruptcy on both sides. Paraguay, on the whole, proved the more successful in arms. Finally a truce was arranged on June 12, 1935. Under the arbitral award of 1938, Paraguay received most of the disputed area.

CHACO CANYON, a tract of about 20,000 ac. in north-western New Mexico, U.S.A., set apart in 1907 as a national monument. It contains the most remarkable architectural remains of prehistoric North America and has yielded a rich collection of objects illustrative of a vanished civilization. The buildings, which sometimes attained a height of at least four storys, show a variety of methods in stone construction. Several are of enormous size, Pueblo Bonito, the largest, measuring 667 ft. by 315 ft.; a wall still standing rises to 48 feet. This building, like most of the others, constituted a veritable village and contained 800 rooms and 32 *kivas,* or large ceremonial halls. Chetro-Kettle and Peñasco Blanco are similar structures, while other ruins show that the private house also was in use.

CHACONNE, a slow dance, introduced into Spain by the Moors now obsolete. It resembled the Passacaglia. The word is used also of the music composed for this dance—a slow, stately movement in ¾ time. Such a movement was often introduced into a sonata, and formed the conventional finale to an opera or ballet until the time of Gluck. The most famous of all chaconnes is that of Bach for violin unaccompanied—a colossal example which is generally played as an independent piece, though it is actually a movement in one of his violin sonatas (No. 4).

CHAD (CEADDA), **SAINT** (d. 672), brother of Cedd, whom he succeeded as abbot at Lastingham, was consecrated bishop of the Northumbrians by Wine, the West Saxon bishop, at the request of Oswy in 664. On the return of Wilfrid from France, where he had been sent to be consecrated to the same see, a dispute arose, which was settled by Theodore in favour of Wilfrid. Chad thereupon retired to Lastingham, whence with the permission of Oswy he was summoned by Wulfhere of Mercia to succeed his bishop Jaruman (d. 667). Chad built a monastery at Barrow in Lincolnshire and fixed his see at Lichfield.

See Bede's *Hist. Eccl.;* Eddius, *Vita Wilfridi,* xiv., xv., ed. J. Raine, Rolls series (1879).

CHAD, a lake of northern Central Africa lying between 12° 50′ and 14° 10′ N. and 13° and 15° E. It lies about 800 ft. above the sea in the borderland between the Sudan and the Sahara. The lake has greatly shrunken since it was first seen by Europeans; this is attributed to the progressive desiccation of the region. Thus a town which in 1850 was on the southern margin of the lake was in 1905 over 20m. from it. But as the west shore is perfectly flat, a slight rise in the water causes the inundation of a considerable area, a fact to be remembered in considering the estimates made as to the size of the lake. In any case the Chad is but the remnant of what in recent geological times was a very much larger sheet of water spreading south, north east and east of its present limits. A considerable area lying to the north-east is below the level of the lake. Around the north-west and north shores is a continuous chain of gently sloping sand-hills covered with bush. In the east, the country of Kanem, the desiccation has been most marked. Along this coast is a continuous chain of islands running from north-west to south-east. They are generally low, being composed of sand and clay, and lie from 5 to 20m. from the shore, which throughout its eastern side nowhere faces open water. Two principal groups of islands are distinguished, the Kuri archipelago in the south, and the Buduma in the north. The inhabitants of Buduma were noted pirates until reduced to order by the French. The coastline is, in general, undefined and marshy, and broken into numerous bays and peninsulas. It is also, especially on the east, lined by lagoons which communicate with the lake by intricate channels, while across the middle of the lake are numerous mud-banks, marshes, islands and dense growths of aqueous plants. Another stretch of marsh usually cuts off the northernmost part of the lake from the central sections. The open water varies in depth from 3ft. in the north-west to over 20 in the south. Fed by the Shari and other rivers, the lake has no outlet. The flood water brought down by the Shari in December and January causes the lake to rise to a maximum of 24ft., the water spreading over low-lying ground, left dry again in May or June. But after several seasons of heavy rainfall the waters have remained for years beyond their low-water level. Nevertheless the loss by evaporation (estimated in the dry season to be 10in. a month) and percolation is believed to exceed the amount of water received.

The southern basin of Chad is described under the Shari, which empties its waters into the lake about the middle of the southern shore, forming a delta of considerable extent. Beyond the south-east corner of the lake is a channel or depression known as the Soro or Bahr-el-Ghazal (not to be confounded with the Bahr-el-Ghazal affluent of the Nile). This channel goes north-north-east and some 250m. from the lake reaches its lowest point, 500ft. below Chad, in what is known as the Kiri lake (now dry). The remarkable levels led to the supposition of a connection between the basins of the Chad and the Nile. The French explorer, Jean Tilho, in his 1912–17 expedition showed that this was not the case and that the Chad is a closed basin. The Soro depression continues north-east some distance beyond Kiri. Then in the valleys between the Tibesti and Ennedi mountains the ground gradually rises and forms the watershed between Nile and Chad. In this direction, however, Chad at one time extended to the foothills of Tibesti and Borku. Besides the Shari, the Yedseram and Ulge enter the Chad on the south. The only other important affluent of the Chad is the Waube or Yo (otherwise the Komadugu Yobe), which rises near Kano, and flowing eastward enters the lake on its western side 40m. N. of Kuka.

Lake Chad is supposed to have been known by report to Ptolemy, and is identified by some writers with the Kura lake of the middle ages. It was first seen by white men in 1823 when it was reached by way of Tripoli by Walter Oudney, Hugh Clapperton and Dixon Denham. By them the lake was named Waterloo. In 1850 James Richardson, accompanied by Heinrich Barth and Adolf Overweg, reached the lake, also via Tripoli, and Overweg was the first European to navigate its waters (1851). The lake was visited by Eduard Vogel (1855) and by Gustav Nachtigal (1870), the last-named investigating its hydrography in some detail. Owing to an exaggerated belief in its economic importance there was during the partition of Africa a "race" for Lake Chad; in 1890–93 its shores were divided by treaty between Great Britain, France and Germany. The first of these nations to make good its footing in the region was France. A small steamer, brought from the Congo by Emile Gentil, was in 1897 launched on the Shari, and, reaching the Chad, navigated the southern part of the lake. A British force under Col. T. L. N. Morland visited the western or Bornu side of the lake at the beginning of 1902, and in May of the same year the Germans reached Chad from the Cameroons. In 1902–03 French officers under Col. Destenave made detailed surveys of the south-eastern and eastern shores and the adjacent islands. In 1905 Boyd Alexander, a British officer, found that the lake then contained few stretches of open water. Later travellers found a good deal of open water; the extent of the water varying from year to year. One of the ancient trade routes across the Sahara from Tripoli to Kuka in Bornu strikes the lake at its north-west corner, but this has lost much of its former importance. As one of the results of the World War, that part of the lake region which was German passed (1919) under French mandate.

See the works of Denham, Clapperton, Barth and Nachtigal cited in the biographical notices: Jean Tilho in *La Géographie* (March, 1906); and the *Geog. Journal,* vol. lvi. CHADDERTON, an urban district of Lancashire, England on the river Irk, 1 mi. W. of Oldham. Pop. (est. 1938), 30,270. Area, 4.71 sq.mi. It is a textile town, with some metalworking.

CHADERTON, LAURENCE (?1536–1640), Puritan divine, was born at Lees Hall, Oldham, Lancashire, was educated at Christ's college, Cambridge, and on the foundation of Emmanuel college in 1584, Sir Walter Mildmay, the founder, chose Chaderton for the first master. Chaderton was one of the four divines appointed to represent the Puritans at the Hampton Court conference; and he was also one of the translators of the Bible. He provided for 12 fellows and more than 40 scholars in Emmanuel college. Fearing that he might have a successor who held Arminian doctrines, he resigned the mastership in favour of John Preston. He died on Nov. 13, 1640, at the age of about 103, preserving his bodily and mental faculties to the end.

Chaderton published a sermon preached at St. Paul's Cross about 1580, and a treatise *On Justification* at Leyden. Other theological works remain in manuscript.

CHADRON, a city of northwestern Nebraska, U.S., in the heart of the Pine Ridge country, at an altitude of 3,370 ft.; the county seat of Dawes county. It is on federal highway 20 and the Chicago and North Western railway. The population was 4,645 in 1950, and was 4,262 in 1940 by the federal census. Pine-clad buttes give the city a delightful setting, and the Black hills of South Dakota are visible in the distance.

Chadron is the trade centre of a fine cattle and farming region, a division point on the railway, which maintains a roundhouse and machine shops there, and the seat of a state teachers' college (established 1911), which has an enrolment of more than 1,200. Four miles west is an emergency landing field and a weather station. The Pine Ridge Indian reservation (in South Dakota) is 35 mi. north, and 8 mi. south is a state park. Chadron was settled in 1885 and incorporated in 1886.

CHADWICK, SIR EDWIN (1800–1890), English sanitary reformer, was born at Longsight, near Manchester, Jan. 24, 1800, and was educated for the bar. His essays in the *Westminster Review* introduced him to the notice of Jeremy Bentham, who engaged him as a literary assistant. In 1832 he was employed by the royal commission on the poor laws as an investigator, and in 1833 he was made a full member of that body. In conjunction with Nassau W. Senior he drafted the report of 1834 which procured the passing of the new poor law. His special contribution was the institution of the union as the area of administration. In 1834 he was appointed secretary to the poor law commissioners. His relations with his official chiefs became much strained, and the disagreement led among other causes, to the dissolution of the poor law commission in 1846. Chadwick's chief contribution to political controversy was his constant advocacy of entrusting certain departments of local affairs to trained and selected experts, instead of to representatives elected on the principle of local self-government. His report on "The Sanitary Condition of the Labouring Population" (1842) is a valuable historical document. He was a commissioner of the board of health for improving the water supply, drainage and cleansing of great towns, from its establishment in 1848 to its abolition in 1854. He was made K.C.B. in 1889. He died at East Sheen, Surrey, on July 6, 1890.

See Haven Emerson, "Public Health Diagnosis," *Journal of Preventive Medicine,* vol. i, pp. 401–427 (1927).

CHADWICK, SIR JAMES (1891–), British physicist, was born in Manchester on Oct. 20, 1891. He was educated at the universities of Manchester and Cambridge, and at Charlottenburg institution in Berlin, where he studied under Hans Geiger. In 1921 he was made a fellow of Gonville and Caius college, Cambridge, and two years later became assistant director of radioactive research at the Cavendish laboratory, Cambridge. Chadwick received the 1935 Nobel award in physics for his discovery of the neutron. He was knighted in 1945 and became master of Gonville and Caius college in 1948. His writings include *Radiations from Radioactive Substances* (with E. Rutherford and C. D. Ellis [1930]).

CHAEREMON, Athenian dramatist of the first half of the 4th century B.C. Aristotle (*Rhetoric,* iii. 12) says his works were intended for reading, not for representation. According to Suidas, he wrote comedy as well as tragedy, and the title of his *Achilles, Slayer of Thersites* suggests that it was a satyric drama. His *Centaurus* is described by Aristotle (*Poet.* i. 12) as a rhapsody in all kinds of metres. The fragments of Chaeremon are correct in form and have an easy rhythm, but are marred by a florid style. It is not agreed whether he is the author of three epigrams in the Greek Anthology (Palatine vii. 469, 720, 721) which bear his name.

See H. Bartsch, *De Chaeremone Poëta tragico* (1843); fragments in A. Nauck, *Fragmenta Tragicorum Graecorum.*

CHAEREMON, of Alexandria (1st century A.D.) Stoic philosopher and grammarian. He was superintendent of part of the Alexandrian library and belonged to the higher ranks of the priesthood. In A.D. 49 he was summoned to Rome, with Alexander of Aegae, to become tutor to the youthful Nero. He was the author of a *History of Egypt;* of works on *Comets, Egyptian Astrology,* and *Hieroglyphics;* and of a treatise on *Expletive Conjunctions.* Chaeremon was the chief of the party which explained the Egyptian religious system as an allegory of the worship of nature. He can hardly be identical with the Chaeremon who accompanied (*c.* 26 B.C.; Strabo xvii. p. 806) Aelius Gallus praefect of Egypt, on a journey into the interior.

Fragments in C. Müller, *Fragmenta Historicorum Graecorum,* ii 495–499.

CHAERONEIA, an ancient town of Boeotia, about 7m W. of Orchomenus. It may be the Homeric Arne. The site is partly occupied by the village of Kapraena; the ancient citadel was known as the Petrachus, and there is a theatre cut in the rock. Until the 4th century B.C. it was a dependency of Orchomenus. Its importance lay in its strategic position, the last serious obstacle to an invader of central Greece from the north. Two great battles were fought on this site in antiquity. In 338 B.C. Philip II. of Macedon defeated a confederation of Greek States (*see* below). In 86 B.C. the Roman general L. Cornelius Sulla defeated the army of Mithridates VI., king of Pontus, near Chaeroneia. Numerical superiority was neutralized by judicious choice of ground and the steadiness of the legionaries. Chaeroneia was the birthplace of Plutarch, who returned to his native town in old age, and was long held in honour. Pausanias (ix. 40) mentions the divine honours accorded at Chaeroneia to the sceptre of Agamemnon. (*Iliad,* ii. 101.) A colossal seated lion a little to the south-east of the site marks the grave of the Boeotians who fell fighting against Philip. This lion was found broken to pieces; the tradition that it was blown up by Odysseus Androutsos is incorrect (*see* Murray, *Handbook for Greece,* ed. 5. 1884, p. 409). It was re-erected in 1905.

CHAERONEIA, BATTLE OF, 338 B.C. This is of great historial importance as the victory by which Philip II (*q.v.*) definitely established the Macedonian supremacy in Greece. In military history, however, too little is known of its details to give it marked significance. Philip's path into Boeotia was barred by the allied Athenians and Thebans both at the western route from Cytinium to Amphissa and the eastern pass of Parapotamii from Elateia to Chaeroneia. Philip first placed himself at Elateia; then, by a ruse of withdrawal, put the defenders of the western route still more off their guard and, moving from Cytinium by night, debouched into western Boeotia at Amphissa. He was thus on the rear of but at a distance from the defenders of the eastern pass, who thereupon fell back from Parapotamii. But instead of passing eastwards through hilly country which would have aided the resistance, he switched his army back to Elateia, moved unopposed through the pass of Parapotamii and descended upon the enemy's main army at Chaeroneia. Philip placed his 18-year old son, Alexander, in charge of the left wing, where his best troops

faced the redoubtable Thebans and after a bitter struggle gained the upper hand. Meanwhile he had retired his right wing elastically before the onset of the Athenians until he had drawn them on to low ground while he had retired on to a rising slope. Then, suddenly he launched a counterstroke and disrupted the Athenians. Both the victorious Macedonian wings now converged inwards upon the allied centre and crushed it between them. With the overthrow of the Theban army and the annihilation of the famous "Sacred Band" the sceptre of military as well as of political supremacy passed to the "new model" army of Macedonia that Philip had created. (*See* also MANTINEIA; GRANICUS, BATTLE OF THE; ALEXANDER III.)

CHAETOGNATHA, a small group of transparent and for the most part pelagic organisms, whose position is very isolated. There are eight genera and 38 species; the best-known genus is *Sagitta* with 27 species. These animals exist in extraordinary quantities, so that under certain conditions the surface of the sea seems almost stiff with the incredible multitude of organisms which pervade it. Rough seas cause them to drop into deeper water. Deep-sea forms also occur, but the group is essentially pelagic. The Chaetognatha form part of the diet of pelagic fishes. They are very voracious, readily devouring herring fry as big as themselves.

As a rule the body is 1 to 3 cm. in length, though some species are larger, by 4 or 5 mm. in breadth, and is shaped something like a torpedo with side flanges and a slightly swollen, rounded head. It can be divided into three regions—(i.) head, (ii.) trunk, and (iii.) tail, separated from one another by two transverse septa. The almost spherical head is covered by a hood which can be retracted; it bears upon its side a number of sickle-shaped, chitinous hooks and rows of low spines. A pair of eyes lie dorsally. The trunk contains a spacious body-cavity filled during the breeding season by the swollen ovaries, and the same is true of the tail, substituting testes for ovaries.

CHAETOGNATHA, "ARROW-WORM," A GROUP OF TRANSPARENT ORGANISMS WHICH EXIST IN GREAT QUANTITIES NEAR THE SURFACE OF THE OPEN SEA

The skin consists of a transparent cuticle secreted by the underlying ectoderm; beneath this is a basement membrane; and then a layer of longitudinal muscle fibres which are limited inside by a layer of peritoneal cells. The muscles are striated and arranged in four quadrants. Along each side of the body stretches a horizontal fin and a similar flange surrounds the tail.

The mouth opens on to the ventral surface of the head. It leads into a straight alimentary canal whose walls consist of a layer of ciliated cells, ensheathed in a thin layer of peritoneal cells. There is no armature, and there are no glands, and the whole tract can be divided only into an oesophagus and an intestine. A median mesentery running dorso-ventrally supports the alimentary canal and is continued behind it into the tail, thus dividing the body cavity into two lateral halves.

There are no specialized circulatory, respiratory or excretory organs. The nervous system consists of a cerebral ganglion in the head, and a ventral ganglion in the trunk, with lateral commissures uniting these ganglia on each side. There is a minute but extensive nervous plexus all over the body.

Chaetognatha are hermaphrodite. The ovaries are attached to the side walls of the trunk region; between them and the body all lie the two oviducts whose inner and anterior end is closed, their outer ends opening one on each side of the anus, where the trunk joins the tail. This oviduct fits closely over a second duct, the receptaculum seminis, which the spermatozoa enter, passing through the walls and finally reaching the ripe ovum. Temporary oviducts are formed at each oviposition. A number of ova ripen simultaneously. The two testes lie in the tail and the spermatozoa pass out through short vasa deferentia with internal ciliated funnels.

With hardly an exception the transparent eggs are laid into the sea and float on its surface. The development is direct and there is no larval stage. As in some insects, the cells destined to form the reproductive organs are very early apparent.

The great bulk of the group is pelagic, as the transparent nature of all their tissues indicates. They move by flexing their bodies. The Chaetognatha appear to have no close relatives, and probably arose from the primitive *Procoelomate* stock in very ancient times. Recently Meek has attempted to show that they are related to the vertebrates.

(*See* also PLANKTON.)

See G. T. Burfield, "Sagitta" (*L.M.B.C Memoirs*, xxviii. (1927); Meek, *Proc. Zool. Soc.* (Lond. 1928).

CHAETOPODA, originally a zoological class, including all the Annelida (*q.v.*), except the Echiurida (*q.v.*). F. E. Beddard used the term to cover the classes Archiannelida, Polychaeta, Oligochaeta, Hirudinea (leeches) and Myzostomida. Parker and Haswell (*Textbook of Zoology*) use the term to include only the Polychaeta and Oligochaeta. The characteristic feature of Chaetopoda is the possession of bristles (*setae*). The term is now obsolete.

CHAFER, a word used in modern speech to distinguish the beetles of the family Scarabaeidae, and more especially those species which feed on leaves in the adult state. For the characters of the Scarabaeidae, *see* COLEOPTERA.

This family includes a large number of beetles, some of which feed on dung and others on vegetable tissues.

The cockchafers and their near allies belong to the subfamily Melolonthinae, and the rose-chafers to the Cetoniinae; in both the beetles eat leaves, and their grubs spend a long life underground devouring roots.

In Europe the Melolonthines that are usually noted as injurious are the two species of cockchafer (*Melolontha melolontha* and *M. hippocastani*), large heavy beetles with black pubescent prothorax, brown elytra and an elongated pointed tail-process; the summer-chafer (*Amphimallon solstitialis*), a smaller pale brown chafer.

In the United States, Melolonthines of the genus *Phyllophaga* (popularly known as "May beetles" or "June beetles") may do considerable damage to strawberries, corn (maize), wheat and grass crops.

The most important species is probably *Phyllophaga rugosa*, which frequently is very destructive to corn.

The larvae of the chafers are heavy, soft-skinned grubs, with hard brown heads provided with powerful mandibles, three pairs of well-developed legs, and a swollen abdomen. As they grow, they become strongly flexed towards the ventral surface, and lie curled up in their earthen cells, feeding on roots. The larval life lasts several years, and in hard frosts the grubs go deep down away from the surface.

Pupation takes place in the autumn, and though the perfect insect emerges from the cuticle very soon afterwards, it remains in its underground cell until the ensuing summer. After pairing, the female crawls down into the soil to lay her eggs. The grubs of chafers, when turned up by the plow, are greedily devoured by poultry, pigs and various wild birds.

CHAFF, the husks left after threshing grain (A.S. *ceaf*, allied to O.H.Ger. *cheva*, a husk or pod); also hay and straw chopped fine as food for cattle; hence, the worthless part of anything. The colloquial phrase, to chaff, meaning to make fun of a person, is derived from this word, or from "to chafe," meaning to irritate.

CHAFFARINAS or **ZAFFARINES,** a group of islands owned by Spain, 2½ mi. north of Cabo del Agua, in Morocco. Pop. *c.* 345, mainly soldiers of a garrison stationed there. The islands,

which were the *Tresinsulae* of the Romans and the *Zafrān* of the Arabs, were occupied by Spain in 1848. Construction of breakwaters between the islands of Isabella II and El Rey were undertaken; one dike was destroyed by storm in 1914. The largest island, Del Congreso, is rocky and hilly.

CHAFFCUTTER: *see* PROCESSING MACHINERY.

CHAFFEE, ADNA ROMANZA (1842–1914), United States soldier, born April 14, 1842, in Orwell, Ohio. He enlisted in the 6th cavalry regiment July 22, 1861, and was a member of that regiment for 25 years. The 6th cavalry was with the Army of the Potomac through most of the Civil War. Chaffee was commissioned 2nd lieutenant in May 1863, was wounded and taken prisoner at Gettysburg, refused to be paroled and was abandoned with other wounded. On Feb. 22, 1865, he was made 1st lieutenant. After the war the 6th cavalry was sent to Texas, and in 1867 Chaffee resigned, planning to enter private business. He was persuaded to change his mind, was restored to his rank, and served in the southwest until the Spanish-American War broke out, rising to the rank of lieutenant colonel. He served in the Spanish-American War, and at its conclusion was made chief of staff of the military governor of Cuba until May 1900. He became a colonel in May 1899. Chaffee commanded the U.S. troops in China during the Boxer uprising, and was military governor of the Philippine Islands July 1901–Sept. 1902. In 1904 he was promoted to lieutenant general and detailed as chief of staff. He retired Feb. 1, 1906, and died in Los Angeles, Calif., Nov. 1, 1914.

CHAFFINCH, a bird (*Fringilla coelebs*), belonging to the family Fringillidae (*see* FINCH), distinguished, in the male sex, by the deep grayish blue of its crown feathers, the yellowish green of its rump, two conspicuous bars of white on the wing coverts, and the reddish brown passing into vinous red of the throat and breast. The female is drab, but shows the same white markings as the male; the young males resemble the females until after the first autumn moult. The chaffinch breeds early, and its song may be heard in February. It builds its nest on trees and bushes, preferring those overgrown with lichens. The nest is composed of moss and wool, lined with grass and feathers. It lays four or five eggs of a pale bluish buff, streaked and spotted with purplish red. In spring the chaffinch is destructive to early flowers, and to young radishes and turnips; in summer it feeds on insects and their larvae, while in autumn and winter its food consists of grain and other seeds. On the continent of Europe the chaffinch is a favourite songbird. In winter chaffinches form small flocks, often composed solely of males. The continental chaffinch (*F. c. coelebs*) ranges generally over Europe to tree-limit in the north, wintering southward. The British chaffinch (*F. c. gengleri*) is a breeding resident. Allied races are found in northwest Africa, Canaries, Madeira and Azores. (G. F. Ss.)

CHAGRES, a village of the Republic of Panamá, on the Atlantic coast of the Isthmus, at the mouth of the Chagres river, and about 8 mi. W. of Colón. It has a harbour from 10 to 12 ft. deep, which is difficult to enter, however, on account of bars at its mouth. The port was discovered by Columbus in 1502, and was opened for traffic with Panamá, on the Pacific coast, by way of the Chagres river, in the 16th century. With the decline of Porto Bello in the 18th century Chagres became the chief Atlantic port of the Isthmus, and was at the height of its importance during the rush of gold-hunters across the Isthmus to California in 1849 and the years following. With the completion of the Panamá railway in 1855, however, travel was diverted to Colón, and Chagres soon became a village of miserable huts, with no evidence of its former importance. On a high rock at the mouth of the river stands the castle of Lorenzo, which was destroyed by Sir Henry Morgan when he captured the town in 1671, but was rebuilt soon afterwards by the Spaniards. Chagres was again captured in 1740 by British forces under Admiral Edward Vernon.

CHAIN-GANG, an American method of handling convicts, working principally on State road construction, stone quarrying and bridge building in the States of Virginia, North Carolina, Georgia, Florida and Alabama. The convicts are generally housed in temporary buildings of rough construction with inadequate sanitary arrangements, and are more or less isolated. In Virginia and Alabama the buildings are of a portable type, similar in construction to an army barrack. In some instances in Georgia a steel wagon cage is used. These cages are about 18 ft. long and 10 ft. wide and sometimes house as many as 18 men, sleeping in triple-decked bunks. The housing conditions differ in the several States, Alabama having by far the best conditions. In all of the camps except Alabama some method of chaining the men who are not trusties is in use. The most common method is the use of the "bull-chain," 4 ft. long, weighing about 3 lb., which is attached to a heavy iron cuff riveted around the right ankle. In going to and from work and during the time the convicts are confined in their quarters, the end of the bull-chain is attached to a long master chain which keeps all of the convicts leashed together. Sometimes, especially in the case of men who have attempted to or who have escaped and been returned, step-chains are used in addition to the bull-chain. These are attached by the use of leg irons, to both ankles, and are from 15 in. to 22 in. in length. Harsh methods of punishment prevail, ranging from solitary confinement on diminished rations to whipping, and, in Georgia, to the use of antiquated stocks and sweat-boxes. While, due to the long outdoor season, the labour of chain-gangs affords a great saving in the cost of road construction and is valuable in the prevention of idleness on the part of prisoners, the chaining of the men cannot help but have a definite demoralizing effect. In addition to the State chain-gangs there are in many localities similar county chain-gangs. (W. B. Co.)

CHAIN MANUFACTURE is the fabrication of a series of links, usually of metal, which are joined together by one of several methods. A chain provides a flexible loop or a connection between objects. The metal of the link is sometimes twisted to form a knot, or welded to strengthen the connection. Many methods of manufacturing chain by hand and machinery are now in vogue. Although a small quantity of chain is used for holding prisoners in check, the bulk of it serves man in various phases of his daily life. On the sea it is used for huge ship anchor chains, deck lashing chains, steering gear chains, buoy chains, etc. Railways use safety chains, brake chains, conductor's valve chains, etc. For motor travel on wet and icy roadways, anti-skid chains are used. Likewise on the farm, in the mine, the forest, the shop or on any extensive engineering operation, usage is found for chain.

There are three general classifications of chain: welded, weldless and transmission, the latter being literally a weldless style. Various materials are used in the manufacture of chain. Precious metals and semi-precious stones are formed into chains for jewellery and ornaments. Industrial chains are made from iron, steel, brass, bronze, nickel, aluminium and other metals or alloys. The large majority of commercial chain is made from wrought iron or steel. Wrought iron has had preference among fire-welded chain makers for many years. Wrought iron is generally regarded as the most reliable material in the manufacture of chains for uses where a failure would endanger life or property. It has considerable ductility, weldability and rust resistance. However, many reliable chains are made from steel.

Workmanship.—Hand and machine-made chain links usually go through several processes before they are ready for assembling into chains. Exceptions are in the instances of links used in cast chain, knotted chains and chain made directly from the solid bar. These processes vary widely in the different types of chain. In hand-made chain, the first operation consists of cutting the bar into short sections to a predetermined length, governed by the size of the link to be made. This short section is flattened, usually called "scarfed," at each end and then bent into a U shape. The scarfed ends are then brought to a welding temperature, threaded through the last finished link, and the weld completed by hammering. To give the welded end a finished appearance, concave tools, called "dollies," are sometimes placed over the weld and by additional hammering on the dollies, the weld is smoothed and shaped. The heating material for the chain maker's furnace is either coke, oil or gas.

By the use of machines some of these operations in this method are eliminated and others made easier. Bars or rods of metal are wound by machine into oval coils and single convolutions of the

coils are cut on an angle of about 45°, thus furnishing single-scarfed links ready for placing in the furnace to be heated. When the scarfed ends are at a welding temperature, the link is removed from the fire, threaded into the last completed link and the weld completed. Completion of the weld is accomplished with the aid of a hand hammer which is used to close the scarfed ends of the link together with a few blows. From this point the weld is completed in a power hammer, equipped with dies which fit over the welded end of the link. These hammers are operated by foot power, direct drive or indirect drive from some remote source of power. Chains made by this method have a slight twist in them. This twist is caused by the coiling operation. When the chain is for uses where this twist would be objectionable the twist is removed in a power hammer having especially designed dies, which straighten each link immediately after it is welded.

Electric Welded Chain.—This is the latest development in welded chain manufacture. A large part of the world's tonnage of small welded chain is now made by this method. Sizes up to ½ in. diameter are commercially made in large quantities. Any of the larger sizes can be electrically welded but manufacturing costs in 1928 were too high. Three types of electric welds are in general use at the present time—the butt weld, the half-butt weld and the flash weld. All of these are of the resistance type, in which the electric current, passing through the material and across the butted ends of the link, produces sufficient heat to raise the metal to the welding or fusing temperature. A later development in electric chain welding is called "percussion welding," but it is not being used commercially. In this latter method, an electrically charged condenser is discharged across the butted ends of a chain link.

Links for electric welding are prepared differently than for fire welding. In the electric method, coils of wire or rods are passed through a chain-forming machine, which automatically straightens the wire, cuts the required length, threads the wire into the last completed link and forms the link, making a continuous chain ready for the welding machine. This butted chain is passed through a chain-welding machine which welds the links. Some welding machines weld alternate links and others consecutive links. They are automatic with one operator attending many machines, or semi-automatic, requiring the services of an operator for each machine. In the electric-weld process the weld is usually made at the side of the link. In the fire-weld process the weld is usually at the end of the link, the exception being certain very large sizes which are sometimes made with the weld at the side. Some electric-welded chain is made with weld at the end of the link, but this is the exception, rather than the rule. In the upset-welding method the links are welded at a relatively low temperature and the butted ends pressed together by a relatively low pressure. This type of weld is characterized by the extruded metal at the weld, forming a bulge which is seldom trimmed off. The semi-upset welding method is similar to the full-upset, with the exception that when the weld is about to be completed a die is placed over one-half the diameter of the material at the butted portion. This die prevents the metal from being forced to the outer side of the link.

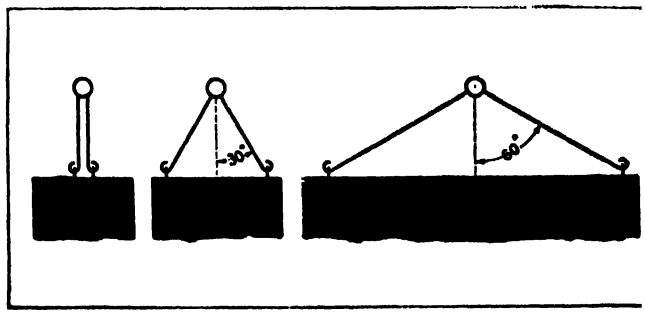
Flash welding is also of the resistance type. It is distinguished by a small amount of metal extruded at the butted ends when the pressure is applied to form the weld. Because of the pressure and closeness of the electrodes, this excess metal, sometimes called the "flash," takes the shape of a flattened ring, differing in this respect from the bulge of the upset-weld. The "flash" is trimmed off close to the diameter of the material, leaving a smooth weld which, when polished, defies detection.

Welded chain is used largely in the straight link variety; however, some use is also made of twisted links. This type has the links twisted so that each link will be in approximately the same plane and therefore lie flat. In the fire-weld method each link is twisted as completed, but in the electric process the completed chain is passed through a machine which automatically twists the links. Other chains which have the same general shape as the welded chains, yet are not welded, include cast chains, which are made by casting metal in properly shaped molds, and solid link chains, made by stamping a solid cuneiform bar into the shape of stiff chain and twisting the individual links apart to make it flexible. The result is a solid, link chain having the appearance of a welded chain.

Anchor Chain.—For ship anchors is used a chain with links having a bar, called a stud, across the inside width of each link. This is called "stud-link" chain and in marine circles is referred to as a chain cable. Both the forming and welding operations are similar to the open link fire-welded chain. After the open link is completed, the stud, concave at each end, is inserted in the link and the sides pressed together. A relatively small amount of stud-link chain is made by a steam hammer process in which the link bars are upset; *i.e.*, balled on the end and scarfed by machines. The scarfed ends are heated and the weld completed on a steam hammer. In cast steel chain the stud is cast at the same time as the balance of the link and becomes a solid part of the link. Studs used in wrought iron chain are either castings or drop forgings. There are several reasons for putting the stud in this type of chain. It prevents the chain from fouling, adds weight to the link and prevents the link from deforming at a relatively low load. It does not increase the tensile strength of the chain, as is generally supposed.

Weldless Chain.—The term "weldless chain" covers a wide range of styles and broadly includes knotted chains, stamped link chains, transmission chains, bead chains, malleable chains, etc. Knotted chains bear a close relationship to the welded chain because they were developed, as a low-priced product, to replace small sizes of welded chain. They are practically all made upon automatic machines which fabricate the chain by straightening the wire, cutting, threading and tying, a single machine making the complete chain from the coil of wire to the finished product. There are about a dozen different styles of these chains in general use. Other forms of weldless wire chains contain no knot and consist simply of twisted wires hooked together—such as jack chain and ladder chain. Stamped link chain such as sash chain and transmission chain require at least two operations in their manufacture. The first operation blanks the links and the second, either automatic or by hand, assembles them. Bead or ball chain, commonly used in electric light fixtures, consists of a series of hollow balls joined by solid bars, the latter having a ball or cross-pipe formed at its ends. This chain is also made entirely by automatic machines. Jewellery chain in an almost endless variety is made from precious metals and used chiefly for ornament. Such chains are often made with oddly shaped links and with combinations of differently shaped links. Those made automatically bear somewhat of a uniform construction throughout their length, while other designs formed and ornamented by hand, vary in details with almost every link.

Finishes used on chain include practically every known finish for which there is a demand. Many chains are sold in their natural finish, as they come from the forge or machine. Some are polished highly by tumbling in sawdust, sand or leather scraps. Protective coatings, such as asphaltum, zinc, tin and lacquer are frequently used. Various colours of paints, powders and japans are used on chains for ornamental purposes, such as chandelier chain. Still others are plated with copper, brass, chromium, cadmium, nickel and other metals or alloys. At present, Cradley Heath, in the Black Country of England, is the centre of heavy-chain manufacture, while York, Pennsylvania, U.S.A., is the centre of small-chain manufacture. (H. M. B.)



Testing.—After welded chain is made it should be given a "proof test" and each link examined for exterior defects. The purpose of this test is to determine if there are any hidden defects which would render the chain unsafe for its rated working load. Any load which is higher than the rated working load yet lower than the elastic limit of the chain link is suitable for this proof test. Railroads, testing bureaus, large users of chain, etc., have specifications giving definite loads to which the various sizes and grades of chain must be tested by the manufacturer. For many years it has been customary to proof test welded chain to a load equal to one-half of the average ultimate tensile strength. Many chain manufacturers continue to follow this practice. Some chain authorities feel that such a load is injurious to the chain links

especially when applied to iron chains. They recommend as a substitute a load about 25% higher than the working load. The statutory proof load required by the British board of trade applying to close-link chain for use on British ships is: proof load to be $12d^2$ tons, where d is the diameter in inches of the iron in the link. For stud-link chain the proof load is 50% higher than for the open-link chain although the tensile strength is practically the same. Knotted types of chain are not proof tested. There are no standard dimensions for chain links. Link dimensions vary with different manufacturers. Well proportioned links can be designed by making the outside dimensions 4½ by 3¼ times the diameter of the material, for close-link chain and 6 by 3.6 times for stud-link chains. These dimensions can be varied.

Destruction Tests.—To determine what ultimate tensile strength may be expected from a finished chain a section several feet long should be tested to destruction. Toughness and ductility of the iron from which the links are made should be given greater consideration than merely high tensile strength when selecting a chain for use where a reliable chain is required. Chain with a high tensile strength is often brittle and will break without warning whereas a chain made from a ductile material will stretch considerably before breaking. Toughness and ductility can best be determined by observing the structure of the break and by the relative amount of reduction in area and the elongation at the point of fracture. These features should be determined in a straight bar of the material from which the links are to be made. Total stretch of a chain before breaking is of little value in determining the toughness and ductility of the material because the elongation of the chain is governed primarily by the shape of the links and not by the composition of the material.

Permissible Loading.—Maximum working loads for chains should be based upon the proof test and should never be higher than the rated working loads suggested by the manufacturer of the chain, individual specifications or testing bureau for the size and grade of chain being considered. Working loads are always given to be used when the chain is lifting in a vertical position. It should be noted (*see* table) that the working load of a chain

Working Loads of Sling Chains When Used at Angles
Wrought Iron Open Link Chain

Size chain, inches	Maximum working load for each branch of sling when used for vertical lift. In lbs.	Maximum working load for each branch of sling when used at angle of 30° from vertical. In lbs.	Maximum working load for each branch of sling when used at angle of 60° from vertical. In lbs.
¼ . .	1,100	950	550
⅜ . .	2,700	2,350	1,350
½ . .	4,500	3,900	2,250
⅝ . .	6,900	6,000	3,450
¾ . .	10,100	8,750	5,050
⅞ . .	14,000	12,000	7,000
1 . .	18,600	16,000	9,300
1¼ . .	28,800	25,000	14,400
1½ . .	40,800	35,000	20,400
1¾ . .	52,500	45,500	26,250
2 . .	66,600	57,500	33,300

when lifting at any angle to the vertical line is always lower than for the vertical lift. When lifting at an angle of 60° to the direction of pull, as with a double sling chain, the working load is only one-half of the working load for the same chain when used for vertical lifting. (H. M. B.; W. L. Gn.)

CHAIN-SHOT, two large bullets or half-bullets fastened together by a chain; formerly used in naval engagements to cut rigging, etc., and sometimes in land battles as a short-range projectile.

CHAIN STORE. The chain store system of merchandising (known in Great Britain as "multiple shops") is largely an American phenomenon. Although chain stores operate extensively in most countries and despite the fact that the chain idea of distribution was practised on a limited scale in China as early as 200 B.C. and in Japan from as early as 1643, chain stores had their real development and growth, as methods of store operation, in the U.S. during the 20th century. Chain store methods spread into the operations of virtually all types of retail establishments until, by the 1950s, they were responsible for approximately 30% of the total retail volume in the United States.

Definition of a Chain.—Marketing associations, the Federal Trade commission and the census of American business differed substantially in their definitions of chains, chiefly on the basis of the nature of merchandise handled and the number of stores operated. In the more common sense, however, retail chain stores are considered to be any system of two or more centrally owned retail stores dealing in substantially similar lines of goods. This definition recognizes three characteristics which must exist before a retail business can be classified as a chain—two or more units, central ownership and basically similar lines of merchandise. Although many chain stores are both centrally owned and operated, central or uniform operation is not a requisite characteristic of a chain store system. In many important chains the store units, though centrally owned and carrying substantially the same lines of goods, are largely individually operated and adapted to the needs and characteristics of the particular markets they serve.

An interesting aspect of this definition is that the various units must carry substantially the same lines of merchandise. This does not mean that they must carry identical lines but rather that the nature of their merchandise must be basically similar. Thus, if two or more stores, centrally owned, handled entirely different types of goods, despite their common ownership these stores could not centralize or pool their buying, exchange strategic merchandising information and in other ways enjoy the advantages of genuine chain store operation. For these reasons, this type of central retail ownership is not considered to be a chain-operated system.

Development in the United States.—The first chain store system in America probably developed with the Hudson's Bay company and its series of trading posts established in Canada prior to 1750. In the United States, the chain store idea was first put into effect by the Great Atlantic and Pacific Tea company in 1858. This company added its second store the following year. Park and Tilford became a chain in 1860, and the F. W. Woolworth company began this type of operation in the variety field in 1879. By 1900, it is estimated, there were about 700 such operations in the United States.

As late as 1920, however, U.S. chain stores were responsible for only about 4% of the total retail trade of the nation. From 1920 to 1930 the system had a spectacular growth. By 1926 it was responsible for approximately 9% of estimated retail sales: by 1930 this percentage had risen to more than 20%. From 1930 to 1933, despite adverse economic conditions, chain stores continued their growth. In 1931 chains were responsible for 21.7% of the total retail trade. In 1933 they produced approximately 25% of the nation's total retail volume. From 1933 to 1939, however, the growth was substantially arrested. The biggest factor obstructing their growth during this period was the extensive enactment of anti-chain store legislation. The rapid rise of the chains had aroused serious concern on the part of local independent retailers. Furthermore, because the chains buy largely directly from manufacturers or producers, circumventing the wholesaler, much of the wholesale trade joined independent retail businesses in their efforts to stop growth of the chains. These two groups exerted a powerful influence on local and national legislative bodies, with the result that restrictive laws were introduced and passed. Some observers then concluded that chain stores had reached their maximum activity and were in the process of de-

cline. Although the growth had been considerably slackened, it was recognized that this method of retail operation had made an outstanding contribution to distribution. In 1944 chains, while operating fewer units, produced 27% of total retail sales. In 1948 the percentage was 29.6% and was produced in 162,655 units whose sales volume totalled $38,691,321,000.

Operating Characteristics.—The explanation of the growing and continued success of the chains lies in their peculiar and economically sound methods of operation. Some of the important characteristics of operation which give them distinct advantages in the field of distribution are as follows:

Large-Scale Buying.—By pooling the merchandise needs of a number of stores, the chains are characteristically in a position to engage in large-scale buying. This buying ability gives them many advantages in the selection of sources, in the establishment of merchandise standards and specifications, in obtaining volume prices and in the maintenance of secure sources of supply.

Direct Buying.—Because of the size of the orders they place, they are usually able to buy directly from producers and manufacturers and thereby cut costs and reduce merchandise delivering time.

Standardized Lines.—Most chain stores concentrate on the handling of standardized lines of staple merchandise. Although some merchandise fashion goods and other specialty items successfully, the broad chain store development has been in staple goods which have had more or less wide universal demand in the territory served by the company. This merchandising policy has helped to reduce markdowns, to increase turnover and to operate at lower costs.

Standardized Operating Methods.—As chains add additional units, they are in an advantageous position to experiment with operating procedures and methods. Out of these experiments they develop efficient merchandising and operating techniques which may become standardized throughout the system.

Selected Locations.—Chain store owners have been particularly conscious of the importance of proper location in the success of their businesses. Partly because of their ability to analyze the value of a particular site and partly because of financial ability to buy the locations they want, chain stores often occupy the best retail sites. Some chains, however, because of the nature of the merchandise they handle and the consumer acceptance they enjoy, do not need central locations. These stores have been extremely successful in moving away from central shopping districts and establishing separate shopping areas of their own.

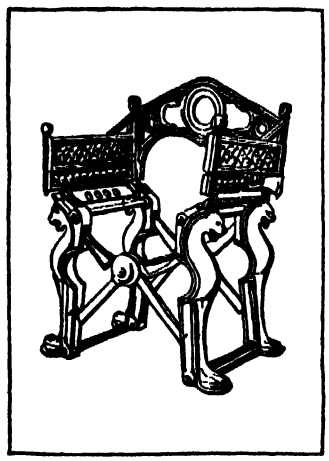
Distributed Risks.—Through the operation of many units, chain stores are able to distribute and balance co-operatively merchandising and operating risks.

Although almost every type of retail store may be chain operated, the system has been most successful in the merchandising of such lines as variety merchandise, shoes, automobile accessories, dairy products, groceries and meats, cigars and tobacco, drugs, paint and glass, newspapers and magazines and women's ready-to-wear clothing. In all these lines more than 25% of retail sales are made through chains.

(O. P. R.)

Great Britain.—There are two main types of chain store in Great Britain, the multiple shop and the "variety" chain store, both of which developed in the second half of the 19th century. By 1900 there were important multiple tea dealers, grocers and provision merchants, chemists, news agents and tobacconists. Examples of the variety chain stores were the Penny Bazaars which flourished at the end of the 19th century; Marks and Spencer, first opened in 1887; and Woolworth, which spread from the United States to England in 1910.

In 1950, according to the first census of distribution, retail firms (other than co-operative societies) with ten or more establishments (branches) handled retail sales to the value of £1,156,000,000; that is, [illegible] of a total of £4,923,000,000 handled by all retail shops. More than 80% of the trade of the multiples was handled by firms with 25 or more branches. The share of multiples with ten or more branches in the principal divisions of retail trade was: 34% in chemists' goods, 31% in clothing, 25% in hardware, 25% in books and stationery, 23% in furniture, 22% in groceries, 18% in other food retailing, 12% in confectionery, tobacco and newspapers and 9% in jewellery, sports goods and fancy goods. Variety stores were almost exclusively of the multiple type.



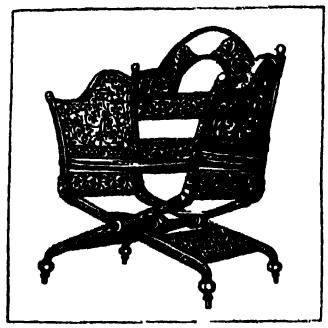
Most multiple organizations developed from small retailing beginnings. In a few trades (*e.g.*, in footwear) some manufacturers set up their own chains of retail shops. In others some multiples extended their operations by going into manufacturing. The "tied house" system of the brewing industry is a form of retailing which has some but not all of the typical characteristics of multiple store control and management.

The growth of multiple trading in the 20th century became an important competitive force in retailing, affecting the small-scale independent shopkeepers, the department stores and the co-operative societies. In Great Britain, unlike some other European countries and the United States, no government measures have ever been introduced to control the growth or to handicap the operation of multiple firms. There has been no discriminatory taxation. In 1937 an unsuccessful attempt was made to introduce a private bill in parliament to restrict the activities and growth of multiples. (B. S. Y.)

CHAIR, a movable seat, usually with four legs and for a single person, the most varied and familiar article of domestic furniture. (In Mid. Eng. *chaere,* through O.Fr. *chaëre* or *chaiere,* from Lat. *cathedra,* later *caledra,* Gr. *καθέρα* seat, *cf.* "cathedral"; the modern Fr. form *chaise,* a chair, has been adopted in English with a particular meaning as a form of carriage; *chaire* in French is still used of a professorial or ecclesiastical "chair," or *cathedra.*) The chair is of extreme antiquity, although for many centuries and indeed for thousands of years it was an appanage of state and dignity rather than an article of ordinary use. "The chair" is still extensively used as an emblem of authority. It was not until the 16th century that it became common anywhere. The chest, the bench and the stool were until then the ordinary seats of everyday life, and the number of chairs which have survived from an earlier date is exceedingly limited; most of such examples are of ecclesiastical or seigneurial origin.

Ancient Chairs.—In ancient Egypt they were of great richness and splendour. Fashioned of ebony and ivory, or of carved and gilded wood, they were covered with costly stuffs and supported upon representations of the legs of beasts of the chase or the figures of captives. The earliest monuments of Nineveh represent a chair without a back but with carved legs ending in lions' claws or bulls' hoofs; others are supported by figures in the nature of caryatides or by animals. The earliest known form of Greek chair, going back to five or six centuries before Christ, had a back but stood straight up, front and back. On the frieze of the Parthenon Zeus occupies a square seat with a bar-back and thick turned legs; it is ornamented with winged sphinxes and the feet of beasts. The characteristic Roman chairs were of marble, also adorned with sphinxes; the curule chair was originally very similar in form to the modern folding chair, but eventually received a good deal of ornament.

The most famous of the very few chairs which have come down from a remote antiquity is the reputed chair of St. Peter in St. Peter's at Rome. The wooden portions are much decayed, but it would appear to be Byzantine work of the 6th century, and to be really an ancient *sedia gestatoria.* It has ivory carvings representing the labours of Hercules. A few pieces of an earlier oaken chair have been let in; the existing one, Gregorovius says, is of acacia wood. The legend that this was the curule chair of the senator Pudens is necessarily apocryphal. It is not, as is popularly supposed, enclosed in Bernini's bronze chair, but is kept under triple lock and exhibited only once in a century.



"DAGOBERT CHAIR," OF CAST BRONZE AND PROBABLY MORE THAN 1,000 YEARS OLD

Byzantium, like Greece and Rome, affected the curule form of chair, and in addition to lions' heads and winged figures of Victory and dolphin-shaped arms used also the lyre-back which has been made familiar by the pseudo-classical revival of the end of the 18th century. The chair of Maximian in the cathedral of Ravenna is believed to date from the middle of the 6th century. It is of marble, round, with a high back, and is carved in high relief with figures of saints and scenes from the Gospels—the Annunciation, the Adoration of the Magi, the flight into Egypt, and the baptism of Christ. The smaller spaces are filled with carvings of animals,

birds, flowers and foliated ornament. Another very ancient seat is the so-called "Chair of Dagobert" in the Louvre. It is of cast bronze, sharpened with the chisel and partially gilt; it is of the curule or faldstool type and supported upon legs terminating in the heads and feet of animals. The seat, which was probably of leather, has disappeared. Its attribution depends entirely upon the statement of Suger, abbot of St. Denis in the 12th century, who added a back and arms. Its age has been much discussed, but Viollet-le-Duc dated it to early Merovingian times.

To the same generic type belongs the famous abbots' chair of Glastonbury; such chairs might readily be taken to pieces when their owners travelled. The *faldisternium* in time acquired arms and a back, while retaining its folding shape. The most famous, as well as the most ancient, English chair is that made at the end of the 13th century for Edward I., in which most subsequent monarchs have been crowned. It is of an architectural type and of oak, and was covered with gilded *gesso* which long since disappeared.

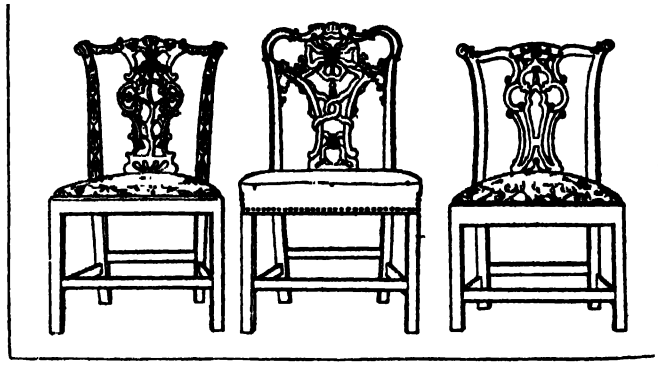
SPANISH ARMCHAIR OF THE 17TH CENTURY, HEAVY IN CONSTRUCTION AND ELABORATELY CARVED

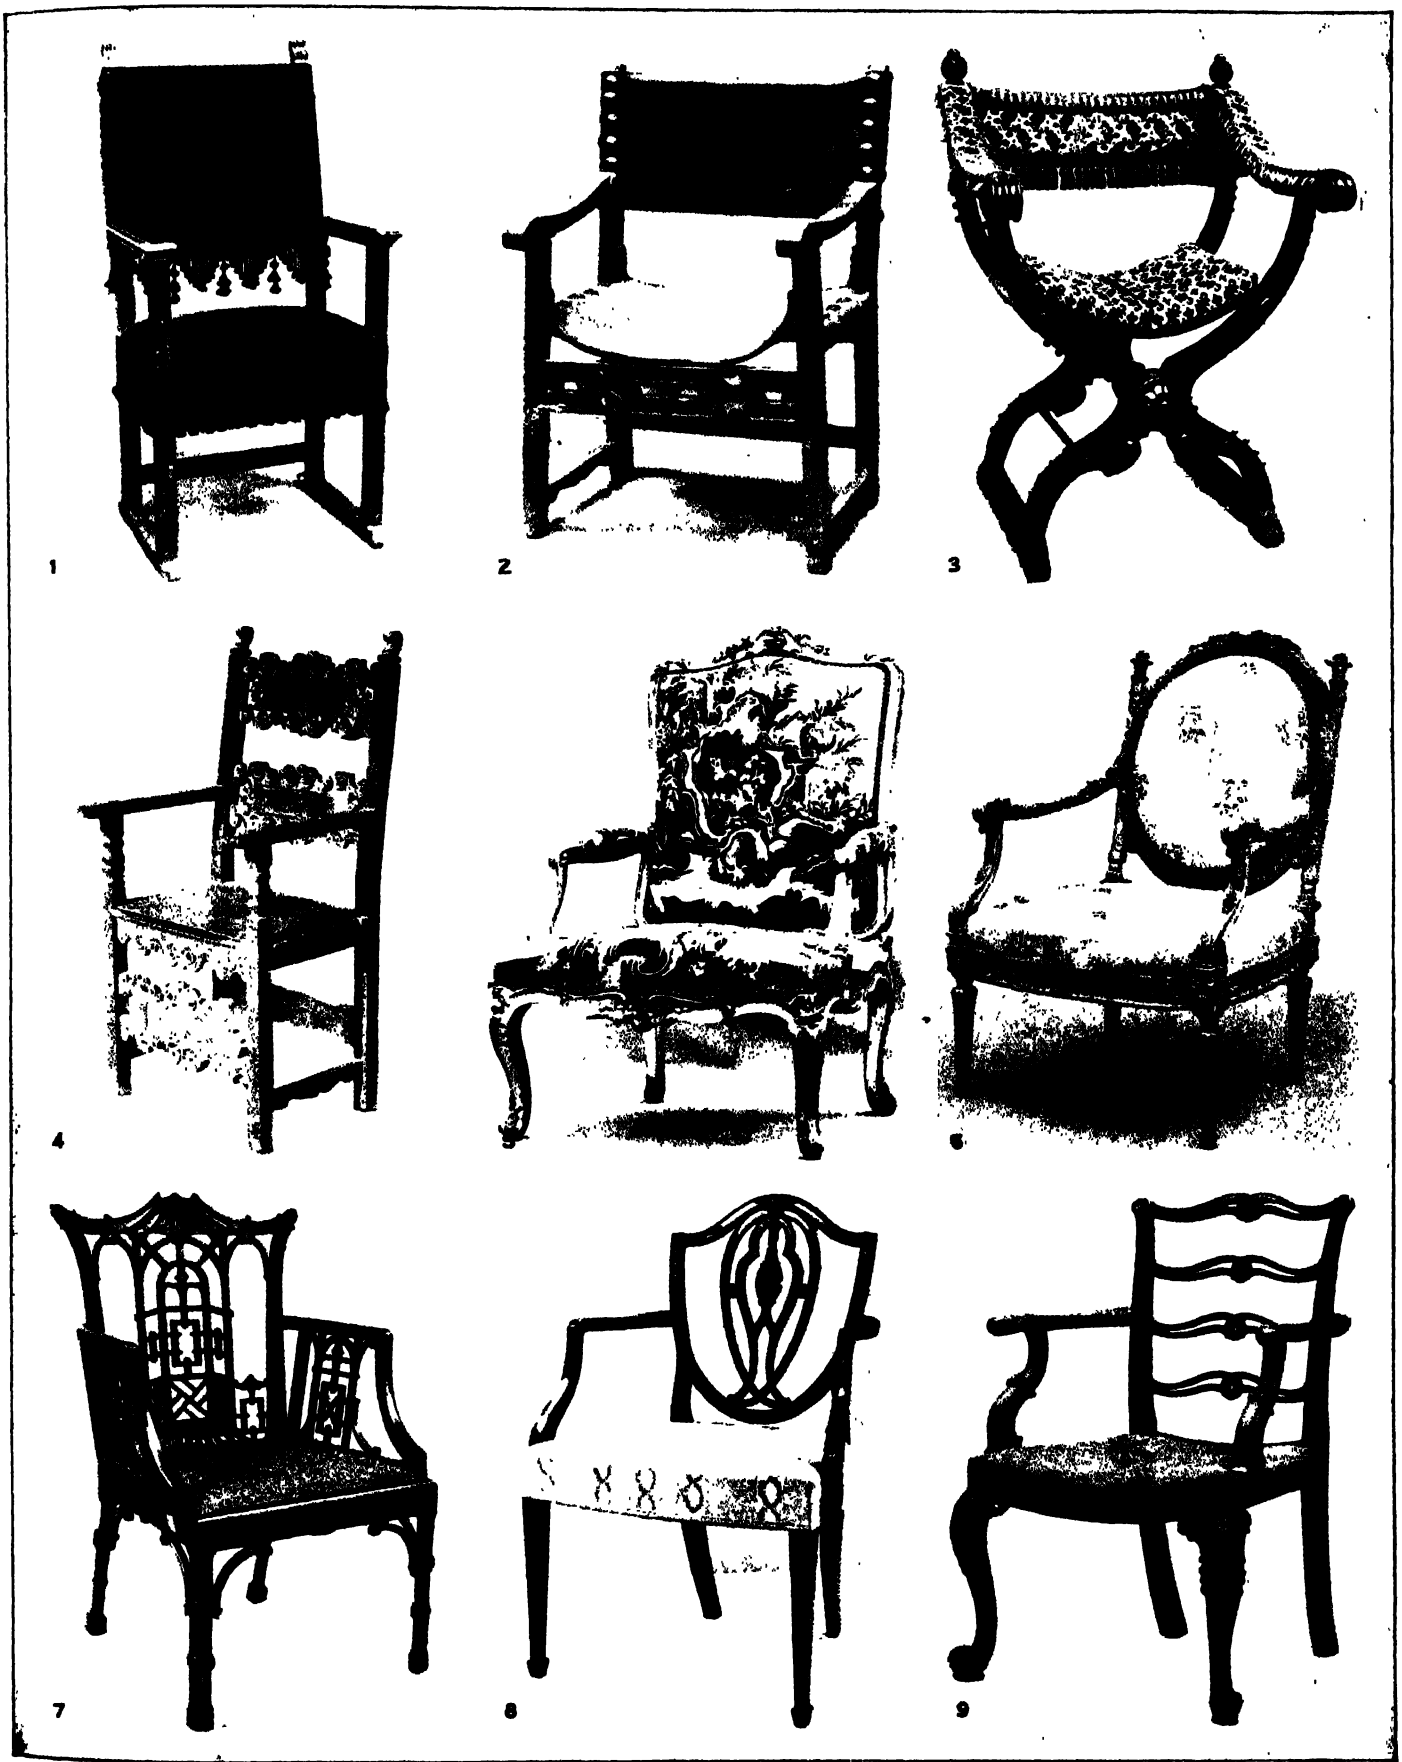


Transition.—Passing from these historic examples we find the chair monopolized by the ruler, lay or ecclesiastical, to a comparatively late date. As the seat of authority it stood at the head of the lord's table, on his dais, by the side of his bed. The seigneurial chair, commoner in France and the Netherlands than in England, is a very interesting type, approximating in many respects to the episcopal or abbatial throne or stall. It early acquired a very high back and sometimes had a canopy. Arms were invariable, and the lower part was closed in with panelled or carved front and sides—the seat, indeed, was often hinged and sometimes closed with a key. That we are still said to sit "in" an arm-chair and "on" other kinds of chairs is a reminiscence of the time when the lord or seigneur sat "in his chair." These throne-like seats were always architectural in character, and as Gothic feeling waned took the distinctive characteristics of Renaissance work. It was owing in great measure to the Renaissance that the chair ceased to be an appanage of state, and became the customary companion of whomsoever could afford to buy it. Once the idea of privilege faded the chair speedily came into general use, and almost at once began to reflect the fashions of the hour. No other piece of furniture has ever been so close an index to sumptuary changes. It has varied in size, shape and sturdiness with the fashion of women's dress as well as men's. Thus the chair which was not, even with its arms purposely suppressed, too ample during the several reigns of some form or other of hoops and farthingale, became monstrous when these protuberances disappeared. Again, the costly laced coats of the dandy of the 18th and early 19th centuries were so threatened by the ordinary form of seat that a "conversation chair" was devised, which enabled the buck and the ruffler to sit with his face to the back, his valuable tails hanging unimpeded over the front. The early chair almost invariably had arms, and it was not until towards the close of the 16th century that the smaller form grew common.

The 17th Century.—The majority of the chairs of all countries until the middle of the 17th century were of oak without upholstery, and when it became customary to cushion them, leather was sometimes employed; subsequently velvet and silk were extensively used, and at a later period cheaper and often more durable materials. Leather was not infrequently used even for the costly and elaborate chairs of the faldstool form—occasionally sheathed in thin plates of silver—which Venice sent all over Europe. To this day, indeed, leather is one of the most frequently employed materials for chair covering. The outstanding characteristic of most chairs until the middle of the 17th century was massiveness and solidity. Being usually made of oak, they were of considerable weight, and it was not until the introduction of the handsome Louis XIII. chairs with cane backs and seats that either weight or solidity was reduced. Although English furniture derives so extensively from foreign and especially French and Italian models, the earlier forms of English chairs owed but little to exotic influences.

This was especially the case down to the end of the Tudor period, after which France began to set her mark upon the British chair. The squat variety, with heavy and sombre back, carved like a piece of panelling, gave place to a taller, more slender, and more elegant form, in which the framework only was carved, and attempts were made at ornament in new directions. The stretcher especially offered opportunities which were not lost upon the cabinet-makers of the Restoration. From a mere uncompromising cross-bar intended to strengthen the construction, it blossomed into an elaborate scroll-work or an exceedingly graceful semi-circular ornament connecting all four legs, with a vase-shaped knob in the centre. The arms and legs of chairs of this period were scrolled, the splats of the back often showing a rich arrangement of spirals and scrolls. This most decorative of all types appears to have been popularized in England by the cavaliers who had been in exile with Charles II. and had become familiar with it in the north-western parts of the European Continent.

During the reign of William and Mary these charming forms degenerated into something much stiffer and more rectangular, with a solid, more or less fiddle-shaped splat and a cabriole leg with pad feet. The more ornamental examples had cane seats and ill-proportioned cane backs. From these forms was gradually developed the Chippendale chair, with its elaborately interlaced back, its graceful arms and square or cabriole legs, the latter terminating in the claw and ball or the pad foot. Hepplewhite Sheraton and Adam all aimed at lightening the chair, which, even in the master hands of Chippendale, remained comparatively heavy. The endeavour succeeded, and the modern chair is everywhere comparatively slight. Chippendale and Hepplewhite between them determined what appears to be the final form of the chair, for since their time practically no new type has lasted, and in its main characteristics the chair of the 20th century is the direct derivative of that of the later 18th.



The 18th century was, indeed, the golden age of the chair, especially in France and England, between which there was considerable give and take of ideas. Diderot could not refrain from writing of them in his *Encyclopédie*. The typical Louis Seize chair, oval-backed and ample of seat, with descending arms and round-reeded legs, covered in Beauvais or some such gay tapestry woven with Boucher or Watteau-like scenes, is a very gracious

CHIPPENDALE CHAIRS, WHICH IN THE 18TH CENTURY REPLACED THE HEAVIER MODELS OF TRADITION

object, in which the period reached its high-water mark. Th Empire brought in squat and squabby shapes, comfortable enoug no doubt, but entirely destitute of inspiration. English Empi chairs were often heavier and more sombre than those of Frenc design. Thenceforward the chair in all countries ceased to a tract the artist. The *art nouveau* school has occasionally produce something of not unpleasing simplicity; but more often its effort have been frankly ugly or even grotesque. There have been prac tically no novelties. So much, indeed, is the present indebted t the past in this matter that even the revolving chair, now s

familiar in offices, has a pedigree of something like four centuries (*see* also INTERIOR DECORATION). (J. P.-B.)

CHAISE, a light two- or four-wheeled carriage with a movable hood or "calash" (the French for "chair," through a transference from a "sedan-chair" to a wheeled vehicle). The "post-chaise" was the fast-travelling carriage of the 18th and early 19th centuries. It was closed and four-wheeled for two or four horses and with the driver riding postillion.

CHAITANYA, Indian mystic, was born in 1485 at Navidvip, Bengal (died *c.* 1534). He was educated at the pathsala, or primary school of Navidvip and at eight years of age entered the Sanskrit tol. At an early age he became proficient in Sanskrit grammar and rhetoric. He initiated a popular religious movement within the Vaishnava faith (a cult of Vishnu). Chaitanya emphasized the path of bhakti (of devotion and direct relation to God) in contrast to the priestcraft and religious convention of the day. The Chaitanya Vaishnavas are a distinct religious sect in India to-day and the sankirton (chorus singing accompanied by drums and cymbals), emphasized and developed by Chaitanya, still forms the centre of its religious rites.

CHAKMA, a tribe in India, of mixed origin, probably the descendants of prisoners taken by the Arakanese from the Mogul armies who were provided with Magh, Mon or Arakanese wives. It migrated from the southern portion of the Chittagong coastal plain towards the end of the 18th century and is now settled on the middle reaches of the Karnaphuli and its tributaries in the Chittagong Hills tracts. The language is a dialect of Bengali, but the old script, now falling into disuse, is closely allied to the ancient Khmer script. The men dress in Bengali style, but the women wear a distinctive long blue skirt with a red border, and after puberty a strip of silk over the breasts. The religion is Animism, with a thin veneer of Buddhism. The dead are burned on the banks of streams. The tribe is divided into patrilineal endogamous clans, but the power of the heads of the separate clans has in course of time been absorbed by one family, the head of whom is known as the Chakma chief. Despite strong and prolonged Bengali influence the underlying culture is Burmese or Mon. Only of recent years is shifting cultivation being gradually abandoned for plough cultivation. The houses are flimsily built on piles and the villages are invariably on the banks of streams.

See T. H. Lewin, *Hill Tracts of Chittagong and Dwellers Therein* (Calcutta, 1869); G. A. Grierson, *Linguistic Survey of India*, vol. v., part 9. (J. P. M.)

CHAKRATA, a small mountain cantonment in the Dehra Dun district of the United Provinces of India, on the range of hills overlooking the valleys of the Jumna and the Tons, at an elevation of 7,000 ft.

CHALCEDON, more correctly **CALCHEDON,** an ancient maritime town of Bithynia, in Asia Minor, almost directly opposite Byzantium, south of Scutari. It was a Megarian colony founded on a site so obviously inferior to that which was within view on the opposite shore, that it received from the oracle the name of "the City of the Blind." In its early history it shared the fortunes of Byzantium, vacillated long between the Lacedaemonian and the Athenian interests, and was at last bequeathed to the Romans by Attalus III. of Pergamum (133 B.C.). It was partly destroyed by Mithridates, but recovered during the Empire, and in A.D. 451 was the seat of the Fourth General Council. It fell under the repeated attacks of the barbarian hordes who crossed over after having ravaged Byzantium, and furnished an encampment to the Persians under Chosroes, *c.* 616–626. The Turks used it as a quarry for building materials for Constantinople. To the south are the ruins of Panteichion, where Belisarius is said to have lived in retirement.

See J. von Hammer, *Constantinopolis* (Pesth, 1822); Murray's *Handbook for Constantinople* (London, 1900).

CHALCEDON, COUNCIL OF, the fourth oecumenical council of the Catholic Church, was held in 451, its occasion being the Eutychian heresy and the notorious "Robber Synod" (*see* EUTYCHES and EPHESUS, COUNCILS OF), which called forth vigorous protests both in the East and West, and a loud demand for a new general council, a demand that was ignored by the Eutychian Theodosius II., but speedily granted by his successor, Marcian. In response to the imperial summons, 500 to 600 bishops, all Eastern, except the Roman legates and two Africans, assembled in Chalcedon on Oct. 8, 451. The bishop of Rome claimed for his legates the right to preside, and insisted that any act that failed to receive their approval would be invalid. The first session was tumultuous; party feeling ran high, and scurrilous epithets were bandied to and fro. The acts of the Robber Synod were examined; fraud, violence and coercion were charged against it; its entire proceedings were annulled, and, at the third session, its leader, Dioscurus, was deposed and degraded. The emperor requested a declaration of the true faith; but the sentiment of the council was opposed to a new symbol. It contented itself with reaffirming the Nicene and Constantinopolitan creeds and the Ephesine formula of 431, and accepting, only after examination, the Christological statement contained in the *Epistola Dogmatica* of Leo I. (*q.v.*) to Flavianus. Thus the council rejected both Nestorianism and Eutychianism, and stood upon the doctrine that Christ had two natures, each perfect in itself and each distinct from the other, yet perfectly united in one person, who was at once both God and man. With this statement, which was formally subscribed in the presence of the emperor, the development of the Christological doctrine was completed, but not in a manner to obviate further controversy (*see* MONOPHYSITES and MONOTHELITES).

The remaining sessions were occupied with matters of discipline, episcopal jurisdiction, organization of diocese and parish, occupations of the clergy and the like; and confirmed the third canon of the second oecumenical council, which accorded to Constantinople equal privileges (ἴσα πρεσβεῖα) with Rome, and the second rank among the patriarchates, and, in addition, granted to Constantinople patriarchal jurisdiction over Pontus, Asia and Thrace. The Roman legates, who were absent (designedly?) when this famous (xxviii.) canon was adopted, protested against it, but in vain, the imperial commissioners deciding in favour of its regularity and validity. Leo I., although he recognized the council as oecumenical and confirmed its doctrinal decrees, rejected canon xxviii. on the ground that it contravened the 6th canon of Nicaea and infringed the rights of Alexandria and Antioch. In what proportion zeal for the ancient canons and the rights of others, and jealous fear of encroachment upon his own jurisdiction, were mixed in the motives of Leo, it would be interesting to know. The canon was universally received in the East (*see* CONSTANTINOPLE, COUNCILS OF).

The emperor Marcian approved the doctrinal decrees of the council and enjoined silence in regard to theological questions. Eutyches and Dioscurus and their followers were deposed and banished.

See Hefele, *Church Councils* (2nd ed.) ii. pp. 394–578 (Eng. trans., iii. pp. 268–464); also bibliographies in Herzog-Hauck, *Realencyklopädie*, 3rd ed., *s.v.*, "Eutyches" (by Loofs) and *s.v.* "Nestorianer" (by Kessler); and the general histories of Christian Doctrine.

CHALCEDONY or **CALCEDONY,** a variety of native silica occurring in concretionary, mammillated or stalactitic forms of waxy lustre and a great variety of colours—usually bluish white, grey, yellow or brown. It has a compact fibrous structure and a fine splintery fracture. Its relation to quartz has been the subject of a long controversy; one theory supposed it to be a mixture of quartz and opal, while the other held that it was a mineral distinct from quartz. Chalcedony fibres are usually, though not invariably, uniaxial and positive, but differ from quartz in that the optic axis is perpendicular to the length. Further, the refractive indices, double refraction, specific gravity and hardness are all slightly less for chalcedony than for quartz. The fine structure of the two minerals must, however, be very similar for their X-ray powder-photographs are identical. This result, which favours the view that chalcedony is a mixture of quartz and opal, is further supported by optical considerations; for by assigning reasonable values to the density, refractive index and amount of the opal supposed to be present, it is possible to account for all the characters of chalcedony.

Chalcedony occurs in veins and amygdules of volcanic rocks

together with zeolites and other hydrated silicates. It is deposited from residual magmatic solutions as well as being entirely secondary. In this mode of occurrence it is a common mineral in many volcanic fields, as in the basalts of northern Ireland, the Faroe Islands, Iceland, the Deccan (India). Chalcedonic pseudomorphs after other minerals often give rise to very interesting specimens. The name "enhydros" is given to hollow nodules of chalcedony containing water and an air bubble which is visible through the semitransparent wall. In all ages chalcedony has been the stone most used by the gem engraver, and many coloured varieties, described under special headings, are still cut and polished as ornamental stones. (*See* AGATE; BLOODSTONE OR HELIOTROPE; CARNELIAN OR CORNELIAN; CHRYSOPRASE; MOCHA STONE; ONYX.) (W. A. W.)

CHALCIS or KHALKIS, the chief town of the island of Euboea, Greece, is on the strait of the Euripus at its narrowest point. Pop. (1951) 23,768. Ancient Chalcis was peopled by Ionians, and early developed industrial and colonizing activity. In the 7th and 8th centuries it founded 30 townships on the peninsula of Chalcidice, and several important cities in Sicily (*q.v.*). Its metalwork, purple and pottery found markets among these settlements, and were distributed widely in the ships of its allies Corinth and Samos. In the so-called Lelantine War, Chalcis won from its neighbour and rival Eretria the best agricultural district of Euboea and became the chief city of the island. But its prosperity was broken by disastrous wars with the Athenians, and it became a member of both the Delian Leagues. In the Hellenistic period it was one of the fortresses by which Macedon controlled Greece. Antiochus III of Syria (192) and Mithradates VI of Pontus (88) used it as a base for invading Greece. Under Roman rule Chalcis retained some commercial prosperity; after the 6th century A.D. it again served to protect central Greece against northern invaders. From 1209 it was under Venetian control; in 1470 it passed to the Ottoman Turks, who made it the seat of a pasha. In 1688 it was successfully held against Venetian attack. The modern town has considerable export trade and railway connection with Athens and Peiraeus (1904). The old walled Castro, toward the Euripus, is inhabited by Jewish and Turkish families; the modern suburb outside it, by Greeks. A part of the Castro was destroyed by the earthquake of 1894; part, the famous "Black Bridge," which gave its mediaeval name "Negroponte" to Euboea, has been replaced by a modern swing bridge in the widening of the Euripus. The church of St. Paraskeve, once the chief church of the Venetians, dates from the Byzantine period, though many of its details are Western. The Turkish mosque was turned into a guardhouse.

CHALCOCITE, a mineral consisting of cuprous sulphide (Cu_2S), crystallizing in the orthorhombic system. It is known also as copper glance, redruthite and vitreous copper. The crystals have the form of six-sided tables or prisms which are usually twinned, with the result that they simulate hexagonal symmetry. The mineral more often occurs as compact masses, which are sometimes of considerable extent. The colour is dark lead gray with a metallic lustre, but this is never very bright, since the material is readily altered, becoming black and dull on exposure to light. The mineral is soft (H.=2½) and sectile; specific gravity 5.7. It has a hexagonal polymorph not known to occur in nature.

Next to chalcopyrite, chalcocite is the most important ore of copper, and is perhaps the most characteristic mineral of the zone of secondary enrichment. It seems probable however that at some localities, *e.g.*, Butte, Mont., it is of primary origin. The best crystals are from St. Just, St. Ives and Redruth in Cornwall, and from Bristol in Connecticut. (CL. F.)

CHALCONDYLES (or CHALCOCONDYLAS), **LAONICUS,** the only Athenian Byzantine writer. He wrote a history, in ten books, of the period from 1298–1463, describing the fall of the Greek empire and the rise of the Ottoman Turks, down to the conquest of the Venetians and Mathias, king of Hungary, by Mohammed II. The capture of Constantinople he rightly regarded as an event of far-reaching importance. The work incidentally gives an interesting sketch of the civilization of England, France and Germany, whose assistance the Greeks sought against the Turks. Chalcondyles' chronology is defective, and his use of the old Greek place names causes confusion.

Editio princeps, ed. J. B. Baumbach (1615); In Bonn *Corpus Scriptorum Hist. Byz.* ed. I. Bekker (1843); Migne, *Patrologia Graeca*, clix. There is a French translation by Blaise de Vigenère (1577, later ed. by Artus Thomas with valuable illustrations on Turkish matters); *see* also F. Gregorovius, *Geschichte der Stadt Athen im Mittelalter*, ii (1889); Gibbon, *Decline and Fall*, ch. 66; C. Krumbacher, *Geschichte der byzantinischen Literatur* (1897). There is a biographical sketch of Laonicus and his brother in Greek by Antonius Calosynas, a physician of Toledo, who lived in the latter part of the 16th century (*see* C. Hopf, *Chroniques gréco-romanes*, 1873).

His brother, DEMETRIUS CHALCONDYLES (1424–1511), was born in Athens. In 1477 he went to Italy, where Cardinal Bessarion became his patron. He became famous as a teacher of Greek and the Platonic philosophy; in 1463 he was made professor at Padua, and in 1479 was summoned by Lorenzo de' Medici to Florence. In 1492 he removed to Milan, where he died in 1511. He was associated with Marsilius Ficinus, Angelus Politianus and Theodorus Gaza, in the revival of letters in the western world. One of his pupils at Florence was the famous John Reuchlin. Demetrius Chalcondyles published the editio princeps of Homer (1488), Isocrates (1493) and Suidas (1499), and a Greek grammar (*Erotemata*) in the form of question and answer.

BIBLIOGRAPHY.—H. Hody, *De Graecis illustribus* (1742); C. Hopf, *Chroniques gréco-romanes* (1873); E. Legrand, *Bibliographie hellénique*, i (1885).

CHALCOPYRITE or **COPPER-PYRITES,** a copper iron sulphide ($CuFeS_2$), an important ore of copper.

Chalcopyrite crystallizes in the scalenohedral class of the tetragonal system, but the form is so nearly cubic that it was not recognized as tetragonal until accurate measurements were made in 1822. Crystals are usually tetrahedral in aspect but frequently twinned, and they are often complex and difficult to decipher. The fracture is conchoidal, and the material is brittle. Hardness 4; specific gravity 4.2. The colour is brass-yellow, and the lustre metallic; the streak, or colour of the powder, is greenish-black. The mineral is especially liable to surface alteration, tarnishing with beautiful iridescent colours; a blue colour usually predominates, probably due to the alteration of the chalcopyrite to covellite (CuS). It is commonly found massive, granular to compact.

Chalcopyrite may be readily distinguished from pyrite (or iron pyrites), which it somewhat resembles in appearance, by its deeper colour and lower degree of hardness: the former is easily scratched by a knife, while the latter can only be scratched with difficulty or not at all. Chalcopyrite is decomposed by nitric acid with separation of sulphur and formation of a green solution; ammonia added in excess to this solution changes the green colour to deep blue and precipitates red ferric hydroxide.

The chemical formula $CuFeS_2$ corresponds with the percentage composition Cu=34.5, Fe=30.5, S=35.0. However, analyses usually show the presence of more iron, due to the intimate admixture of pyrite. Traces of gold, silver, selenium or thallium are sometimes present, and the mineral is sometimes worked as an ore of gold or silver, which may be present in solid solution.

Chalcopyrite is of wide distribution and is the commonest of the ores of copper. Extensive deposits are mined in the United States, particularly at Butte, Mont., and in Namaqualand, South Africa. Well-crystallized specimens are met with at many localities; for example, formerly at Wheal Towan in the St. Agnes district of Cornwall, Eng., at Freiberg in Saxony, Ger., and Joplin, Mo. (L. J. S.; CL. F.)

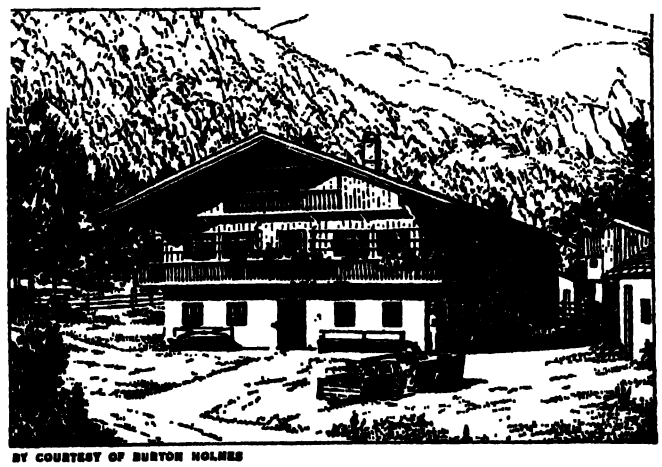
CHALDAEA (CHALDEA). "Chaldaea" and "Chaldaeans" are frequently used in the Old Testament as equivalents for "Babylonia" and "Babylonians." Chaldaea was really the name of a country, used in two senses. It was first applied to the extreme southern district, whose ancient capital was the city of *Bit*

Yakîn, the chief seat of the renowned Chaldaean rebel Merodach-baladan, who harassed the Assyrian kings Sargon and Sennacherib. It is not as yet possible to fix the exact boundaries of the original home of the Chaldaeans, but it may be regarded as having been the long stretch of alluvial land situated at the then separate mouths of the Tigris and Euphrates, which rivers now combine to flow into the Persian Gulf in the waters of the majestic *Shatt el-'Arab*.

The name "Chaldaea," however, soon came to have a more extensive application. In the days of the Assyrian king Adad-nirâri III. (811–782 B.C.), the term *mat Kaldû* covered practically all Babylonia. Furthermore, Merodach-baladan was called by Sargon II (722–705 B.C.) "king of the land of the Chaldaeans" and "king of the land of Bît Yakîn" after the old capital city; but there is no satisfactory evidence that Merodach-baladan had the right to the title "Babylonian." The racial distinction between the Chaldaeans and the Babylonians proper seems to have existed until a much later date. That they differed from the Arabs and Aramaeans appear to follow from the distinction made by Sennacherib (705–681 B.C.) between the Chaldaeans and these races. Later, during the period covering the fall of Assyria and the rise of the Neo-Babylonian empire, the term *mat Kaldû* was not only applied to all Babylonia, but also embraced the territory of certain foreign nations who were later included by Ezekiel (xxiii. 23) under the expression "Chaldaeans."

The Chaldaeans probably first came from Arabia, the supposed original home of the Semitic races, at a very early date along the coast of the Persian Gulf and settled in the neighbourhood of Ur ("Ur of the Chaldees," Gen. xi. 28), whence they began a series of encroachments, partly by warfare and partly by immigration, against the other Semitic Babylonians. These aggressions after many centuries ended in the Chaldaean supremacy of Nabopolassar and his successors (from *c.* 625), although there is no positive proof that Nabopolassar was purely Chaldaean in blood. The sudden rise of the later Babylonian empire under Nebuchadnezzar, the son of Nabopolassar, must have tended to produce so thorough an amalgamation of the Chaldaeans and Babylonians, who had theretofore been considered as two kindred branches of the same original Semite stock, that in the course of time no perceptible differences existed between them. The language of these Chaldaeans differed in no way from the ordinary Semitic Babylonian idiom which was practically identical with that of Assyria. Consequently, the term "Chaldaean" came quite naturally to be used in later days as synonymous with "Babylonian," and through a misunderstanding the term *Chaldee* (*q.v.*) was subsequently applied to the Aramaic language.

The derivation of the name "Chaldaean" is uncertain. It is probably connected with the Semitic stem *kasâdu* (conquer), in which case *Kaldi-Kašdi*, with the well-known interchange of *l* and *š*, would mean "conquerors." It is also possible that *Kašdu-Kaldû* is connected with the proper name Chesed, who is represented as having been the nephew of Abraham (Gen. xxii. 22). But there is no connection between the Black sea people called "Chaldaeans" by Xenophon (*Anab.* vii. 25) and the Chaldaeans of Babylonia. (For *Chaldians see* URARTU.)



In Daniel, the term "Chaldaeans" commonly means "astrologers, astronomers," as it also does in the classical authors (Herodotus, Strabo, Diodorus, etc.). In Daniel i. 4, by the expression "tongue of the Chaldaeans," the writer evidently meant the language in which the celebrated Babylonian works on astrology and divination were composed. It is now known that the literary idiom of the Babylonian wise men was the non-Semitic Sumerian; but it is not probable that the late author of *Daniel* (*q.v.*) was aware of this fact. The word "Chaldaean" is applied as a race-name to the Babylonians (Dan. iii. 8, v. 30, ix. 1); but the expression is used oftener, either as a name for some special class of magicians, or as a term for magicians in general (ix. 1). The transfer of the name of the people to a special class can perhaps be explained. When in later times "Chaldaean" and "Babylonian" became practically synonymous, the term "Chaldaean" lived on in the secondary restricted sense of "wise men." The early *Kaldi* had seized and held from very ancient times the region of old Sumer, which was the centre of the primitive non-Semitic culture. It seems extremely probable that these Chaldaean Semites were so strongly influenced by the foreign civilization as to adopt it eventually as their own. Then, as the Chaldaeans soon became the dominant people, the priestly caste of that region developed into a Chaldaean institution. It is reasonable to conjecture that southern Babylonia, the home of the old culture, supplied Babylon and other important cities with priests, who from their descent were correctly called "Chaldaeans." This name in later times, owing to the racial amalgamation of the Chaldaeans and Babylonians, lost its former national force, and became, as it occurs in Daniel, a distinctive appellation of the Babylonian priestly class. *Kalû* (priest) in Babylonian, which has no etymological connection with *Kaldû*, may have contributed paronomastically towards the popular use of the term "Chaldaeans" for the Babylonian magi. (*See* also ASTROLOGY.)

See BABYLONIA AND ASSYRIA and the commentaries on the book of Daniel. (J. D. PR.)

CHALDEE, a term formerly applied to the Aramaic portions of the biblical books of Ezra and Daniel or to the vernacular paraphrases of the Old Testament (*see* TARGUM), on the assumption that the language was that of Chaldaea (*q.v.*). But the cuneiform inscriptions show that the language of the Chaldaeans was Assyrian; and it is now known that the substitution of Aramaic for Hebrew as the vernacular of Palestine took place very gradually. The dialect wrongly called "Chaldee" is really the language of the South-Western Arameans, who were the immediate neighbours of the Jews. *See* SEMITIC LANGUAGES.

CHALDER or **CHALDRON**, an old dry measure of capacity, usually called chalder in Scotland and chaldron in England. In Scotland the chalder was equivalent to 16 bolls (*q.v.*) of corn, and was used in computing the stipends of parish ministers, but, like the chaldron, it varied according to the locality and the commodity measured. As a measure for lime and coal, the chalder and the chaldron vary from 32 bushels upwards, and are in general equivalent in weight to about 25½ cwt.

CHALET, a term applied to the timber houses of Switzerland, the Bavarian Alps, Tirol and the French Alps. The chalet is distinguished above all by the frank and interesting manner in which it makes use of its material, wood. The timber used is generally in heavy planks, from 3 to 6in. thick, and carefully framed together somewhat in the manner of a log-house. Side walls, generally low, often project beyond the ends, forming porches or loggias, closed at the ends. Upper floors, almost universally, project over the storeys below, with all sorts of fantastic

BY COURTESY OF BURTON HOLMES

CHARACTERISTIC CHALET IN THE TIROL

and interesting bracket treatments. Balconies across the front are common and are frequently enriched with carved railings. Windows are small and hung as casements. In general, roofs are of low pitch and project enormously, both at the eaves and at the gable ends, which are occasionally snubbed with a small triangle of sloping roof at the top. The roof surfaces are covered with large wood shingles, slabs of slate or stone; in the wilder districts planks are often laid over the roof covering and weighted with

boulders to prevent damage from heavy gales. In plan, the chalet tends towards the square; frequently, not only the house proper, but stables and storage barns are included under one enormous roof. Many local peculiarities of detail exist. (*See* HOUSE.)

CHALIAPIN, FYODOR IVANOVICH (1873–1938), (shąhl-yah'pēn) Russian bass singer, born at Kazan, on Feb. 1, 1873. His early career was a varied and adventurous one; he was by turns porter, shoemaker, hunter and street sweeper. He received his first musical training as a choirboy at Kazan, but his serious studies as a singer were made under Oussatov at Tiflis, where he made his first appearance in opera in 1892 in *A Life for the Tsar*. He then sang in 1894 at the Summer theatre, St. Petersburg (Leningrad), and later at the Imperial opera house. After visiting Milan he took important parts in the Mamantoff opera company, and at a private opera house in Moscow in 1896. In 1913, during the Russian opera season organized by Sir Thomas Beecham at Drury Lane, London, he appeared in *Boris Godunov, Ivan the Terrible,* and *La Khovantchina*. His superb bass voice and remarkable dramatic powers took his audience by storm, and he had a similar success in *Prince Igor*. During the World War and afterwards, until 1921, he remained in Russia. His first appearance outside Russia after the war was at the Albert Hall, London, in 1921. He visited America in 1908; his second tour there was in 1922–23. Among his most famous parts may be named those of Ivan the Terrible in Rimsky-Korsakov's *Maid of Pskof*; Salieri in *Mozart and Salieri;* Leporello in *Don Giovanni;* Don Basilio in the *Barber of Seville;* and Mephisto in *Mefistofele*.

See his *Pages from my Life* (1927).

CHALICE, the cup used in the celebration of the Eucharist (*q.v.*). For the various forms which the chalice so used has taken, *see* DRINKING VESSELS. The ancient custom of mixing water with wine in the Eucharistic service, practised from early times in both Eastern (except the Armenian) and Western Churches, is known as that of the "mixed chalice." The practice has been generally discontinued since the Reformation in the English Church, but is not illegal if it is not done ceremonially (*Martin* v. *Mackonochie,* 1868, L.R. 2 P.C. 365; *Read* v. *Bp. of Lincoln,* 1892, A.C. 664).

CHALIER, MARIE JOSEPH (1747–1793), French revolutionary, became a partner in a business firm at Lyons for which he travelled in the Levant, in Italy, Spain and Portugal. He became the orator and leader of the Jacobins of Lyons, and induced the other revolutionary clubs and the commune of the city to arrest a great number of Royalists in the night of Feb. 5, 1793. The mayor, supported by the national guard, opposed this project. Chalier demanded of the Convention the establishment of a revolutionary tribunal and the levy of a revolutionary army at Lyons. The Convention refused, and the anti-revolutionary party, encouraged by this refusal, took action. On May 29–30, 1793, the sections rose; the Jacobins were dispossessed of the municipality and Chalier arrested. On July 15, in spite of the order of the Convention, he was brought before the criminal tribunal of the Rhone-et-Loire, condemned to death, and guillotined the next day.

See N. Wahl, "Etude sur Chalier," in *Revue historique,* t. xxxiv.; and *Les Premières Années de la Révolution à Lyon* (1894).

CHALK is a white or greyish, loosely coherent kind of limestone rock, composed almost entirely of the calcareous remains of minute marine organisms (foraminifera, cocoliths, etc.) and fragments of shells. The purest kinds contain up to 99% of calcium carbonate in the form of the mineral calcite. Silica is always present in small amounts as the mineral opal, representing the remains of other minute marine organisms and sponge spicules. Minute grains of quartz, felspar, zircon, rutile and other minerals are also present. With the admixture of clayey material there may be an insensible gradation from pure chalk to chalk-marl. Not only may there be considerable variation in the composition of chalk (phosphatic, glauconitic, etc.) but there may also be wide variations in the colour (snow-white, grey, etc.) and the texture of the material. It may be soft, incoherent and porous or quite hard and crystalline.

The uses of chalk are numerous; for example, as a writing material in the form of white and coloured crayons, for the manufacture of quicklime, mortar, Portland cement (*see* CEMENT), plaster and as a fertilizer.

Whiting is prepared by grinding chalk and collecting the finer sediments from water; this is used for polishing, making putty and many other purposes. Under the name of "paris white," chalk is used in the manufacture of india-rubber goods, oilcloth, wallpaper, etc. The harder kinds are extensively used as a building stone.

Large quantities of chalk are quarried in England in Kent, Surrey, Sussex, Cambridgeshire, Lincolnshire and Hampshire, Kent being by far the most important.

In the United States there are extensive beds of chalk in Kansas, Arkansas and Texas.

CHALKHILL, JOHN (fl. 1600?), English poet. Two songs by him are included in Izaak Walton's *Compleat Angler,* and in 1683 appeared "Thealma and Clearchus. A Pastoral History in smooth and easie Verse. Written long since by John Chalkhill, Esq., an Acquaintant and Friend of Edmund Spencer," together with a preface written five years earlier by Walton. Another poem, "Alcilia, Philoparthens Loving Follie" (1595, reprinted in vol. x. of the *Jahrbuch des deutschen Shakespeare-Vereins*), was at one time attributed to him. Nothing further is known of the poet, but a person of his name occurs as one of the coroners for Middlesex in the later years of Queen Elizabeth's reign. Professor Saintsbury, who included *Thealma and Clearchus* in vol. ii. of his *Minor Poets of the Caroline Period* (Oxford, 1906), points out a marked resemblance between his work and that of William Chamberlayne.

CHALKING THE DOOR, a former Scottish custom of tenant eviction within burgh. The law was that "a burgh officer, in presence of witnesses, chalks the most patent door 40 days before Whit Sunday, having made out an execution of 'chalking,' in which his name must be inserted, and which must be subscribed by himself and two witnesses." This ceremony proceeded simply on the verbal order of the proprietor. The Removal Terms (Scotland) Act 1886 introduced, as optional to "chalking," the procedure of giving notice to remove by registered letter posted to the last known address of the tenant. The Sheriff Courts (Scotland) Act 1907 requires written notice of removal to be given to the tenant as a prerequisite of ejection, and "chalking the door" is now an obsolete practice.

CHALLEMEL-LACOUR, PAUL AMAND (1827–1896), French statesman, was born at Avranches on May 19, 1827. Educated at the École Normale Supérieure, he became professor of philosophy at Pau and at Limoges, but was obliged to leave France after the coup d'état of 1851. He settled in Zürich, where he became professor of French literature in 1856. Three years later the amnesty permitted his return to France. Appointed by the government of national defence prefect of the Rhone in 1870, he suppressed the communard rising at Lyons directed by Bakunin. He became a deputy to the National Assembly in 1872, and in 1876 a member of the Senate. Though Challemel-Lacour sat at first on the extreme Left, he modified his opinions as time went on, and towards the close of his career was a foremost representative of moderate republicanism. He was French ambassador at Berne (1879), London (1880), minister of foreign affairs in the Jules Ferry cabinet (for some months in 1883), vice-president of the Senate (1890), president of the Senate (1893). His close and reasoned eloquence made him one of the most conspicuous members of the Senate. He died in Paris on Oct. 26, 1896.

See *Oeuvres oratoires de Challemel-Lacour* (1897) and *Études et 'exions d'un Pessimiste* (1901), edited by J. Reinach. *See* also H. Defasse, *Challemel-Lacour*.

CHALLENGE: *see* DUEL.

"CHALLENGER" EXPEDITION. The scientific results of several short expeditions between 1860 and 1870 encouraged the commissioning of a vessel for a prolonged cruise for oceanic exploration. H.M.S. "Challenger," a wooden corvette of 2,306 tons, under Captain (afterwards Sir) George Nares with a scientific staff under Prof. (afterwards Sir) C. Wyville Thomson as director, was sent out in Dec. 1872. The staff included John

Murray (afterwards Sir) and H. N. Moseley, biologists; Dr. von Willemoes-Suhm, Commander Tizard and J. Y. Buchanan, chemist and geologist. The Atlantic was crossed several times. From Cape Town south-east and east the ship visited the various islands between 45° and 50° S., reached Kerguelen island in Jan. 1874, and proceeded south about the meridian of 80° east. She was the first steamship to cross the Antarctic Circle; early in March she made for Melbourne. Thence the route led by New Zealand, the Fiji islands, Torres strait, the Banda sea, and the China sea to Hongkong. The western Pacific was then explored northward to Yokohama, after which the "Challenger" struck across the ocean by Honolulu and Tahiti to Valparaiso. She then coasted south, penetrated the Straits of Magellan, touched at Montevideo, recrossed the Atlantic by Ascension and the Azores, and reached Sheerness in May 1876. The *"Challenger" Report* was issued in 50 volumes (London, 1880–95), mainly under Sir John Murray, who succeeded Wyville Thomson in 1882.

See also Lord G. Campbell, *Log Letters from the "Challenger"* (1876); W. J. J. Spry, *Cruise of H. M. S. "Challenger"* (1876); Sir C. Wyville Thomson, *Voyage of the "Challenger," The Atlantic, Preliminary Account of General Results* (1877); J. J. Wild, *At Anchor; Narrative of Experiences afloat and ashore during the Voyage of H.M.S. "Challenger"* (1878); H. N. Moseley, *Notes by a Naturalist on the "Challenger"* (1879).

CHALLIS, a light, all-wool fabric of almost gossamer texture used for women's dressing gowns and children's suits and dresses. Challis is distinguished from all the other muslin-delaine weaves, of which class it is a member, by the tiny romantic designs in which it is printed. These designs are mostly of 18th and 19th century inspiration and show conventionalized versions of dots, rose buds, violets and other flowers.

CHALLONER, RICHARD (1691–1781), English Roman Catholic prelate, was born at Lewes, Sussex, on Sept. 29, 1691, and educated at the English college at Douai, where he was ordained a priest in 1716, took his degrees in divinity, and was appointed professor in that faculty. In 1730 he was sent to London. The controversial treatises which he published in rapid succession attracted much attention, particularly his *Catholic Christian Instructed* (1737), with its witty reply to Dr. Conyers Middleton's *Letters from Rome, showing an Exact Conformity between Popery and Paganism.* In 1741 Challoner was raised to episcopal dignity at Hammersmith and nominated coadjutor with right of succession to Bishop Benjamin Petre, vicar-apostolic of the London district, whom he succeeded in 1758. He died on Jan. 12, 1781. Bishop Challoner was the author of numerous controversial and devotional works, including the *Garden of the Soul* (1740?), one of the most popular manuals of devotion. He re-edited the Douai Bible (1749–1750), correcting the obsolete language and orthography. Of his historical works the most valuable is his *Memoirs of Missionary Priests and other Catholicks of both Sexes who suffered Death or Imprisonment in England on account of their Religion, from the year 1577 till the end of the reign of Charles II.* (1741, latest ed., 1924) intended as an antidote to Foxe's martyrology. He also published anonymously, in 1745 *Britannia Sancta,* or lives of the British saints, now superseded by that of Alban Butler.

See E. H. Burton, *Life and Times of Bishop Challoner* (1909).

CHALMERS, ALEXANDER (1759–1834), Scottish writer, was born in Aberdeen on March 29, 1759, and died in London on Dec. 19, 1834. He was educated as a doctor, but gave up this profession for journalism, and he was for some time editor of the *Morning Herald.* Besides editions of the works of Shakespeare, Beattie, Fielding, Johnson, Warton, Pope, Gibbon and Bolingbroke, he published *A General Biographical Dictionary* in 32 vols. (1812–17); a *Glossary to Shakespeare* (1797); an edition of Steeven's *Shakespeare* (1809); and the *British Essayists,* beginning with the *Tatler* and ending with the *Observer,* with biographical and historical prefaces and a general index.

CHALMERS, GEORGE (1742–1825), Scottish antiquarian and political writer, was born at Fochabers, Moray, and emigrated to Maryland in 1763, where he practised as a lawyer until the outbreak of the war of American Independence, when he returned to England. In 1786 he was appointed chief clerk to the privy council, an office which he held until his death in London May 31 1825.

Of some 30 works which he wrote the most important are *Political Annals of the present United Colonies from their Settlement to the Peace of 1763* (1780), drawn from the American State papers, and *Caledonia, An Account, Historical and Topographical, of North Britain* (1807–24). Neither of these is complete. Of the *Political Annals* only one volume was published, bringing the history down to 1688; and *Caledonia* covers only the southern counties of Scotland.

Chalmers wrote biographical sketches of Defoe, Allan Ramsay, Sir David Lyndsay, and others, prefixed to their collected works, and a *Life of Mary Queen of Scots* (1818). He engaged in many literary and historical controversies with Malone, Steevens, Dr. Jamieson, and others.

CHALMERS, GEORGE PAUL (1836–1878), Scottish portrait and landscape painter, was born at Montrose and studied at Edinburgh. The best of his works are "The End of the Harvest" (1873), "Running Water" (1875), and "The Legend" (in the National Gallery, Edinburgh). He became an associate (1867) and a full member (1871) of the Royal Scottish Academy.

CHALMERS, JAMES (1841–1901), Scottish missionary to New Guinea, was born at Ardrishaig in Argyll. He was appointed to Rarotonga in the South Pacific in 1866. After ten years' service he was transferred to New Guinea. Chalmers did much to open up the island, and, with his colleague W. G. Lawes, gave valuable aid in the British annexation of the south-east coast of the island. On April 8, 1901, in company with a brother missionary, Oliver Tomkins, he was killed by cannibals at Goaribari island. R. L. Stevenson has left on record his high appreciation of Chalmers's character and work.

See his *Autobiography and Letters* (1902).

CHALMERS, THOMAS (1780–1847), Scottish divine, was born at Anstruther, Fifeshire, on March 17, 1780. In 1799 he was licensed by the St. Andrews presbytery. After further study at Edinburgh he became assistant to the professor of mathematics at St. Andrews, and was ordained as minister of Kilmany, Fifeshire. In 1808 he published an *Inquiry into the Extent and Stability of National Resources,* a contribution to the discussion created by Bonaparte's commercial policy. His article on "Christianity" in the *Edinburgh Encyclopaedia* enhanced his reputation as an author. In 1815 he became minister of the Tron church, Glasgow, and his repute as a preacher spread throughout the United Kingdom. A series of sermons on the relation between discoveries of astronomy and the Christian revelation was published in Jan. 1817, and within a year nine editions and 20,000 copies were in circulation. When he visited London Wilberforce wrote, "all the world is wild about Dr. Chalmers."

In Sept. 1819 he became minister of the church and parish of St. John where he was singularly successful in dealing with the problem of poverty. When he undertook the management of the parish its poor cost the city £1,400 per annum, and in four years, the expenditure was reduced to £280 per annum. In 1823, after eight years of work at high pressure he was glad to accept the chair of moral philosophy at St. Andrews, the seventh academic offer made to him during the eight years spent in Glasgow. In Nov. 1828 he was transferred to the chair of theology in Edinburgh.

In 1826 he published a third volume of the *Christian and Civic Economy of Large Towns,* a continuation of work begun at St. John's, Glasgow. In 1832 he published a *Political Economy,* and in 1833 appeared his Bridgwater treatise on *The Adaptation of External Nature to the Moral and Intellectual Constitution of Man.* In 1834 he became leader of the evangelical section of the Scottish Church in the general assembly. In 1841 the movement which ended in the Disruption was rapidly culminating, and Dr. Chalmers found himself at the head of the party which stood for the principle that "no minister shall be intruded into any parish contrary to the will of the congregation." Cases of conflict between the Church and the civil power arose in Auchterarder, Dunkeld and Marnoch; and when the courts made it clear that the Church, in their opinion, held its temporalities on condition of

rendering such obedience as the courts required, the Church appealed to the Government for relief. In Jan. 1843 the Government put a final and peremptory negative on the Church's claims for spiritual independence. On May 18, 1843, 470 clergymen withdrew from the general assembly and constituted themselves the Free Church of Scotland, with Dr. Chalmers as moderator. He had prepared a sustentation fund scheme for the support of the seceding ministers, and this was at once put into successful operation. He himself became principal of the newly founded Free Church college, Edinburgh. On May 30, 1847 immediately after his return from the House of Commons, where he had given evidence as to the refusal of sites for Free Churches, by Scottish landowners, he was found dead in bed.

Dr. Chalmers' writings are a valuable source for argument and illustration on the question of Establishment. They run to 38 volumes concerned with theology, devotional practice and social economy. The most important of them is his *Institutes of Theology* written in his later years at the Free Church college.

BIBLIOGRAPHY.—W. Hanna *Memoirs* (Edinburgh, 1849–52); *Correspondence* (1853); and *Lives* by E. B Ramsay (3rd ed. 1867); D. Fraser (1881); Mrs. Oliphant (1893) and W. G. Blaikie (1896).

CHALONER, SIR THOMAS, the elder (1521–1565), English diplomatist and poet, the son of Roger Chaloner, a mercer of London, was educated at Oxford and Cambridge. In 1540 he went as secretary to Sir Henry Knyvett to the court of Charles V, whom he accompanied in his expedition to Algiers in 1541. In 1547 Chaloner served in the expedition to Scotland, and was knighted after the battle of Pinkie, by the protector Somerset. He was a witness against Bishop Bonner, in 1549, and against Stephen Gardiner, bishop of Winchester, in 1551. He was sent on missions to Scotland in 1551, 1552 and 1555–56; on an embassy to France in 1553; and under Elizabeth was resident ambassador in the Netherlands (1558–60) and Spain (1561–64). He returned home in 1564, and died at Clerkenwell on Oct. 14, 1565.

Chaloner's most important works are "How King Richard the Second was for his evil governance deposed" printed in the first, 1559, edition of William Baldwin's *Mirror for Magistrates*, best ed by Lily B. Campbell (Cambridge, 1938); *De Rep. Anglorum instauranda libri decem*, published by W. Mallim (1579); and *The Praise of Folly, Moriae encomium . . . by Erasmus . . . Englished by Sir Thomas Chaloner, Knight* (1549; ed. Janet E. Ashbee, London, 1901).

CHÂLONS-SUR-MARNE, a town of northeastern France, capital of the department of Marne, 107 mi. E. of Paris on the main line of the Eastern railway to Nancy and 45 mi. S.E. of Reims. Pop. (1946) 31,120. The town proper is bordered on the west by the lateral canal of the Marne and is traversed by branches of the canal and by small streams.

Châlons-sur-Marne occupies the site of the chief town of the Catalauni and, on the plain between it and Troyes, Attila was defeated by the Romans in 451. In the 10th and following centuries it attained great prosperity under its bishops, who were ecclesiastical peers of France. In 1214 the militia of Châlons served at the battle of Bouvines; and in the 15th century the citizens twice repulsed the English from their walls. In the 16th century the town sided with Henry IV., king of France, who in 1589 transferred thither the parliament of Paris, which shortly afterwards burnt the bulls of Gregory XIV. and Clement VIII. The camp of Châlons, about 16 m. N. of the town, was established in 1856 by Napoleon III. and is a training-centre for troops. Châlons was occupied by the Germans in August, 1914, and was retaken by Foch in September, 1914. The cathedral of St. Étienne (chiefly 13th century) has a 17th century west façade. There are stained-glass windows of the 13th century in the north transept. Notre-Dame, of the 12th and 13th centuries, is conspicuous for its four Romanesque towers, two flanking the apse, two flanking the principal façade. The churches of St. Alpin, St. Jean and St. Loup date from various periods between the 11th and 17th centuries. The hôtel-de-ville (1771), the prefecture (1759–1764), the college, once a Jesuit establishment, and a training college which occupies the Augustinian abbey of Toussaints (16th and 17th centuries), are noteworthy civil buildings. The houses are generally ill-built, but some old mansions remain. The town is the seat of a bishop and a prefect, has tribunals of first instance and of commerce, a chamber of commerce, a board of trade-arbitrators, a museum and a library. The principal industry is brewing, which is carried on in the suburb of Marne. Galleries hewn in a limestone hill are used as store-houses for beer. The preparation of champagne, the manufacture of boots, brushes, wire-goods and wall-paper also occupy many hands. There is trade in cereals. (X.)

Battle of Châlons.—The battle of the Catalaunian Plains, "fierce, manifold, huge, stubborn, without its like in the history of times past" (Priscus), was fought between Attila and the Roman Aëtius in 451 A.D.

The Huns had crossed the Danube in the first quarter of the fifth century. Uldin, their leader was driven back by the soldiers of Byzantium; but by 424 the Byzantine court was paying the Huns a tribute of 350lb. of gold. Some ten years later Attila, nephew of a king who had brought the Huns to some rough unity of predatory purpose, became joint ruler with his brother. Attila, a typical Kalmuck in appearance, thereupon began a career of plunder. In another ten years he had forced the eastern empire to multiply sixfold the annual tribute. In six more years he had become lord of the lands north of the middle and lower Danube, and wasted the northern Balkan country. He forbade his Huns and Germans subject to him to take service in the imperial armies. The western Roman armies had long ceased to find their soldiers from within the frontiers; therefore Attila could cut off one of the main supplies of men.

Aëtius had been no enemy of the Huns, and had used them to make an end of the Burgundian kingdom about Worms (whence the Nibelungenlied). In 450 a good soldier, Marcian, became emperor of the East, and refused to pay the Hunnic tribute. A few months earlier a discontented Roman princess had given Attila a pretext for turning to that quarter of the world which he had not yet plundered. Justa Gratia Honoria, sister of the emperor Valentinian III. had plotted with a lover to take the throne. The plot was discovered; Honoria was married to a respectable and harmless senator. Honoria boldly sent to Attila for help, with her ring to show from what quarter the message came. Attila took the ring to mean that Honoria would be his wife. The time was good for using this claim; Gaiseric, king of the Vandals, fearing an attack from the Visigoths in southwest Gaul, had asked for Attila's alliance.

In 451 Attila led into Gaul a host of Huns, Alans and tributary Germans. Two parties were disputing the kingship of the Franks on the Rhine; one group joined the Huns, and thereby decided Attila's route. On April 7 this host plundered Metz, and thence moved slowly towards Orleans. Aëtius had not crossed the Alps in time to hold the Rhine; nor could he do much without Visigothic help. The fall of Orleans would leave the way open across the Loire to the Visigothic lands; therefore the Visigoths listened to Aëtius' messengers. An army of Romans (that is, of Romanized Germans) and Visigoths marched to save Orleans. Legends of the prowess of a Christian bishop (the legend of St. Geneviève is of the same time) have clouded over the history of the attack upon Orleans. But the town was on the point of falling when Aëtius and Theodoric, the Visigothic king, forced the Huns to retire.

Attila took the road northwards to Troyes and collected his forces on the plains well fitted for his cavalry. Chalons has been named as the chosen battlefield; but the *campi Catalaunici* include most of Champagne. The best chroniclers speak of a certain "Mauriac place." There was a Moirey west of Troyes, and there is a Méry-sur-Seine where bones, weapons and gold ornaments have been found. Here, about sixteen miles north-west of Troyes, some scholars think must be the "Mauriac place" and the tomb of Theodoric. On the night before the battle those Franks who favoured Aëtius broke through to him after a slaughter of 15,000 men. Before the day began Attila took the voice of his augurs; the Huns would be beaten (a likely prophecy about a retreating tribal host), but the enemy leader would fall. Attila could get another army; the empire had not another Aëtius, nor would anyone else be likely to keep together the Visigoths and Romans. By delaying until 3 P.M. Attila planned to secure

his retreat in the darkness. The chroniclers say that on one side the field sloped towards a slight hill; for this hill the armies fought. In the place of honour on the Roman right were the Visigoths; on the left Aëtius, and with him as a hostage, Thorismund son of Theodoric; in the centre, enclosed by more trusted troops were the Alan auxiliaries of the Romans. Aëtius hoped that the Huns might try to drive in this centre, for Attila kept in the midst of his Huns, and set the Ostrogoths and Gepidae on the left, and on his right the lesser German allies. Here was the decision. Aëtius seized the hill; his Alans were forced back, but now he could take the Huns on one flank, while on the other the Visigoths attacked. Thus the victory in this last great battle of western Roman power was won by the tactics which Hannibal had used at Cannae.

The Huns expected another attack, since in the immense slaughter Theodoric had been killed but Aëtius was alive. Attila, within his ring of wagons, prepared for death; but Aëtius feared a camp of desperate men whose strength was in their archery. Nor was he willing to secure in Gaul a Visigothic predominance against which the Huns might yet be his allies. He persuaded Thorismund to hasten to Toulouse, lest his brothers should take his inheritance. Attila escaped to ravage Italy in 452, and to die, or be murdered in a drunken sleep in 453. Was this battle of the "Mauriac place," one of the world's decisive battles? The Huns showed nothing of the fruitfulness of the Germanic peoples who came within the Empire, and their power could scarcely have survived for long the death of a king who was as rare as a Saladin among the Kurds. A son of Attila and Honoria might have been another Aëtius, if Attila's other sons had not put him to death; but the coming of the Huns was only an episode before the greater confusion of the dark ages, before the victory of Charles Martel, and the splendour and dominion of Charlemagne.

(E. L. W.)

CHALON-SUR-SAÔNE, an industrial town of east-central France, capital of an arrondissement in the department of Saône-et-Loire, 81 mi. N. of Lyons by the P.L.M. railway. Pop. (1946) 37,083. It is a well-built town, with fine quays, situated on the right bank of the Saône at its junction with the Canal du Centre. A 15th century bridge with 18th century obelisks, leads to the suburb of St. Laurent on an island in the river. Chalon-sur-Saône is identified with the ancient *Cabillonum,* an important town of the Aedui. It was chosen in the 6th century by Gontram, king of Burgundy, as his capital. The bishopric, founded in the 4th century, was suppressed at the Revolution. In feudal times Chalon was the capital of a countship. In 1237 it was given in exchange for other fiefs in the Jura by Jean le Sage, whose descendants nevertheless retained the title. Hugh IV, duke of Burgundy, the other party to the exchange, gave the citizens a communal charter in 1256. The town resisted a division of the Austrian army in 1814.

The church of St. Vincent, once the cathedral, dates mainly from the 12th to the 15th centuries, and has a choir in the 13th century Burgundian style. The old bishop's palace dates from the 15th century. The church of St. Pierre, with two lofty steeples, is late 17th century. Chalon preserves remains of its ancient ramparts and a number of old houses. It is the seat of a sub-prefect and a court of assizes, and has tribunals of first instance and commerce and a chamber of commerce. Chalon ranks next to Le Creusot among the manufacturing towns of Burgundy. Its position at the junction of the Canal du Centre and the Saône, and as a railway centre for Lyons, Paris, Dole, Lons-le-Saunier and Roanne, brings it a large transit trade. The founding and working of copper and iron are its main industries; the large engineering works of Petite-Creusot, a branch of those of Le Creusot, construct bridges, tug-boats etc., and there are chemical works, straw-hat factories, oil-works and tile-works. It is a busy corn-market and trades widely in wine, grain and timber.

CHALUKYA, the name of an Indian dynasty which ruled in the Deccan from A.D. 550 to 750, and again from 973 to 1190. The Chalukyas claimed to be Rajputs from the north. The dynasty was founded by a chief named Pulakesin I, who mastered the town of Vatapi (now Bādāmī, in the Bijapur district) about 550. His sons extended their principality east and west; but the founder of the Chalukya greatness was his grandson Pulakesin II, who succeeded in 608 and established as his viceroy in Vengi (609) his brother Kubja Vishnuvardhana, who in 615 declared his independence and established the dynasty of Eastern Chalukyas, which lasted till 1070. In 620 Pulakesin defeated Harsha (*q.v.*), the powerful overlord of northern India, and established the Nerbudda as the boundary between the South and North. He also defeated in turn the Chola, Pandya and Kerala kings, and by 630 was beyond dispute the most powerful sovereign in the Deccan. In 655 the Chalukya power was restored by Pulakesin's son Vikramaditya I.; but the struggle with the Pallavas continued until, in 740, Vikramaditya II. destroyed the Pallava capital. In 750 Vikramaditya's son, Kirtivarman Chalukya, was overthrown by the Rashtrakutas.

In 973, Taila or Tailapa II. (d. 995), a scion of the royal Chalukya race, succeeded in overthrowing the Rashtrakuta king Kakka II. He was the founder of the dynasty known as the Chalukyas of Kalyani. About A.D. 1000 a formidable invasion by the Chola king Rajaraja the Great was defeated, and in 1052 Somesvara I., or Ahamavalla (d. 1068), the founder of Kalyani, defeated and slew the Chola Rajadhiraja. The reign of Vikramaditya VI., or Vikramanka, which lasted from 1076 to 1126, formed another period of Chalukya greatness. In 1156 the commander-in-chief Bijjala (or Vijjana) Kalachurya revolted, and he and his sons held the kingdom till 1183, when Somesvara IV Chalukya recovered part of his patrimony, only to succumb, *c.* 1190, to the Yadavas of Devagiri and the Hoysalas of Dorasamudra. Henceforth the Chalukya rajas ranked only as petty chiefs.

Smith, *Early History of India,* ed. by S. M. Edwardes (Oxford, 1924); D. C. Ganguly, *The Eastern Cālukyas* (Benares, 1937).

CHALUMEAU is a word having several different musical meanings (from Lat. *calamus,* a reed). Thus it is the name of an obsolete wind instrument, with a single beating reed, of the clarinet type; and also of a later instrument, with a double reed, which developed into the oboe. It is used also for the deepest notes of the clarinet and further, in its German form of Schalmey or Schalmei, for the chanter of the bag-pipe and for an old kind of organ stop of chalumeau-like quality.

CHALYBÄUS, HEINRICH MORITZ (1796–1862), German philosopher, was born at Pfaffroda in Saxony. He lectured at Dresden on the history of German philosophy, and in 1839 became professor in Kiel university. His first published work *Historische Entwickelung der spekulativen Philosophie von Kant bis Hegel* (1837, Eng. tr. 1854), still ranks among the best expositions of 19th century German thought. His chief works are *Entwurf eines Systems der Wissenschaftslehre* (Kiel, 1846) and *System der spekulativen Ethik* (1850).

See Überweg, *Grundriss der Gesch. der Philosophie,* Bd. iv. (1923).

CHALYBITE: *see* SIDERITE.

CHAM, a Muslim tribe of Indo-China, rather dark skinned with Oceanic affinities, practising circumcision but with strong traces of Hinduism, phallic worship and animism surviving in their beliefs and customs. Thus they believe in a plurality of souls, eighteen of which are mortal, attached to each individual, and associate the departure of the soul at death with the flight of a bird. They bury their dead close to their best rice fields, and have a series of ceremonies depending on the operations of the agricultural year; the reaping of the rice crop must be initiated by a woman. In the family the matrilineal system is still followed. Children are given opprobrious names, probably to obviate the malice of the spirits. Speech is tabu when collecting the valuable "eagle wood" (*aquilaria agallocha*), and invulnerability is procured by anointing the body with human bile. The Cham are fond of regattas and boat races, and play chess using canoes instead of bishops. The language of the tribe is connected with Cambodian and with Oceanic tongues and, like the dolichocephaly of its speakers, and their customs, suggests an Indonesian basis for the tribe.

See Baudesson, *Indo-China and its Primitive People* (1919); Leuba, *Les Chams et leur Art* (1923).

CHAMBA, a municipality, *tehsil* (administrative subdivision) and district in Himachal Pradesh, northern India. Chamba town (pop., 1951, 6,858) is situated above the Ravi gorge.

CHAMBA TEHSIL (area 1,429 sq.mi.) had a population in 1951 of 75,970.

CHAMBA DISTRICT (area 3,135 sq.mi.; pop., 1951, 176,050) corresponds almost exactly with the former princely state of that name. The state was founded in the 6th century: it was sometimes subject to Kashmir and later to the Mogul empire, but was always in practice autonomous. It was brought under British influence and declared independent of Kashmir in 1846; and was controlled under British paramountcy through the Punjab agency (Lahore residency). On April 15, 1948, it was merged with Himachal Pradesh, forming that state's isolated northwestern tract. The district is wholly mountainous, reaching above the snowline in east, north and centre.

CHAMBER, THE KING'S, the *camera regis*, was, in the later middle ages, an important financial office. In origin it was the king's bedroom, with cupboards and chests for clothes and valuables. The servants in charge of this room, the king's chamberlains as they were called (*see* CHAMBERLAIN), were in such close touch with the king that they were often consulted and employed by him on matters not strictly within their province. Thus, the king's chamber was, from the beginning, something more than mere sleeping quarters. It was an office where the king attended to private and public business alike, the greater part of which related to finance, and a storehouse for jewels, money and archives. From it, the first department to grow up within the royal household (*q.v.*), there sprang many mediaeval and modern ministries of state. Not only in England but throughout western Europe kings and magnates had their chamber, the *chambre des comptes* of the kings of France and the *camera apostolica* of the popes being cases in point.

In England the reconstruction following on the Norman Conquest provided the monarchy with a regular income from taxation, the collection and administration of which threw upon the chamber so much extra work that it became concerned primarily with finance. A hierarchy of clerical and lay officials came into being to assist the original staff. But, whereas in Europe generally, for example in the papacy and in France, the *camera curiae*, the chamber of the court, was the sole treasury of the state, in England by the 12th century, the king's chamber had developed a branch to deal with the finances of the kingdom as opposed to the more personal finances of the king. This was the exchequer (*q.v.*), the first department of the household to become a public office. It soon superseded the chamber, which then found itself once more a simple domestic and court office, although certain moneys continued to be paid to it rather than to the exchequer. The activities of the chamber were curtailed still further in the 13th century by the growth of a second offshoot, the king's wardrobe (*see* WARDROBES), by which it was ultimately replaced as the chief financial and administrative office of the household. Yet the chamber persisted, responsible to the king alone and overlapping the jurisdiction of both exchequer and wardrobe. Though its former power had been whittled down to authority over only the intimate financial needs of the king, there were several attempts to give it a foremost position in administration. Some of them, especially those of Edward II, Edward III and Henry VII, achieved considerable success.

Faced by a hostile baronage which sometimes dominated the chief public offices and interfered in the government of the royal household, Edward II turned to the chamber to secure independence of aristocracy, parliament and exchequer. To finance it adequately he allotted to it the management and income of certain lands which fell into his hands. The forfeited estates of the Templars (*q.v.*) were the first large block of lands to be brought under the authority of the chamber (1309). In 1322 the confiscation of the possessions of certain rebellious magnates, known as the "contrariants," put into Edward's power many more lands, which were soon reserved to the chamber, although only for a few months. The chamber staff was increased to discharge the duties involved in the care of an estate, and the secret seal fostered by Edward II in opposition to the privy seal (*see* SEALS: *Small*), which the barons strove to control, was entrusted to it. In the schemes of the younger Hugh Despenser, made king's chamberlain in 1322, the chamber played a leading part, but its progress was checked by Edward II's deposition, and its lands transferred to the exchequer.

In 1332 Edward III revived the chamber on the lines indicated by Despenser, and gradually placed a large number of lands at its disposal. A special seal, the griffin (*see* SEALS: *Small*), was set up for their service and the regular staff was again augmented. Edward III's need, however, differed from that of his father. Instead of an alienated baronage to contend with, Edward III had a foreign enemy, France, against whom all parties were united Consequently he had less inducement to cultivate the chamber for purely prerogative purposes. His chamber seems to have met little unfriendly criticism, and, in the first phase of the Hundred Years' War, had a fair opportunity of proving its worth. During the early campaigns, its chief officers took a conspicuous share in administration at home as well as with the armies abroad. But the estate upon which it largely relied disappointed expectations, most of the proceeds being swallowed up by the costs of its administration. Without considerable funds the chamber was crippled. In 1355–56, therefore, the estate was given up, and for it an annual sum of 10,000 marks (£6,666, 13*s.* 4*d.*) payable by the exchequer, was substituted. This, the *certum* (fixed amount), was supplemented, as before the estate revenue had been, by casual receipts from the exchequer and elsewhere. Although the chamber was still answerable only to the king, its utility as an instrument of prerogative was diminished by this close dependence upon the exchequer. A further limitation was its total lack of skilfully devised, well-tried machinery to enforce its authority, for the griffin seal and the organization set up to administer the lands disappeared along with the estate. If, for the rest of Edward III's reign, the chamber occupied a recognized, amply endowed place in the administration, it was definitely subordinated to the exchequer. It was the royal privy purse, and a means whereby the king's will could be communicated to other departments, but little more.

On the accession of Richard II, a child with few personal expenses, the king's chamber suffered a natural relapse. When, in 1380, it was restored to something of its old dignity, the policy of 1355–56 was adopted, and a yearly allowance was granted to it, first from the customs, then, two years later, from the exchequer. On this *certum*, at most not more than two-thirds of that enjoyed under Edward III, the chamber was mainly dependent to the end of the 14th century, though in some years large casual payments were received. Such an office was valueless to a despotically minded king, and Richard II seems never to have thought of making it a chief instrument of his prerogative. Yet chamber officials figured prominently among his confidants, and it was in his reign that the office of king's secretary (*see* SECRETARY OF STATE) assumed definite shape, the final result being the withdrawal from the chamber of the secretary and his seal, the signet (*see* SEALS: *Small*), the successor to the secret seal.

Of chamber history in the greater part of the 15th century little is known, but the office lived on. Then, in the restoration of financial stability after the Wars of the Roses (*q.v.*), Henry VII advanced it to a position of supreme importance. Although he began to put the exchequer into working order, he wanted some less rigid, less elaborate machinery to supply him at once with the steady income necessary to strengthen government and throne. Like Edward II and Edward III he had recourse to the chamber as the most suitable instrument and one that was, besides, entirely in his control. Forfeited estates and crown lands were once again reserved to it, and other moneys were paid to it instead of to the exchequer. A new staff grew up, and to the daily labours of the regenerated office the king gave constant oversight. Unlike the Edwards, Henry was able to make the chamber effective, for, although he too diverted to the chamber revenues ordinarily paid and accounted for to the exchequer, and imposed

upon it functions technically belonging to the exchequer, the exchequer's extreme weakness, due to civil war, prevented remonstrance from that quarter.

Soon after the death of Henry VII., however, the exchequer, grown stronger, tried to insist that issues formerly paid to it, and accounts customarily rendered to it for audit, should still follow those rules, and not go to the chamber. In reply to this claim Henry VIII. induced parliament to recognize his father's system. Thus the chamber, already possessing wider influence than in the 14th century, seemed well on the way to recapturing its original position in the State. But Henry VIII., hard-working as he was, attended less to the routine of government than Henry VII., and the exchequer slowly deprived the chamber of all its newly given power. When the exchequer had recovered from the effects of the Wars of the Roses, not even Henry VIII. himself could maintain for the chamber the supremacy won under the guidance of Henry VII. Yet it was not until Mary's reign that the exchequer regained its traditional status, and then it was an exchequer changed at heart. From the end of the 13th century the chamber's rise and fall was chiefly determined by the weakness or strength of the exchequer. By taking over the best the chamber had to offer, the exchequer rendered it harmless for all time. There was no subsequent attempt to revive the work of that department, and only a memory of past glory is preserved in the office of the modern lord chamberlain (*q.v.*).

B.)

CHAMBERLAIN, ARTHUR NEVILLE (1869–1940), British politician, was born March 18, 1869, the son of Joseph Chamberlain by his second wife. Educated at Rugby and Mason college, Birmingham, he was successful in business in Birmingham and was lord mayor in 1915–16.

After serving on the central board of control of the liquor traffic and as director of national service during World War I., he became M.P. for the Ladywood division of Birmingham in 1918, was postmaster general from Oct. 1922 to March 1923, and then minister of health.

In Aug. 1923 he was made chancellor of the exchequer, but the government fell before he could present a budget. Again health minister in 1924, he carried out useful pension, housing and pure-food reforms. In 1931 he again became chancellor of the exchequer, retaining office until he succeeded Baldwin as prime minister in May 1937.

During his premiership, Chamberlain had to face a profound crisis in Europe, and to meet the growing might of nazi Germany. His aim was to ward off the danger of war by acquiescing in what he considered to be reasonable German demands, and this policy of appeasement reached its climax in the Munich agreement of Sept. 30, 1938, and the joint Anglo-German declaration of intention not to war on each other.

Chamberlain held that "peace in our time" was assured by this agreement, and as such augury it was hailed by his country. But Hitler's abrogation of the Munich agreement six months later with the complete absorption of Czechoslovakia proved these hopes to be illusory. Chamberlain then declared that Britain would oppose further nazi aggression by force and gave a guarantee of assistance to Poland (March 31, 1939). It was never clear how this guarantee could be made effective, however, for during the summer of 1939 the government failed to come to an agreement with Russia, the only power which could materially have helped Poland. After the Russo-German agreement of Aug. 1939, the German attack on Poland forced Chamberlain to declare war on Germany on Sept. 3, 1939.

Though essentially a peacetime leader, Chamberlain remained prime minister during the period of the "phoney" war, but the military debacle in Norway and the German attack on the Low Countries and France forced him to resign on May 10, 1940, in favour of Winston Churchill (*q.v.*). He was appointed lord president of the council and remained in the cabinet until Oct. 3, when he resigned this office and the leadership of the Conservative party because of ill-health. On Nov. 9, 1940, he died, a disillusioned man who had seen destroyed all his hopes of maintaining peace in Europe. (C. M. CL.)

CHAMBERLAIN, SIR (JOSEPH) AUSTEN (1863–1937), the eldest son of Joseph Chamberlain (*q.v.*) and of his first wife, Harriet Kenrick, was born at Birmingham on Oct. 16, 1863. He was educated at Rugby and Trinity College, Cambridge, and afterwards studied in Paris and Berlin. During the early stages of the Home Rule controversy he acted as his father's private secretary, and in 1892 was returned unopposed as M.P. for East Worcestershire. This seat he held until 1914, when, on his father's death, he succeeded him as a member for West Birmingham. "I was born in Birmingham," he said when he was given the freedom of that city in 1926. "I was bred in Birmingham; Birmingham is in my blood and in my bones, and wherever I go and whatever I am, I shall remain a Birmingham man."

His maiden speech drew from Gladstone the famous compliment, uttered in his father's presence, that it was one which must have been "dear and refreshing to a father's heart." After a short apprenticeship as a private member, he was a civil lord of the Admiralty (1895–1900), financial secretary to the Treasury (1900–2) and postmaster-general (1902). This rapid promotion was not due merely to the towering influence of his father, during the days of his great colonial secretaryship. Though the son's powers were of a solid rather than of a showy order, his administrative ability and his cogency in debate steadily developed with opportunity. His command of clear statement was exceptional; and he could be unexpectedly formidable in defence. In 1903 he was promoted to the chancellorship of the Exchequer. He ardently espoused his father's fiscal policy of tariff reform, nor did he slacken in its advocacy when Joseph Chamberlain left the Balfour administration in order to prosecute, with less embarrassment to the prime minister, his unofficial campaign. Unfriendly critics suggested at the time that the son's promotion to the second post in the Government was made in the hope of continuing his father's activities within reasonable bounds and preventing the threatened rupture in the party. This is not an adequate view. The father outside the Cabinet, like the son inside it, wished not to rupture their party but to convert it as a whole to the new doctrine of closer Imperial economic union and tariff-defence at home against foreign protection. Austen Chamberlain remained at the exchequer till the Unionist *débâcle* at the polls in 1906 and there acquired the reputation of being a departmentalist of the best Victorian type—safe, cautious, hard-working, and signally loyal to his associates. This loyalty was unflinching and more than once self-sacrificial.

During the long Liberal domination from 1906 to the World War Austen Chamberlain consolidated his position as a Unionist leader and gained the high esteem of all parties. He suffered, however, a great disappointment when Balfour, faced by the discontent and revolt of the rank and file, resigned his leadership of the Unionist party in 1911. Austen Chamberlain's claims to the succession were well supported. But a slightly stronger section favoured the claims of Walter Long, and as neither would yield to the other, both honourably agreed to the election of Bonar Law.

When the first Coalition Government was formed, in 1915, Austen Chamberlain entered Asquith's Cabinet as secretary of state for India, and held this post until 1917, when he resigned in consequence of the Government's decision to submit to a judicial investigation the charges and criticisms embodied in the report of the Mesopotamia commission. In his view the public interest and his personal honour alike required his resignation, though not one of the charges referred to him. The official responsibilities for the "horrible break-down" of the hospital arrangements during the first advance on Baghdad were incurred without his personal knowledge. His insistence on resignation was over-scrupulous, but showed that his views of what principle and loyalty demand were stricter than the normal. He did not long remain out of office. In April 1918 he became a member of the War Cabinet and after the Armistice returned to the chancellorship of the Exchequer in succession to Bonar Law. His guiding principle during the next two years was to strengthen British credit and pay off debt,

and to that end he called upon the taxpayer to make unprecedentedly heavy sacrifices, especially in respect of income tax, super-tax and excess profits duty. At the Treasury in a very British way he preserved an iron tradition of fiscal integrity.

In 1921 Bonar Law's failing health caused his withdrawal from active politics. Austen Chamberlain stepped into the vacant leadership of the House of Commons amid general acclamation. The post carried with it the virtual promise of the leadership of the Conservative party, ten years after the frustration of that chance in 1911. But the restraints and compromises of coalition had already begun to be irksome to many Conservatives, who distrusted the direction in which the Liberal prime minister of the Coalition was leading them. Austen Chamberlain, as lord privy seal and leader of the House, found that his staunch loyalty to his chief was bringing him into disfavour with many of the Conservative rank and file. The complaint was that he did not stand up to Lloyd George with sufficient firmness and that he sacrificed too many Conservative principles. This feeling was sharply intensified when Austen Chamberlain took a leading part at the end of 1921 in the startling settlement with Sinn Fein and the establishment of the Irish Free State. He pleaded boldly and eloquently for this "act of faith." He had been, indeed, the first to suggest to the prime minister that a choice had to be made between negotiations with the rebels and a thorough reconquest of Ireland.

Most of the Conservative party accepted the treaty with reluctance and with forebodings. Party confidence in Austen Chamberlain was further weakened by his steady refusal to listen to suggestions that fidelity to Conservative principles required him to lead his party out of Coalition bondage into party independence and freedom. His view, shared by his principal Conservative colleagues in the Lloyd George administration, was that Coalition was still necessary to deal with the difficult problems of the post-War period and not less to obviate the dangers of a socialist government, which, without co-operation between the two older parties, could not in their view long be averted. When, therefore, the discontented Conservative Diehards carried their revolt to success, and at the Carlton Club meeting on Oct. 19, 1922, offered the leadership to Bonar Law—who accepted it—Austen Chamberlain once more saw the ruin of his highest chances in politics. He and those of his colleagues who shared his views and quitted office with Lloyd George, naturally had no place in Bonar Law's Cabinet. He remained a private member during Baldwin's first administration and during the short period of the succeeding Labour Government. The dissensions in the Conservative party were gradually healed. When Baldwin formed his second administration, at the end of 1924, the post of foreign secretary was accepted by Austen Chamberlain. Then began a new stage of his career. Thirteen days after he entered on his duties at the Foreign Office (*i.e.*, on Nov. 20, 1924) Sir Lee Stack, governor general of the Sudan and Sirdar of the Egyptian army, was murdered in Cairo. The resultant situation was handled by Austen Chamberlain with a promptness and firmness that prevented further trouble, and at once established his own prestige as foreign secretary. Without delay he applied himself, at the beginning of 1925, to the remarkable diplomacy which produced the Locarno treaties. That diplomacy was pursued throughout the year, and it was mainly due to his moral earnestness and determination (for the sceptics abounded) that the treaties were initialled at Locarno on Oct. 16, 1925, Austen Chamberlain's birthday. For the nature of those treaties *see* LOCARNO, PACT OF. For the part he had played in this big step towards post-War reconciliation in Europe, Chamberlain received the Garter on Nov. 30, 1925 and the Nobel prize for peace in the same year (jointly with Charles G. Dawes). He increased the general pacific tendency in Europe by making the League of Nations a first consideration of his policy, himself attending all the meetings of the Council and Assembly. Germany's entry into the League in September 1926 was an event for which he personally was entitled to much credit. In 1927 his policy in the Chinese crisis was both conciliatory and strong. A military force was sent out to safeguard against possible attack and anarchy the great commercial community of Shanghai, but Great Britain also was the first in the field with proposals for large and increasing concessions to Chinese nationalism.

In May 1927 he reluctantly broke off relations with Russia after the Arcos raid, when it became clear that Bolshevism was violating normal diplomatic rules both in China and Britain. In the summer he initiated discussions with Sarwat Pasha for an Anglo-Egyptian treaty of alliance. A nine months' effort was thwarted early in 1928 by Cairo's repudiation of Sarwat and the emergence of Nahas Pasha as his successor. The failure of the three-Power naval conference at Geneva in July was not directly his responsibility. During the winter of 1927–28 and up to the summer of 1928 his general policy was concerned with a consideration of Kellogg's proposal for a Peace Pact, which he supported with some reserves as to interpretation, though wholly endorsing its principle. The Pact was duly signed in August. In the autumn of 1928 illness forced him to take a long sea voyage through the Panama Canal to California and thence through Canada homewards. His health had been rapidly restored, but in his absence the Foreign Office was widely attacked for its effort—wrapped in needless mystery—to concert with France joint suggestions to America on the subject of naval limitation. Public criticism made an end of this method, for which the Admiralty and the Cabinet generally were mainly responsible. Sir Austen died Mar. 16, 1937.

CHAMBERLAIN, CHARLES JOSEPH (1863–1943), U.S. plant morphologist and cytologist, was born near Sullivan, Ohio on Feb. 23, 1863 and educated at Oberlin college, graduating in 1888. Most of his life he was connected with the University of Chicago, from which he obtained the degree of Ph.D. in 1897 and Sc.D. in 1923. He became instructor in 1901, spent one year in Bonn, Germany where he worked in the laboratory of Prof. Eduard Strasburger, and after his return, was appointed assistant professor in 1907, associate professor in 1911 and was professor of plant morphology and cytology from 1915 until his retirement in 1931. He was fundamental in organizing botanical laboratories and was in charge of them from the beginning. His interest in morphology and life history of cycads caused him to make many exploring trips which resulted in the assembling of the most extensive and complete collection of living cycads in the greenhouses of the university. He visited Mexico in 1904, 1906, 1908 and 1910 and made a long journey in 1911–12 to New Zealand and Australia, returning through South Africa. In 1914 and 1922 he collected in Cuba. He died on Feb. 5, 1943.

His publications include *Morphology of Spermatophytes* (1901); *Morphology of Angiosperms* (1903) *and Morphology of Gymnosperms* (1910, ed. 2, 1917) all in collaboration with J. M. Coulter; among his other works are *Methods in Plant Histology* (1901, ed. 5, 1932) and *Gymnosperms, Structure and Evolution* (1935).

See *Bot. Gaz.*, vol. civ (1943) and *Chronica Botanica*, vol. vii (1943).

CHAMBERLAIN, JOSEPH (1836–1914), British statesman, third son of Joseph Chamberlain, master of the Cordwainers' Company, was born at Camberwell Grove, London, on July 8 1836. His father carried on the family business of boot and shoe manufacture, and was a Unitarian in religion and a Liberal in politics. Young Joseph Chamberlain was educated at Canonbury (1845–50), and at University college school, London (1850–52). After two years in his father's office in London, he was sent to Birmingham to represent his father's interest in the firm of Nettlefold, screw manufacturers. Nettlefold and Chamberlain employed new inventions and new methods of attracting customers. After years of success Chamberlain himself, with daring but sure ability amalgamated rival firms so as to reduce competition. In 1874 he was able to retire with an ample fortune. Taking a more and more important part in the municipal and political life of Birmingham, in 1868 when the Birmingham Liberal Association was reorganized, he became one of its leading members. In 1869 he was elected chairman of the executive council of the new National Education League. He took an active part in education, started classes for his workmen, and himself taught history, French and arithmetic in a Unitarian Sunday school. In 1869 he was elected a member of the town council. He married in 1868 his first wife's cousin, Florence Kendrick (d. 1875).

In 1870 he was elected a member of the first school board for Birmingham; and for the next six years, and especially after 1873, when he became leader of a majority and chairman, he actively championed the Nonconformist opposition to denominationalism. He was then regarded as a republican—the term signifying rather that he held advanced Radical opinions, which were construed by average men in the light of the current political

developments in France, than that he really favoured republican institutions for Britain. His programme was "free Church, free land, free schools, free labour." At the general election of 1874 he stood as a parliamentary candidate for Sheffield, but without success. Between 1869 and 1873 he worked in the Birmingham town council for the realization of the projects of municipal reform preached by Dawson, Dr. Dale and Bunce (of the "Birmingham Post"). In 1873 his party obtained a majority, and he was elected mayor, an office he retained by re-election until June 1876. As mayor he had to receive the prince and princess of Wales on their visit in June 1874, an occasion which excited some curiosity because of his reputation as a republican; but the behaviour of the Radical mayor satisfied the requirements alike of *The Times* and of *Punch*.

Birmingham.—The period of his mayoralty was important for Birmingham itself, and the stupendous energy which Chamberlain brought to bear on evil conditions in Birmingham had repercussions in every municipality in the country. The conference of local sanitary authorities summoned by him in 1874 and held in Jan. 1875 was the beginning of the modern movement for better and healthier organization of town life. In Birmingham he carried through the municipalization of the supply of gas and water, and the improvement scheme by which slums were cleared away and 40 acres laid out in new streets and open spaces. New municipal buildings were erected, Highgate park was opened for recreation, and the free library and art gallery were developed. The prosperity of modern Birmingham dates from 1875 and 1876, when these admirably administered reforms were initiated, and by his share in them Chamberlain became not only one of its most popular citizens but also a man of mark outside. An orator of a practical but consummate type, cool and hard-hitting, his spare figure, incisive features and single eye-glass soon made him a favourite subject for the caricaturist; and in later life his aggressiveness made his actions and speeches the object of more controversy than was the lot of any other politician of his time. In private life his loyalty to his friends, and his "genius for friendship" (as John Morley said) made a curious contrast to his capacity for arousing the bitterest political hostility. It may be added here that the interest taken by him in Birmingham remained undiminished during his life, and he was the founder of Birmingham university (1900), of which he became chancellor.

In 1876 Dixon resigned his seat in parliament, and Chamberlain was returned for Birmingham in his place unopposed, as John Bright's colleague. He made his maiden speech in the House of Commons on Aug. 4, 1876, on Lord Sandon's education bill. At this period, too, he paid much attention to the question of licensing reform, and in 1876 he examined the Gothenburg system in Sweden, and advocated a solution of the problem in England on similar lines. During 1877 the new federation of Liberal associations, which became known as the "Caucus," was started under Chamberlain's influence in Birmingham, the results of which were clearly shown in the general election of 1880.

After the general election of 1880 the Liberal party numbered 349 against 243 Conservatives and 60 Irish Nationalists. Gladstone was compelled to recognize the services of the Radicals in the election by the inclusion of Dilke and Chamberlain, who were sworn allies, in the new ministry. They had resolved together that one of them must be in the cabinet. The prime minister had not contemplated the admission of either, and was determined not to have both. Chamberlain, willing to give the preference to Dilke, was himself chosen as president of the Board of Trade. Dilke became under-secretary for foreign affairs but, at the end of 1882, he too entered the cabinet as president of the Local Government Board, and the alliance between the two rising ministers was more powerful than ever. The position of the Radicals in the 1880–85 Government was extremely difficult. Gladstone naturally turned rather to his old friends, Granville and Spencer, and had little personal sympathy with the new men. Dilke and Chamberlain stood for more far-reaching social reforms at home than their elder colleagues, and on foreign affairs there were many difficulties. In Egypt Chamberlain demanded more vigorous measures after the massacre at Alexandria (1882), yet insisted that the Government must not be tied to the bondholders' interest, but must give legitimate effect to Egyptian nationalist aspirations. Again in Feb. 1884 he would have given instructions to Baring to arrange for the relief of the Sudan garrisons, but no steps were taken, and, when at last a much more elaborate expedition than that at first urged by Chamberlain was sent, it was too late to avoid the tragedy of Gordon.

Irish Policy.—But the deepest fissure was on Irish policy. Chamberlain hated coercion, and held a positive view of Irish affairs. He made a personal effort in 1882 to heal the Irish sore. On the understanding that he would be disavowed if he failed, he was authorized to negotiate with Parnell and succeeded. The result was the "Kilmainham treaty." Parnell, on May 2, 1882, was released from Kilmainham gaol, having agreed to advise the cessation of outrages and the payment of rent, while Gladstone's ministry was to relax its coercive administration. Thereupon, W. E. Forster, the Irish secretary, resigned. His successor, the blameless Lord Frederick Cavendish, was immediately murdered in Phoenix park. This tragedy darkened the whole aspect of Irish affairs. Chamberlain, conspicuously marked out for the post of danger, was prepared to face the risk, but was not appointed. He refused to allow the tragedy to divert him from a definitely remedial policy. Eventually in 1885, after indirect negotiation through Capt. O'Shea with Parnell, he placed before the cabinet a scheme for Irish government on lines of semi-Home Rule without weakening, however, the imperial connection. A "central council," or national elective board was to be set up in Dublin, and Parnell was to forego obstruction to a bill which would reduce coercion to a minimum. The Irish bishops were thought to favour the plan. When these proposals for devolution came before the cabinet (May 9) all the peers, except Granville, voted against them; of the commoners only Hartington opposed them. Proposals for a Coercion bill and a land purchase bill were then put forward. Dilke and Chamberlain resigned, the latter being definitely opposed to land purchase unaccompanied by local autonomy. But the resignations did not take effect before the Government was defeated on the budget (June 8).

Both before and after the defeat Chamberlain associated himself with what was known as the "unauthorized programme," *i.e.*, free education, small holdings for agricultural labourers, graduated taxation and local government. In June 1885 he made a speech at Birmingham, treating the reforms just mentioned as the "ransom" that property must pay to society for the security it enjoys. In October Chamberlain defined his ideas to Gladstone. They were that local authorities must have the right of appropriation for public purposes, that a radical readjustment of taxation was necessary, and that ministers must be free to advocate free education, even if some of their colleagues opposed it. At the general election of Nov. 1885 Chamberlain was returned for West Birmingham. The Liberal strength in the nation generally was, however, reduced to 335 members, though the Radical section held their own; and the Irish vote became necessary to Gladstone if he was to command a majority. Chamberlain still had an open mind on the Irish question. He foresaw that between Home Rule and separation there was but a step, and in a letter written on Dec. 26 he went so far as to discuss a federalist scheme for the British Isles with five separate parliaments. In December it was stated that Gladstone intended to propose Home Rule for Ireland, and when the new parliament met in Jan. 1886 Lord Salisbury's ministry was defeated on the address, on an amendment moved by Chamberlain's Birmingham henchman, Jesse Collings, embodying the "three acres and a cow" of the Radical programme. Lord Hartington (afterwards duke of Devonshire) and some other Liberals, declined to join Gladstone in view of the altered attitude he was adopting towards Ireland. But Chamberlain—stipulating for liberty of judgment on the prime minister's Irish policy when embodied in definite legislative shape—entered the cabinet as president of the Local Government Board (with Jesse Collings as parliamentary secretary). On March 15, 1886, he resigned, explaining in the House of Commons (April 8), that while he had always been in favour of the largest extension of local government to Ireland consistent

with the integrity of the empire and the supremacy of the imperial parliament, and had therefore joined Gladstone when he believed that agreement might be possible, he was unable to recognize that the scheme communicated by Gladstone to his colleagues maintained those conditions. At the same time he was not irreconcilable, and invited Gladstone even then to modify the bill so as to remove the objections of Radical dissentients. This indecisive attitude did not last long, and the split in the party rapidly widened. At Birmingham Chamberlain was supported by the local "Two Thousand," but deserted by the national "Caucus" of the Liberal party and by its organizer, his own former lieutenant, Schnadhorst. In May the Radicals who followed Bright and Chamberlain, and the Whigs who took their cue from Lord Hartington, decided to vote against the second reading of the Home Rule bill, instead of allowing it to be taken and then pressing for modifications in committee, and on June 7 the bill was defeated by 343 to 313, 94 Liberal Unionists—as they were generally called—voting against the Government. Chamberlain was the object of the bitterest attacks from the Gladstonians for his share in this result; and open war was proclaimed by the Home Rulers against the "dissentient Liberals"—the description used by Gladstone. The general election, however, returned to Parliament 316 Conservatives, 78 Liberal Unionists, and only 276 Gladstonians and Nationalists, Birmingham returning seven Unionist members. When the House met in August, it was decided by the Liberal Unionists, under Hartington's leadership, that their policy henceforth was essentially to put in the Tories and to keep Gladstone out. The old Libe ing still prevailing among them was too strong, however, for their leaders to take office in a coalition ministry. For them as a whole it was enough to be able to tie down the Conservative Government to such measures as were not offensive to Liberal Unionist principles; but Chamberlain from the first was determined to impose on that Government a progressive policy in British social questions as the price of his indispensable support on the Irish question. It still seemed possible, moreover, that the Gladstonians might be brought to modify their Home Rule proposals, and in Jan. 1887 a Round Table conference, suggested by Chamberlain, was held between him and Sir G. Trevelyan for the Liberal Unionists, with Sir William Harcourt, John Morley and Lord Herschell for the Gladstonians, but no *rapprochement* was effected.

Reform.—The influence of his views upon the domestic legislation of the Government was bringing about a more complete union in the Unionist party, and destroying the old lines of political cleavage. Before 1892 Chamberlain had the satisfaction of seeing Lord Salisbury's ministry pass such important acts, from a progressive standpoint, as those dealing with coal mines regulation, allotments, county councils, housing of the working classes, free education and agricultural holdings, besides Irish legislation like the Ashbourne Act, the Land Act of 1891, and the Light Railways and Congested District acts.

In Oct. 1887, Chamberlain, Sir L. Sackville West and Sir Charles Tupper were selected by the Government as British plenipotentiaries to discuss with the United States the Canadian fisheries dispute, and a treaty was signed by them at Washington on February 15, 1888. The Senate, however, refused to ratify it; but a protocol provided for a *modus vivendi* giving American fishing vessels similar advantages to those contemplated in the treaty. This arrangement, prolonged from year to year, proved to be a real settlement. Chamberlain returned home in March, his already strong feelings of friendliness to the United States much strengthened. This sentiment was reinforced in Nov. 1888, by his marriage with his third wife, Miss Endicott, daughter of the United States secretary of war in President Cleveland's first administration.

At the general election of 1892 Chamberlain was again returned, with an increased majority, for West Birmingham, but the Unionist party as a whole was narrowly defeated; the Irish Nationalist vote again held the balance in the House of Commons and, with a small and precarious majority, Gladstone returned to office, pledged to Home Rule for Ireland. On Feb. 13, 1893, that wonderful veteran, now in his 84th year, introduced his second Home Rule bill, which was read a third time on Sept. 1. During the 82 days' discussion in the House of Commons Chamberlain was its most acute, ceaseless, unsparing critic, and he moved public opinion outside the House. His chief contribution to the discussions during the later stages of the Gladstone and Rosebery ministries was in connection with Asquith's abortive Employers' Liability bill, when he foreshadowed the broader method of "compensation for accidents," afterwards carried out, in favour of the working classes by the act of 1897. Outside parliament he was busy formulating proposals for old age pensions, which had a prominent place in the Unionist programme of 1895. After his visit to America in 1889 he was developing the imperialist outlook which profoundly modified his future activity.

South Africa.—In 1895 he became secretary of State for the colonies in Lord Salisbury's ministry. His influence in the Unionist cabinet was soon visible in the Workmen's Compensation act and other measures. This act, though in formal charge of the home secretary, was universally and rightly associated with Chamberlain. Another less important "social" measure, which formed part of the Chamberlain programme, was the Small Houses Acquisition Act of 1899; but the problem of old age pensions was less easily solved. This subject had been handed over in 1893 to a royal commission, and further discussed by a select committee in 1899 and a departmental committee in 1900, but both of these threw cold water on the schemes laid before them.

From New Year 1896 (the date of the Jameson Raid) onwards South Africa demanded the chief attention of the colonial secretary (*see* SOUTH AFRICA, and for details TRANSVAAL). In his negotiations with President Kruger one masterful temperament was pitted against another. Chamberlain had a very difficult part to play in a situation dominated by suspicion on both sides. While he firmly insisted on the rights of Great Britain and of British subjects in the Transvaal, he was the continual object of Radical criticism at home. Attempts were even made to ascribe financial motives to Chamberlain's actions, and the political atmosphere was thick with suspicion and scandal. The report of the Commons committee (July 1897) definitely acquitted both Chamberlain and the Colonial Office of any privity in the Jameson Raid, but Chamberlain's detractors continued to assert the contrary. Opposition hostility reached such a pitch that in 1899 there was hardly an act of the cabinet during the negotiations with President Kruger which was not attributed to the personal malignity and unscrupulousness of the colonial secretary. In fact he gave ample scope to the man on the spot, Sir Alfred (Lord) Milner, whom he had sent out as high commissioner in 1897. The Bloemfontein Conference of 1899 was a serious attempt to secure amicable agreement; but its failure did not deter Chamberlain from making repeated efforts to ensure peace. In the Transvaal the original Boer burghers had become an armed minority, determined at all costs to maintain its racial ascendancy. Since the opening of the gold mines, the unenfranchised outlanders, chiefly British, had become the majority of the adult inhabitants and supplied most of the revenue. Their plight was one of "taxation without representation." Chamberlain offered as part of a general settlement of the franchise and other outstanding questions, to give complete guarantees against any attack on the independence of the republic. But President Kruger's ultimatum demanded, in effect, the military withdrawal and political abdication of Britain in South Africa, and the Boer War began. It lasted for over 2½ years before the two Dutch republics formally surrendered. Throughout this period, Chamberlain was the mainstay of British public opinion when nearly all the world was hostile. The elections of 1900 (when he was again returned, unopposed, for West Birmingham) turned upon the individuality of a single minister more than any since the days of Gladstone's ascendancy, and Chamberlain, never conspicuous for inclination to turn his other cheek to the smiter, was not slow to return the blows with interest.

Apart from South Africa, his most important work at this time was the successful passing of the Australian Commonwealth Act (1900), when both tact and firmness were needed to settle certain differences between the imperial Government and the colonial

delegates.

Chamberlain's tenure of the office of colonial secretary between 1895 and 1900 must always be regarded as a turning-point in the history of the relations between the British colonies and the mother country. In spirit he was an imperial federationist even before his separation from Gladstone. From 1887 onwards he worked for a *rapprochement* of the different parts of the empire for purposes of defence and commerce. In 1895 he struck a new note of constructive statesmanship, basing itself on the economic necessities of a world-wide empire. Not the least of the anxieties of the Colonial Office during this period was the situation in the West Indies, where the cane-sugar industry was being steadily undermined by the European bounties given to exports of Continental beet, and though the Government restricted themselves to attempts at removing the bounties by negotiation and to measures for palliating the worst effects in the West Indies, Chamberlain made no secret of his repudiation of the Cobden club view that retaliation would be contrary to the doctrines of free trade. He set to work to educate public opinion at home into understanding that the responsibilities of the mother country are not merely to be construed according to the selfish interests of a nation of consumers. As regards foreign affairs, Chamberlain more than once (particularly at Birmingham, May 13 1898, and at Leicester, Nov. 30, 1899) indicated his leanings towards a closer understanding between the British empire, the United States and Germany. The unusually outspoken and pointed expression, however, of his disinclination to submit to Muscovite duplicity or to "pin-pricks" or "unmannerliness" from France was widely criticized. For three years from the spring of 1898 to 1901 he worked strenuously in secret for an Anglo-German alliance. He was convinced that this project was the chief key to the peace of the world. The Kaiser and Bülow hoped rather by keeping free hands to become arbiters of the world.

Boer War.—During the progress of the Boer War from 1899 to 1902 Chamberlain, as colonial secretary, naturally played only a subordinate part during the carrying out of the military operations But in parliament and on the platform he was more than ever supreme—the chief animating influence of the British empire. He was the hero of the one side, just as he was the bugbear of the other On Feb. 13, 1902, he was presented with an address in a gold casket by the corporation of the city of London, and entertained at luncheon at the Mansion House, an honour not unconnected with the strong feeling recently aroused by his firm reply (at Birmingham, Jan. 11) to disparaging remarks made by the German chancellor in the Reichstag (Jan. 8). Against offensive allegations abroad Chamberlain had defended the British army in South Africa, and declared its conduct to be as good as that of the Germans in 1870–71. The way in which England's difficulties called forth colonial assistance intensified his imperialism. More and more the problems of empire engrossed him, and a new enthusiasm for imperial projects arose in the Unionist party under his inspiration. No English statesman probably—except Peel—has ever been, at different times in his career, so able an advocate of apparently contradictory policies, and his opponents baited him with quotations from his earlier speeches. He replied in effect that to flinch from adopting new methods and even new opinions in face of totally changed circumstances, is either practical folly or moral cowardice.

The settlement after the war was full of difficulties, financial and others, in South Africa. When Arthur Balfour succeeded Lord Salisbury as prime minister in July 1902, Chamberlain agreed to serve loyally under him, and the friendship between the two leaders was indeed one of the most marked features of the political situation. In Nov. 1902 Chamberlain, bent upon a conciliatory settlement with the Boers, went out to South Africa. He travelled from place to place (Dec. 26–Feb. 25), arranged with the leading Transvaal financiers that in return for support from the British Government in raising a Transvaal loan they would guarantee a large proportion of a Transvaal debt of £30,000,000 which, by so much, should repay the British Treasury the cost of the war, and when he returned in March 1903, satisfaction was general in the country over the success of his mission. But meantime two things had happened. He desired above all things imperial union. At the Imperial Conference of 1902 the attitude of the overseas premiers had shown that the only way to the beginnings of a closer political union of the whole empire was on lines of mutually preferential commerce, deviating from the strict traditional doctrines of "free trade"—that is of equally free imports for all products, whether of foreign or British—imperial origin. But at home—while he was still in South Africa—some of his colleagues had gone a long way, behind the scenes, to destroy one of the very factors on which the practical scheme for imperial commercial federation seemed to hinge. In the budget of 1902 a duty of a shilling a quarter on imported corn had been reintroduced. This small tax was regarded as only a registration duty. Even by free-trade ministers like Gladstone it had been left up to 1869 untouched, and its removal by Robert Lowe (Lord Sherbrooke) had since then been widely regarded as a piece of economic pedantry. The more advanced imperialists, as well as the more old-fashioned protectionists (like Lord Chaplin) who formed a small but integral part of the Conservative body, had looked forward to this tax being converted into a differential one between foreign and colonial corn, so as to introduce a scheme of colonial preference. The latter principle would be introduced even by a remission of sixpence in favour of grain grown "under the flag" overseas. Ritchie, the chancellor of the exchequer, having a surplus in prospect and taxation to take off, persuaded the cabinet to abolish the corn-duty altogether. Chamberlain himself had proposed only to take it off as regards colonial, but not foreign corn—thus inaugurating a preferential system—and when he left for South Africa he did not imagine that this principle was in danger. But in his absence, a majority of the cabinet supported Ritchie. To those who had hoped so to handle the tax as to make it a lever for a gradual change in the established fiscal system, the total abolition was a bitter blow. At once there began, though not at first openly, a split between the more rigid free-traders—advocates of cheap food and free imports—and those who desired to use the opportunities of a tariff, of however moderate a kind, for attaining national and imperial and not merely revenue advantages. This idea had for some time been forming in Chamberlain's mind, and now took full possession of it. For the moment he remained in the cabinet, but the seed of dissension was sown. The first public intimation of his views was given in an epoch-marking speech to his constituents at Birmingham (May 15, 1903), when he outlined a plan for raising more money by a rearranged tariff, partly to obtain a preferential system for the empire and partly to produce funds for social reform at home. On May 28 in the House of Commons he spoke on the same subject, and declared "if you are to give a preference to the colonies, you must put a tax on food." Putting the necessity of food-taxes in the forefront was injudicious; but imperialist conviction and enthusiasm were more conspicuous than electioneering prudence in the launching of Chamberlain's new scheme. His courage was heroic; his tactics fell short of the old unfailing mastery of manoeuvre.

Tariff Reform.—Chamberlain argued that since 1870 certain other countries (Germany and the United States), with protective tariffs, had increased their trade in much larger proportion, while English trade had been chiefly maintained by the increased business done with British colonies. A scientific enquiry into the facts was needed. For a time the demand merely for enquiry, and the production of figures, gave no sufficient occasion for dissension among Unionists, even when, like Sir M. Hicks Beach, they were convinced free-importers on purely economic as well as political grounds. Balfour, as premier, managed to hold his colleagues and party together by taking the line that particular opinions on economic subjects should not be made a test of party loyalty. The Tariff Reform League was founded in order to further Chamberlain's policy, holding its inaugural meeting on July 21; and it began to take an active part in issuing leaflets and in work at by-elections.

Meanwhile, the death of Lord Salisbury (Aug. 22) removed a weighty figure from the councils of the Unionist party. The cabinet met several times at the beginning of September, and the

question of their attitude towards the fiscal problem became acute. The public had its first intimation of impending events in the appearance on Sept. 16 of Balfour's *Economic Notes on Insular Free Trade*, which had been previously circulated as a cabinet memorandum. The next day appeared the Board of Trade Fiscal Blue-Book, and on the 18th conflicting resignations were announced—not only of the more rigid free-traders in the cabinet, Ritchie and Lord George Hamilton, but also of Chamberlain himself for the opposite reason. His exit from the British Government after eight years of office was an event discussed with interest throughout the world.

Letters in cordial terms were published, which had passed between Chamberlain (Sept. 9) and Balfour (Sept. 16). Chamberlain pointed out that he was committed to a preferential scheme involving new duties on food, and could not remain in the Government without prejudice while it was excluded from the party programme; remaining loyal to Balfour and his general objects, he could best promote this course from outside, and he suggested that the Government might confine its policy to the "assertion of our freedom in the caste of all commercial relations with foreign countries." Balfour, while reluctantly admitting the necessity of Chamberlain's taking a freer hand, expressed his agreement in the desirability of a closer fiscal union with the colonies, but questioned the immediate practicability of any scheme; he was willing to adopt fiscal reform so far as it covered retaliatory duties, but thought that the exclusion of taxation of food from the party programme was in existing circumstances necessary, so long as public opinion was not ripe.

The tariff reform movement itself was now outside the purely official programme, and Chamberlain (backed by a majority of the Unionist members) threw himself with impetuous ardour into a crusade on its behalf, while at the same time supporting Balfour in parliament, and leaving it to him to decide as to the policy of going to the country when the time should be ripe. On Oct. 6 he opened his campaign with a speech at Glasgow. Analysing the trade statistics as between 1872 and 1902, he insisted that British progress involved a relative decline compared with that of protectionist foreign countries like Germany and the United States; Great Britain exported less and less of manufactured goods, and imported more and more; the exports to foreign countries had decreased, and it was only the increased exports to the colonies that maintained the British position. This was the outcome of the working of a one-sided free-trade system. Now was the time for consolidating British trade relations with the colonies. A further increase of £26,000,000 a year in the trade with the colonies might be obtained by a preferential tariff, and this meant additional employment at home for 166,000 workmen, or subsistence for a population of a far larger number. His positive proposals were: (1) no tax on raw materials; (2) a small tax on food other than colonial, *e.g.*, two shillings a quarter on foreign corn but excepting maize, and 5% on meat and dairy produce excluding bacon; (3) a 10% general tariff on imported manufactured goods. To meet any increased cost of living, he proposed to reduce the duties on tea, sugar and other articles of general consumption.

Colonial Preference.—"The colonies," he said, "are prepared to meet us; in return for a very moderate preference, they will give us a substantial advantage in their markets." This speech was the type of others which followed quickly during the year. At Greenock next day he emphasized the necessity of retaliating against foreign tariffs. The practice of "dumping" must be met; if foreign goods were brought into England to undersell British manufacturers, either the Fair Wages clause and the Factory Acts and the Compensation Act would have to be repealed, or the workmen would have to take lower wages, or lose their work, "Agriculture has been practically destroyed, sugar has gone, silk has gone, iron is threatened, wool is threatened, cotton will go! How long are you going to stand it?" In all his speeches he managed to point his argument by application to local industries. On Jan. 18, 1904, Chamberlain ended his series of speeches by a meeting at the Guildhall, in the city of London, the key-note being his exhortation to his audience to "think imperially."

Chamberlain needed a rest, and was away in Italy and Egypt from March to May, 1904, and again in November. He made three important speeches at Welbeck (Aug. 4), at Luton (Oct. 5), and at Limehouse (Dec. 15), but he had nothing substantial to add to his case. The Russo-Japanese War in Manchuria distracted popular attention from his campaign.

In Jan. 1905 some correspondence was published between Chamberlain and the duke of Devonshire, dating from the previous October, as to difficulties arising from the central Liberal-Unionist organization subsidizing local associations which had adopted the programme of tariff reform. The duke objected to this departure from neutrality, and suggested that it was becoming "impossible with any advantage to maintain under existing circumstances the existence of the Liberal-Unionist organization." Chamberlain retorted that this was a matter for a general meeting of delegates to decide; if the duke was out-voted he might resign his presidency; for his own part he was prepared to allow the local associations to be subsidized impartially, so long as they supported the Government, but he was not prepared for the violent disruption, which the duke apparently contemplated, of an association so necessary to the success of the Unionist cause. The duke was in a difficult position as president of the organization, since most of the local associations supported Chamberlain; and he replied that the differences between them were vital, and he would not be responsible for dividing the association into sections, but would rather resign. Chamberlain then called a general meeting on his own responsibility in February, when a new constitution was proposed; and in May, at the annual meeting of the Liberal-Unionist council, the free-food Unionists, being in a minority, retired, and the association was reorganized under Chamberlain's auspices, Lord Lansdowne and Lord Selborne (both of them cabinet ministers) becoming vice-presidents. On July 14 the reconstituted Liberal-Unionist organization held a great demonstration in the Albert hall, and Chamberlain's success in ousting the duke of Devonshire and the other free-trade members of the old Liberal-Unionist party, and imposing his own fiscal policy upon the Liberal-Unionist caucus, was now complete.

In reply to Balfour's appeal for the sinking of differences (Newcastle, Nov. 14), Chamberlain insisted at Bristol (Nov. 21) on the adoption of his fiscal policy; and Balfour resigned on Dec. 4 on the ground that he no longer retained the confidence of the party. At the crushing Unionist defeat in the general election which followed in Jan. 1906, Chamberlain was triumphantly returned for West Birmingham, and all the divisions of Birmingham returned Chamberlainite members. This, by contrast with the national disaster to the Unionist party as a whole, was one of the astonishing features of all British electoral history.

But he had no desire to set himself up as leader in Balfour's place, and after private negotiations with the ex-prime minister, a common platform was arranged between them, on which Balfour—for whom a seat was found in the City of London—should continue to lead the remnant of the party. The "Valentine's Day" formula was given in a letter from Balfour of Feb. 14 which admitted the necessity of making fiscal reform the first plank in the Unionist platform, and accepted a general tariff on manufactured goods and a small duty on foreign corn as "not in principle objectionable."

It may be left to future historians to attempt a considered judgment on the English tariff reform movement, and on Chamberlain's responsibility for the Unionist *débâcle* of 1906. But while his enemies taunted him with having twice wrecked his party—first the Radical party under Gladstone, and secondly the Unionist party under Balfour—no well-informed critic doubted his sincerity, or failed to recognize that in leaving the cabinet and embarking on his fiscal campaign he showed real devotion to an idea. In championing the cause of imperial fiscal union, by means involving the abandonment of a system of taxation which had become part of British orthodoxy, he followed the guidance of a profound conviction that the stability of the empire and the very existence of the hegemony of the United Kingdom depended upon the conversion of public opinion to a revision of the current economic doctrine. For the second time he had staked an already

established position on his refusal to compromise with his convictions on a question which appeared to him of vital and immediate importance.

Mr. Chamberlain's own activity in the political field was cut short in the middle of the session of 1906. His 70th birthday was celebrated in Birmingham with immense enthusiasm shared in spirit by the bulk of the Unionist party in Great Britain and by idealists of imperialism throughout the British dominions. His fatigue before this apotheosis was extreme. Immediately afterwards he had a stroke of paralysis. He never spoke in public again. Though, for some time, his adherents hoped that he might return to the House of Commons, he was quite incapacitated for any public work. At the general election of Jan. 1910 Chamberlain was returned unopposed for West Birmingham again. His last sad appearance in the House was in the February following when, while few members were present, the formality of signing the roll was performed for him by his eldest son.

He died at his house, Highbury, Birmingham, on July 2, 1914. His last speech had been made on July 9, 1906. In that speech he uttered words which may fairly be given as his political testament: "The union of the Empire," he said, "must be preceded and accompanied by a better understanding, by a better sympathy. To secure that is the highest object of statesmanship now at the beginning of the 20th century; and if these were the last words that I were permitted to utter to you, I would rejoice to utter them in your presence, and with your approval. I know that the fruition of our hopes is certain. I hope I may live to congratulate you upon our common triumph; but in any case I have faith in the people. I trust in the good sense, the intelligence and the patriotism of the majority, the vast majority, of my countrymen."

Joseph Chamberlain had a singularly happy home life, and during his long illness had the devoted attention of Mrs. Chamberlain. Both his sons, Joseph Austen and Arthur Neville, rose to high position amongst statesmen, and are separately noticed.

See H. W. Lucy, *Speeches of Joseph Chamberlain, with a sketch of his life* (1885); *Speeches on Home Rule and the Irish Question 1885–87* (1887); *Foreign and Colonial Speeches* (1897); *Imperial Union and Tariff Reform, 15 May–Nov. 4, 1903* (2nd ed. 1910); C. W. Boyd, *Mr. Chamberlain's Speeches* (2 vols., 1914). The authorized *Life* of Chamberlain, by J. L. Garvin, is in preparation. The existing biographies were written during Chamberlain's lifetime by N. M. Marris (1900), S. H. Jeyes (1903), Louis Creswick (4 vols., 1904), Alexander Mackintosh (1906) and by Viscount Milner, J. Spender, Sir Henry Lucy and others (pub. 1912). Much information, including letters and reports of conversations, is to be found in biographies of his contemporaries, notably in those of Gladstone, the duke of Devonshire, Granville, Goschen and Harcourt, which will be found noted under those heads. For the South African period see the despatches published in the parliamentary papers series, Accounts and Papers (Colonies and British Possessions, South Africa), for the years in question, and *The "Times" History of the War in South Africa* (edit. L. C. S. Amery, vol. i. and vi. 1900–09); and for the suggested *rapprochement* with Germany at the turn of the century, F. Fischer, *Holstein's grosses Nein; Die deutschenglischen Bündnisverhandlungen von, 1898–1901* (1925); H. von Eckhardstein, *Lebens erinnerungen und politische Denkwürdigkeiten* (Leipzig, 1919, etc.); Erich Brandenburg, *Von Bismarck zum Weltkriege* (1924, trans. by A. E. Adams, 1927); *Die Grossepolitik der Europäischen Kabinette, 1871–1914;* and F. Meinecke, *Geschichte des Deutsch Englischen Bundnissproblems, 1890–1901* (1927).

CHAMBERLAIN, SIR NEVILLE BOWLES (1820–1902), British field-marshal, was born at Rio de Janeiro Jan. 10, 1820, the son of Henry Chamberlain, consul-general and chargé d'affaires in Brazil. He entered the East India Company's army in 1837 and served in the first Afghan war (1839–42), in the Gwalior campaign of 1843, and in the Punjab campaign of 1848–49. After that date, promotion was rapid, and he commanded several expeditions against the tribes on the northwest frontier. During the Indian mutiny he became adjutant general of the Indian army and, for his services at the siege of Delhi and elsewhere, was rewarded with a series of honours. He gained more honours after the Umbeyla campaign in 1863. Chamberlain was made lieutenant general in 1872 and appointed G.C.S.I. in 1873 and G.C.B. in 1875. From 1876 to 1881 he was commander in chief of the Madras army. In 1879 he was sent on a mission to Sher Ali, whose refusal to allow him to enter Afghanistan precipitated the outbreak of the second Afghan war. Chamberlain agreed with Lord Lytton that the British government should take steps to show its resentment at a "gross and unprovoked insult," but he did not approve of the policy of disintegration of Afghanistan adopted by Lytton after the second occupation of Kabul. He disapproved of the retention of Kandahar in 1880, recognizing the difficulty involved in maintaining additional outposts. He returned to England in 1881 and received the rank of field marshal in 1900. He died at Lordswood, near Southampton, Feb. 18, 1902.

See W. H. Page and A. H. Mason, *Record of the Expeditions against the North-West Frontier Tribes* (London, 1884); G. W. Forrest, *Life of Chamberlain* (1909).

CHAMBERLAIN, etymologically, and also to a large extent historically, an officer charged with the superintendence of domestic affairs. Such were the chamberlains of monasteries or cathedrals, who had charge of the finances, gave notice of chapter meetings, and provided the materials necessary for the services. In these cases, as in that of the apostolic chamberlain of the Roman see, the title was borrowed from the usage of the courts of the western secular princes. A royal chamberlain is now a court official whose function is in general to attend on the person of the sovereign and to regulate the etiquette of the palace. He is the representative of the mediaeval *camberlanus, cambellanus* or *cubicularius,* whose office was modelled on that of the *praefectus sacri cubiculi* or *cubicularius* of the Roman emperors. But at the outset there was another class of chamberlains, the *camerarii, i.e.,* high officials charged with the administration of the royal treasury (*camera*). The *camerarius* of the Carolingian emperors was the equivalent of the *hordere* or *thesaurarius* (treasurer) of the Anglo-Saxon kings; he develops into the *Erzkämmerer* (*archicamerarius*) of the Holy Roman Empire, an office held by the margraves of Brandenburg, and the *grand chambrier* of France, who held his *chamberie* as a fief. Similarly in England after the Norman conquest the *hordere* becomes the chamberlain. This office was of great importance. Before the Conquest the *hordere* had been, with the marshal, the principal officer of the king's court; and under the Norman sovereigns his functions were manifold. As he had charge of the administration of the royal household, his office was of financial importance, for a portion of the royal revenue was paid, not into the exchequer, but in *camera regis.* In time the office became hereditary and titular, but the complexity of the duties necessitated a division of the work, and the office was split up into three: the hereditary and sinecure office of *magister camerarius* or lord great chamberlain (*q.v.*) the more important domestic office of *camerarius regis,* king's chamberlain or lord chamberlain (*q.v.*) and the chamberlains (*camerarii*) of the exchequer, two in number, who were originally representatives of the chamberlain at the exchequer, and afterwards in conjunction with the treasurer presided over that department. In 1826 the last of these officials died, when by an act passed 44 years earlier they disappeared.

In France the office of *grand chambrier* was early overshadowed by the *chamberlains* (*cubicularii, cambellani,* but sometimes also *camerarii*), officials in close personal attendance on the king, men at first of low rank, but of great and ever-increasing influence. As the office of *grand chambrier,* held by great feudal nobles seldom at court, became more and more honorary, the chamberlains grew in power, in numbers, and in rank, until, in the 13th century, one of them emerges as a great officer of State, the *chambellan de France* or *grand chambellan* (also *magister cambellanorum, mestre chamberlenc*), who at times shares with the *grand chambrier* the revenues derived from certain trades in the city of Paris. The honorary office of *grand chambrier* survived till the time of Henry II., who was himself the last to hold it before his accession; that of *grand chambellan,* which in its turn soon became purely honorary, survived till the Revolution. Among the prerogatives of the *grand chambellan,* which survived to the last, was the right to hand the king his shirt at the ceremonial levee. The offices of *grand chambellan, premier chambellan,* and *chambellan* were revived by Napoleon, continued under the Restoration, abolished by Louis Philippe, and again restored by Napoleon III.

In the papal Curia the apostolic chamberlain (*camerarius*) is at the head of the treasury (*camera thesauraria*) and, in the days of the temporal power, not only administered the papal finances but possessed an extensive civil and criminal jurisdiction. During a vacancy of the Holy See he is at the head of the administration of the Roman Church. The office dates from the 11th century, when it superseded that of archdeacon of the Roman Church, and the close personal relations of the *camerarius* with the pope, together with the fact that he is the official guardian of the ceremonial vestments and treasures, point to the fact that he is also the representative of the former *vestararius* and *vice-dominus*, whose functions were merged in the new office.

In England the modern representatives of the *cubicularii* are the gentlemen and grooms of the bed-chamber; in Germany were the *Kammerherr* (*Kämmerer*, from *camerarius*, in Bavaria and Austria) and *Kammerjunker*. The insignia of their office is a gold key attached to their coats behind.

Many corporations appoint a chamberlain. The chamberlain of the corporation of the city of London, who is treasurer of the corporation, admits persons to the freedom of the city, and, in the chamberlain's court, of which he and the vice-chamberlain are judges, exercises concurrent jurisdiction with the police court in determining disputes between masters and apprentices. Formerly nominated by the crown, since 1688 he has been elected annually by the liverymen. He has a salary of £2,000 a year. Similarly in Germany the administration of the finances of a city is called the *Kämmerei* and the official in charge of it the *Kämmerer*.

"Camerarius" and "Cambellanus"; Père Anselme, *Hist. généalogique et chronologique de la maison royale de France, etc.* (3rd ed. 1726–33); A. Luchaire, *Manuel des institutions françaises* (1892); W. R. Anson, *Law and Custom of the Constitution* (1896); Hinschius, *Kirchenrecht*, i. 405 (1869).

CHAMBERLAYNE, WILLIAM (1619–1679), English poet, died on July 11, 1679. Nothing is known of his history except that he practised as a physician at Shaftesbury in Dorsetshire, and fought on the Royalist side at the second battle of Newbury. His works are: *Pharonnida* (1659), a verse romance in five books; *Love's Victory* (1658), a tragi-comedy, acted under another title in 1678 at the Theatre Royal; *England's Jubilee* (1660), a poem in honour of the Restoration. A prose version of *Pharonnida*, entitled *Eromena* or *The Noble Stranger*, appeared in 1683. Southey speaks of him as "a poet to whom I am indebted for many hours of delight." *Pharonnida* was reprinted by S. W. Singer in 1820, and again in 1905 by Prof. G. Saintsbury in *Minor Poets of the Caroline Period* (vol. i.). The poem is loose in construction, but contains some passages of great beauty.

CHAMBERLIN, THOMAS CHROWDER (1843–1928), American educator and geologist, was born at Mattoon, Ill., on Sept. 25, 1843. He graduated at Beloit college in 1866 (A.B.) and returned to the college in 1873 as professor of geology, serving also as assistant State geologist of Wisconsin until 1876, when he was made chief geologist of the Wisconsin Geological Survey (1876–82). From 1882 to 1887 he served as U.S. geologist in charge of the glacial division; from 1887 to 1892, as president of the University of Wisconsin; from 1892 to 1919, as head of the geological department of the University of Chicago, retiring as professor emeritus in 1919. He studied glaciers in Switzerland in 1878 and in Greenland in 1894, as geologist to the Peary relief expedition. His principal scientific work in later years has been the study of fundamental problems in geology particularly as related to the origin and growth of the earth, the developing of the planetesimal hypothesis of the planets, planetoids and satellites; and the chondrulitic hypothesis of the origin of chondrulites, comets and meteorites. He died in Chicago, Nov. 15, 1928.

His chief publications are *Geology of Wisconsin* (1879–82); *Reports of the Glacial division U.S. Geol. Survey* (1882–87); a three-volume treatise on geology (with R. D. Salisbury, 1906); reports on researches on certain fundamental problems in geology to the Carnegie Institution of Washington, *Year Books* 2 to 27; *The Tidal and Other Problems* (1909), "Diastrophism and the Formative Processes," numerous articles in the *Journal of Geology*, vol. xxi. (1913–21); *The Origin of the Earth* (1916); *The Two Solar Families, The Sun's Children* (1928).

CHAMBER MUSIC, a term obviously denoting music for performance in a room of a private house, has acquired the special meaning of large works in the sonata style for a group of individual instruments; although it may be borne in mind that in the early 18th century vocal cantatas for solo voices were at least as important as purely instrumental compositions.

One feature of immaturity is common to all the chamber music, vocal and instrumental, between and including Corelli and Bach; namely, that the harmonic background is left to the harpsichord player to extemporize from the indications given by a figured bass (*q.v.*). Even works with elaborate obligato harpsichord parts, have passages which presuppose this extempore element. Only the concerted music of the French clavecinists Couperin and Rameau consistently leaves nothing undetermined.

Works with Continuo.—The forms of chamber music are those of music at large, and it has no independent history. But it is very definite in the principles which determine its texture; and the element of the figured bass or continuo puts the earlier chamber music into an altogether different category from the art which arose with Haydn. As is shown in the articles INSTRUMENTATION, MUSIC and SONATA FORMS, the sonata-style of Haydn and Mozart irrevocably brought the dramatic element into music; but in addition to this, it brought alike into chamber music and orchestral music a fundamental principle that all players in an instrumental combination should between them provide their own harmonic background without the aid of a continuo part.

The disappearance of the continuo in later chamber music marks the realization of the central classical idea of the style, according to which there is no part in the ensemble left either indeterminate or in permanent subordination.

With its disappearance must also disappear the conception of the ensemble as a group of treble instruments over a firm bass, requiring a middle mass of harmony on an altogether remoter plane to hold them together. The middle part must be on the same plane as the others, and all must be as ready to provide the background as to carry on the main lines. There were no string quartets in the continuo period; and, what is more significant, the viola parts in the orchestra of Bach and Handel are, except when accompanying a choral fugue, neither interesting in themselves nor sufficient to fill up the gap between violins and bass. Their function is to reinforce the continuo without going a step out of their way to make the harmony always complete.

Haydn's first Quartets.—Rightly understood and performed, the result is perfectly mature; but it is worlds away from the crudest of Haydn's first quartets which, written before the death of Handel, show the criterion of self-sufficiency firmly established, so that there is no room for a continuo. The first string quartets are not clearly distinguished from orchestral music; wind parts have been discovered for Haydn's op. 1, No. 5 and op. 2, No. 3, and Haydn throughout his life remained capable of occasionally forgetting that his quartet-violoncello was not supported by a double-bass. But few processes in the history of music are more fascinating than the steady emergence of Haydn's quartet-style from the matrix of orchestral habit. In the quartets of op. 9 which he afterwards wished to regard as the beginning of his work, the four string parts are equally necessary and equally alive. They are not equally prominent; because the criterion is not polyphony but self-sufficiency for the purposes of this kind of music; and in this kind of music the normal place for melody is on the top.

In the very important six quartets, op. 20, Haydn discovers the character of the violoncello as something more than a bass to the violins—you can hear him discover it in the fourth bar of op. 20, No. 1; and with this discovery all possibility of the use of a double-bass vanishes, though miscalculations occur in the latest quartets. Had Haydn been a great violoncellist his first quartets might have been as luxurious as the quintets of Boccherini (*q.v.*), and he might have dallied longer in the bypaths of a style which tries to give each instrument in turn its display

of solo-work. But Haydn's line of progress is steady and direct, and no document in the history of music is more important than his op. 20, with its three fugues (which secure autonomy and equality of parts by a return to the old polyphony), its passages of turn-about solo, its experiments in rich and special effects, and, most important of all, its achievements in quite normal quartet-writing such as pervades the remaining forty-odd quartets which end with his pathetic last fragment, op. 103.

Haydn's pianoforte trios also cover his whole career but they show, from first to last, no effort to achieve more than pianoforte sonatas with string accompaniment.

Mozart.—Mozart was an inveterate polyphonist by the time he was 12 years old, and the character of the viola, unnoticed by Haydn in his ripest quartets, is imaginatively realized in quartets written by Mozart at the age of 17. The point is not that the viola takes part in a more polyphonic style (though Mozart's early quartets are full of contrapuntal and canonic forms) but that the composer's imagination is attentive to the tone of the instrument in every note he writes for it.

Mozart's pianoforte trios, which are very insufficiently appreciated by historians and players, are perfect examples of independence of parts, no less than the two great pianoforte quartets (which should have been six but that the publisher cried off his bargain because of their difficulty) and the quintet for pianoforte and wind instruments. The set of six great string quartets (avowedly inspired by and affectionately dedicated to Haydn) contains some of the profoundest music outside Beethoven; and of the four remaining quartets, the last three, written for the King of Prussia, who was a good violoncellist, gave his majesty a grateful and prominent part and showed that Mozart's wit was able to maintain the full greatness of his style even when he was restricted to a lighter vein of sentiment.

His string quintets are as great as the quartets. Mozart prefers a second viola as the fifth member; and the only case where he suggested a second violoncello was by way of substitute for the horn in a little quintet for the curious combination of one violin, two violas, violoncello and horn. The combination of wind instruments with strings is a special problem the mention of which brings us back to reconsider the central idea of chamber music as now realized by Haydn and Mozart.

Vocal music has here dropped below the horizon. The human voice inevitably thrusts all instruments into the background; and we are now at the stage where the forces engaged in chamber music must be on planes sufficiently near to combine in one mental focus. A slight divergence of plane will give the mind pleasures analogous to those of stereoscopic vision. For example, the greatest masters of chamber music with pianoforte take pleasure in supporting heavy but incomplete pianoforte chords by the low notes of the violoncello: a procedure puzzling to self-centred pianoforte virtuosos, and never risked by composers who have not attained a pure style. Again, the clarinet, in the wonderful quintets by Mozart (A major) and Brahms (B minor) does not and is not intended to blend with the strings, but it nowhere gives a more intense pleasure than where it behaves as an inner part exactly like the others. These works belong to the highest regions of the art.

Wind and Other Combinations.—The flute blends with nothing; even among other wind instruments it is like water-colour among oils. It accordingly plays a part in witty little works, such as Beethoven's serenade for flute, violin and viola (twice imitated by Reger), and Mozart's two quartets with strings. The oboe, once not much less important in continuo chamber music than the flute (Handel confessed to "writing like a devil for it" when he was a boy) requires other wind instruments to relieve the ear of its plaintive tone, though Mozart wrote a pretty little quartet for it with strings, and Beethoven achieved a remarkable *tour-de-force* in an early trio for two oboes and cor anglais. But the further consideration of wind instruments brings us again to the borderland regions of chamber music. What are the smallest forces that can make a coherent combination for chamber music; and at what point do the forces become too large to cohere?

The pianoforte, even when treated in Mozart's hard-pencil line-drawing style, provides a central mass of complete harmony that can absorb shocks and combine (*pace* the virtuoso player) with anything. The question begins to be interesting when we deal with the strings alone. Duets for two violins are obviously a *tour-de-force*, since their bass can never go below a contralto G. This *tour-de-force* is executed on a large scale with a mastery and euphony beyond praise by Spohr. Mozart, coming to the rescue of Michael Haydn, who was prevented by illness from completing a set of six commissioned by the archbishop of Salzburg, wrote two for violin and viola, which profit greatly by the extra lower fifth and which are written with great zest and a reckless disregard (justified by personal knowledge) of the chance that the archbishop might detect their difference from the dutiful efforts of brother Michael.

Trios for two violins and any kind of bass but the viola, are ominously suggestive of a return to, or non-emergence from, the continuo method; and indeed it may be doubted whether any Italian composer before Cherubini (*q.v.*) ever did quite emerge therefrom. Trios for violin, viola and violoncello are a very different matter. They represent the problem of the string quartet intensified into a *tour-de-force*. Mozart's great example, the divertimento in E flat, is in all its six movements on a scale and a plane of thought that its title vainly belies. It inspired Beethoven to one of his biggest early works, the Trio op. 3; and the success of this encouraged Beethoven to write the three string Trios op. 9, of which the first, in G major, and the third, in C minor, are bolder in conception and execution than even the largest of the six string quartets, op. 18, and not less sonorous than any string quartet written before or since.

The string quartet represents the normal apparatus for a chamber music work of homogeneous tone. String quintets are usually produced in Mozart's way by doubling the viola. Doubling the violoncello, as in Schubert's great C major quintet, produces a very rich tone and sets the first violoncello free to soar into the cantabile region without (as in other quintets and in quartets) depriving the ensemble of a deep bass. Sextets, for two violins, two violas and two violoncellos, are represented in the two great works of Brahms. Octets for strings show signs of clotting into an orchestral style. Spohr hit upon the device of dividing the eight into antiphonal quartets; and his four double quartets are much nearer to the true style of chamber music than his string quartets, where his lower parts have the simplicity of early Haydn while the first violin plays a concerto above them. Mendelssohn in the wonderful octet which he wrote at the age of 16, does not find Spohr's simple antiphonal scheme worth the trouble of specially grouping the players when he can use 255 different combinations of the eight without enquiring how they are seated.

As for the semi-orchestral borderland of septets and octets in which several wind instruments join and a double-bass adds depth without any normal capacity to rise into cantabile or solo work, this borderland (inhabited by Beethoven's septet, Schubert's octet and many glorious serenades and divertimenti of Mozart) has a fascinating aesthetic of its own. Wind instruments by themselves are happiest in pairs, as their tones contrast too sharply otherwise to blend at all, though Reicha, who composed regularly for two hours before breakfast every morning, ground out over 100 quintets for flute, oboe, clarinet, horn and bassoon, all admirably euphonious, if they are up to the sample passages quoted by him in his treatise on composition. It is unreasonable to blame Mozart's glorious serenade for 13 wind instruments for sounding like a military band; we ought rather to wish that a military band could sound like a Mozart serenade.

Modern Tendencies.—Nothing remains to be said about chamber music, classical or modern, apart from the general tendencies of the art. The exclusive prevalence of sonata form in the classics is a result of the fact that when several persons assemble to play together they prefer to make the most of their opportunity. Smaller works are liable to be overlooked; how otherwise can we account for the fact that most musicians do not realize the existence of three quiet minutes of the most delicate writing in Beethoven's third manner, the quintet-fugue op. 137? A spirited

capriccio and a pretty fugue by Mendelssohn have dropped out of sight for no other reason, while the andante and scherzo published with them and Schubert's allegro in C minor have roused interest as fragments of full sized works.

In modern times the sonata form no longer obstructs the view of other possibilities. Mr. W. W. Cobbett's prize competitions stimulated English composers to the production of fantasies in terse continuous-movement forms. Less important are the numerous experiments in the use of the human voice without words in an otherwise instrumental scheme. Nature responds cattishly to the pitchfork. Saint-Saëns has a charming manner which puts the trumpet on its best behaviour in his amusing septet. The trombone and side-drums in the chamber music of Stravinsky will do well enough in a very smart house-party where all the conversation is carried on in an esoteric family slang and the guests are expected to enjoy booby-traps. Very different is the outlook of some of our younger masters such as Hindemith, Jarnach, and others whose renunciation of beauty is in itself a youthfully romantic gesture, and is accompanied by endless pains in securing adequate performance. The work of masterly performers can indeed alone save the new ideas from being swamped in a universal dullness which no external smartness can long distinguish from that commemorated in the Dunciad.

(D. F. T.)

CHAMBER ORCHESTRA, a small orchestra of some 20 or 30 players suited to the performance of works of the smaller and lighter order.

CHAMBERS, EPHRAIM (d. 1740), English encyclopaedist, was born at Kendal, Westmorland, and apprenticed to a globe-maker in London. The first edition of his *Universal Dictionary of Arts and Sciences* appeared by subscription in 1728, in two vols., fol., dedicated to the king. The *Encyclopédie* of Diderot and d'Alembert owed its inception to a French translation of Chambers's work. In addition to the *Cyclopaedia,* Chambers wrote for the *Literary Magazine* (1735–36), and translated the *History and Memoirs of the Royal Academy of Sciences at Paris* (1742), and the *Practice of Perspective* from the French of Jean Dubreuil. He died on May 15, 1740.

CHAMBERS, GEORGE (1803–1840), English marine painter, born at Whitby, Yorkshire, was the son of a seaman, and for several years he pursued his father's calling. He then took lessons from a drawing-master, and found a ready sale for small and cheap pictures of shipping. Coming to London, he was employed by Thomas Horner to assist in painting the great panorama of London for the Colosseum (the exhibition building in Regent's park, demolished *c.* 1860). His best works represent naval battles. Two of these—the "Bombardment of Algiers in 1816," and the "Capture of Porto Bello"—are in Greenwich hospital. He died on Oct. 28, 1840.

A *Life,* by John Watkins, was published in 1841.

CHAMBERS, ROBERT (1802–1871), Scottish author and publisher, was born at Peebles on July 10, 1802. A small circulating library in the town, and a copy of the *Encyclopædia Britannica* which his father had purchased, furnished the boy with stores of reading of which he eagerly availed himself. Long afterwards he wrote of his early years—"Books, not playthings, filled my hands in childhood. At 12 I was deep, not only in poetry and fiction, but in encyclopaedias." The family removed to Edinburgh in 1813, and in 1818 Robert began business at 16 as a bookstall-keeper in Leith Walk. In 1819 his elder brother William had begun a similar business, and the two eventually united as partners in the publishing firm of W. and R. Chambers. Robert Chambers was an enthusiast for the history and antiquities of Edinburgh, and his *Traditions of Edinburgh* (1824), secured for him the personal friendship of Sir Walter Scott. A *History of the Rebellions in Scotland from 1638 to 1745* (1828), and numerous other works followed.

At the beginning of 1832 William Chambers started a weekly publication under the title of *Chambers's Edinburgh Journal* (known since 1854 as *Chambers's Journal of Literature, Science and Arts*), which speedily attained a large circulation.

Among the numerous works of which Robert was in whole or in part the author, the *Biographical Dictionary of Eminent Scotsmen* (Glasgow, 1832–35), the *Cyclopaedia of English Literature* (1844), the *Life and Works of Robert Burns* (1851), *Ancient Sea Margins* (1848), the *Domestic Annals of Scotland* (1859–61) and the *Book of Days* (1862–64) were the most important. *Chambers's Encyclopaedia* (1859–68), with Dr. Andrew Findlater as editor, was carried out under the superintendence of the brothers (*see* ENCYCLOPAEDIA).

As a geologist, Robert Chambers published *Tracings of the North of Europe* (1851) and *Tracings in Iceland and the Faröe Islands* (1856). His knowledge of geology was one of the principal grounds on which the authorship of the *Vestiges of the Natural History of Creation* (1843–46) was eventually assigned to him. The *Book of Days,* a miscellany of popular antiquities, was his last publication. He died at St. Andrews on March 17, 1871.

His brother, WILLIAM CHAMBERS (1800–83), the financial genius of the publishing firm, was born at Peebles, on April 16, 1800. He laid the city of Edinburgh under the greatest obligations by his public spirit and munificence. As lord provost he procured the passing in 1867 of the Improvement Act, which led to the reconstruction of a great part of the Old Town, and at a later date he proposed and carried out, largely at his own expense, the restoration of the noble and then neglected church of St. Giles, making it in a sense "the Westminster Abbey of Scotland." This service was fitly acknowledged by the offer of a baronetcy, which he did not live to receive, dying on May 20, 1883, three days before the reopening of the church. He was the author of a history of St. Giles, of a memoir of himself and his brother (1872), and of many other useful publications. On his death in 1883 Robert Chambers (1832–88), son of Robert Chambers, succeeded as head of the firm, and edited the *Journal* until his death. His eldest son, Charles Edward Stuart Chambers (b. 1859), became editor of the *Journal* and chairman of W. & R. Chambers, Ltd.

See also *Memoir of Robert Chambers, with Autobiographic Reminiscences of William Chambers* (1872), the 13th ed. of which (1884) has a supplementary chapter; Alexander Ireland's preface to the 12th ed. (1884) of the *Vestiges of Creation;* the *Story of a Long and Busy Life* (1884), by William Chambers; and some discriminating appreciation in James Payn's *Some Literary Recollections* (1884), chapter v. The *Select Writings of Robert Chambers* were published in seven vols. in 1847, and a complete list of the works of the brothers is added to *A Catalogue of Some of the Rarer Books . . . in the Collection of C. E. S. Chambers* (Edinburgh, 1891).

CHAMBERS, SIR WILLIAM (1726–1796), British architect, was the grandson of a rich merchant who had financed the armies of Charles XII., but was paid in base money, and whose son remained in Sweden many years endeavouring to obtain redress. In 1728 the latter returned to England and settled at Ripon, where William, who was born in Stockholm, was educated. At the age of 16 he became supercargo to the Swedish East India Company, and, voyaging to Canton, made drawings of Chinese architecture, furniture and costume which served as basis for his *Designs for Chinese Buildings,* etc. (1757). Two years later he quitted the sea to study architecture seriously, and spent a long time in Italy, devoting special attention to the buildings of classical and Renaissance architects. He also studied under Clérisseau in Paris, with whom, and with the sculptor Wilton, he lived at Rome. In 1755 he returned to England where his first important commission was a villa for Lord Bessborough at Roehampton, but he made his reputation by the grounds he laid out and the buildings he designed at Kew, among them being the pagoda in the gardens, between 1757 and 1762 for Augusta, princess dowager of Wales. He published (1759) a *Treatise on Civil Architecture* and in 1772 a *Dissertation on Oriental Gardening,* which attempted to prove the inferiority of European to Chinese landscape gardening. As a furniture designer and internal decorator he is credited with the creation of that "Chinese Style" which was for a time furiously popular, although Thomas Chippendale (*q.v.*) had published designs in that manner at a somewhat earlier date. He became architect to the king and queen, comptroller of his majesty's works, and afterwards surveyor-general. In 1775 he was appointed architect of Somerset House, his greatest monument, at a salary of £2,000 a year. He

also designed town mansions for Earl Gower at Whitehall and Lord Melbourne in Piccadilly, built Charlemont House, Dublin, and Duddingston House, near Edinburgh. He designed the market house at Worcester, was employed by the earl of Pembroke at Wilton, by the duke of Marlborough at Blenheim, and by the duke of Bedford in Bloomsbury. Although his practice was mainly classic, he made Gothic additions to Milton Abbey in Dorset. Sir William numbered among his friends Dr. Johnson, Goldsmith, Sir Joshua Reynolds, David Garrick and Dr. Burney.

CHAMBERS, in law, the rooms of counsel or of judges or judicial officers who deal with questions of practice and other matters not of sufficient importance to be dealt with in court. It is doubtful at what period the practice of exercising jurisdiction "in chambers" commenced in England; there is no statutory sanction before 1821, though the custom can be traced back to the 17th century. An Act of 1821 provided for sittings in chambers in vacation, and an Act of 1822 empowered the sovereign to call upon the judges by warrant to sit in chambers on as many days in vacation as should seem fit, while the Law Terms Act, 1830, defined the jurisdiction to be exercised at chambers. The Judges' Chambers Act, 1867, was the first Act, however, to lay down proper regulations for chamber work, and the Judicature Act, 1873, preserved that jurisdiction and gave power to increase it as might be directed or authorized by rules of court to be thereafter made. (*See* PRACTICE AND PROCEDURE.)

CHAMBERSBURG, a borough of Franklin county, Pennsylvania, U.S.A., on an elevated site in the broad and fertile Cumberland valley, 52 mi. S.W. of Harrisburg; it is on federal highways 11 and 30, and is served by the Pennsylvania and the Western Maryland railways. Pop. (1950) 17,205. It is the county seat and has large grain elevators, food processing plants and various other industries.

Wilson college, a Presbyterian institution for women, chartered in 1869, is there. Chambersburg was founded in 1730 by Benjamin Chambers. He built a stone fort after Gen. Edward Braddock's defeat (1755) and surrounded it with a stockade as a defense against the Indians. At Chambersburg Gen. Robert E. Lee massed his troops for his attack on Gettysburg. On July 30, 1864, a large part of the borough was burned by Confederates. The birthplace of Pres. James Buchanan is near by, and 10 mi. E. is Caledonia State Forest reserve.

CHAMBERS OF COMMERCE: *see* TRADE ORGANIZATION.

CHAMBER SYMPHONY, a musical composition written for a small orchestra exceeding in numbers the largest of the ordinary chamber music combinations (octet or nonet) but not approaching those of a full orchestra, and confined usually to a single instrument in each class. Such a work is Franz Schreker's Kammersymphonie for 23 solo instruments; another has been written by Schönberg.

CHAMBÉRY, a city of France, capital of the department of Savoie, pleasantly situated on the Leisse, in a fertile valley among the Alps, 79 mi. by rail S.S.W. of Geneva. Pop. (1946) 29,975. It was formerly capital of the duchy of Savoy, and remains, with its quiet narrow streets and its girdle of boulevards, a typical old provincial capital of France. The neighbouring country is dotted with summer resorts, and the town is a favourite centre for excursions. Chambéry grew up around a castle of the counts of Savoy, who resided there in the 13th, 14th and 15th centuries. A Roman station (Lemincum) in the vicinity has given its name to the rock of Lémenc, which overlooks the town on the north. Between 1536 and 1713 Chambéry was several times occupied by the French; in 1742 it was captured by a Franco-Spanish army; and in 1792 it was occupied by the Republican forces, and became the capital of the department of Mont Blanc. Restored to the house of Savoy by the treaties of Vienna and Paris, it was again surrendered to France in 1860.

The principal buildings are the cathedral, dating from the 14th and 15th centuries; the Hôtel-Dieu, founded in 1647, and the castle, a modern building serving as the prefecture, with only a great square tower belonging to the original structure; Chambéry is the seat of an archbishop (raised from a bishopric in 1817) and of a superior tribunal. It has long been famous as a regional culture-centre, and possesses an academy (1819) and several learned societies. Local benefactions have profited greatly from the fortune of General Boigne (1751–1830), amassed in India. Among the manufactures are silk-gauze, lace, leather and hats; there are also aluminium-works.

CHAMBORD, HENRI CHARLES FERDINAND MARIE DIEUDONNE, COMTE DE (1820–1883), the "King Henry V." of the French legitimists, was born in Paris on Sept. 29, 1820, son of the duc de Berry, the elder son of the comte d'Artois (afterwards Charles X.), and princess Caroline Ferdinande Louise of Naples. Born seven months after the assassination of his father, he was hailed as the "enfant du miracle," and was made the subject of one of Lamartine's most famous poems. He was created duc de Bordeaux, and in 1821, as the result of a subscription organized by the Government, received the château of Chambord. His education was inspired by detestation of the French Revolution and its principles. After the revolution of July, Charles X. vainly endeavoured to save the Bourbon cause by abdicating in his favour and proclaiming him king under the title of Henry V. (Aug. 2, 1830). The comte de Chambord accompanied his grandfather into exile, and resided successively at Holyrood, Prague and Görz. The death of his grandfather, Charles X., in 1836, and his uncle, the duc d'Angoulême, in 1844, left him the last male representative of the elder branch of the Bourbon family; and his marriage with the archduchess Maria Theresa, eldest daughter of the duke of Modena (Nov. 7, 1846), remained without issue. The title to the throne thus passed to the comte de Paris, as representative of the Orleans branch of the house of Bourbon, and the history of the comte de Chambord's life is largely an account of the efforts made to unite the Royalist party by effecting a reconciliation between the two princes.

Though he continued to hold an informal court, both on his travels and at his castle of Frohsdorf, near Vienna, yet he allowed the revolution of 1848 and the *coup d'état* of 1851 to pass without any decisive assertion of his claims. It was the Italian war of 1859, with its menace to the pope's independence, that roused him at last to activity, thus making common cause with the Church. The Royalists now began an active campaign against the Empire. On Dec. 9, 1866, Chambord addressed a manifesto to Gen. Saint-Priest, in which he declared the cause of the pope to be that of society and liberty, and held out promises of retrenchment, civil and religious liberty "and above all honesty." Again, on Sept. 4, 1870, after the fall of the Empire, he invited Frenchmen to accept a Government "whose basis was right and whose principle was honesty," and promised to drive the enemy from French soil. Fortune favoured him. The elections placed the Republican party in a minority in the National Assembly; the abrogation of the law of exile against the royal family permitted him to return to his castle of Chambord: and it was thence that on July 5, 1871, he issued a proclamation, in which for the first time he publicly posed as king, and declared that he would never abandon the white standard of the Bourbons, "the flag of Henry IV., Francis I., and Joan of Arc," for the tricolour of the Revolution. He again quitted France, and answered the attempts to make him renounce his claims in favour of the comte de Paris by the declaration (Jan. 25, 1872) that he would never abdicate. A constitutional programme, signed by some 280 members of the National Assembly was presented for his acceptance, but without result. The fall of Thiers in May 1873, however, offered an opportunity to the Royalists by which they hastened to profit. The comte de Paris and the prince de Joinville journeyed to Frohsdorf, and were formally reconciled with the head of the family (Aug. 5). The Royalists were united, the premier (the duc de Broglie) an open adherent, the president (MacMahon) a benevolent neutral. MM. Lucien Brun and Chesnelong were sent to interview the comte de Chambord at Salzburg, and obtain the definite assurances that alone were wanting. They returned with the news that he accepted the principles of the French Revolution and the tricolour flag. But a letter to Chesnelong, dated Salzburg, Oct. 27, declared that he had been misunderstood: he

would give no guarantees; he would not inaugurate his reign by an act of weakness, nor become "le roi légitime de la Révolution." "Je suis le pilote nécessaire," he added, "le seul capable de conduire le navire au port, parce que j'ai mission et autorité pour cela." A last effort was made in the national assembly in June 1874 by the duc de la Rochefoucauld-Bisaccia, who formally moved the restoration of the monarchy. The comte de Chambord on July 2 issued a fresh manifesto, which added nothing to his former declarations. The motion was rejected by 272 to 79, and on Feb. 25, 1875, the assembly definitely adopted the republic as the national form of government. The count died at Frohsdorf on Aug. 24, 1883.

See *Manifestes et programmes politiques de M. le comte de Chambord, 1848–73* (1873), and *Correspondance de la famille royale et principalement de Mgr. le comte de Chambord avec le comte de Bouillé* (1884). Of the literature relating to him, mention may be made of *Henri V. et la monarchie traditionnelle* (1871); *Le Comte de Chambord étudié dans ses voyages et sa correspondance* (1880); H. de Pène, *Henri de France* (1885).

CHAMBORD, a village of central France, in the department of Loir-et-Cher, on the left bank of the Cosson, 10 mi. E. by N. of Blois. Pop. (1936) 165. The village stands in the park of Chambord, which is enclosed by a wall 22 mi. in circumference. The celebrated château (*see* ARCHITECTURE) forms a parallelogram flanked at the angles by round towers and enclosing a square block of buildings, the façade of which forms the centre of the main front. There is a chapel of the 16th century and a famous double staircase. The château was originally a hunting-lodge of the counts of Blois, the rebuilding of which was begun by Francis I in 1526, and completed under Henry II. It was the residence of several succeeding monarchs, and under Louis XIV considerable alterations were made. In the same reign Molière's *Monsieur de Pourceaugnac* and *Le Bourgeois gentilhomme* were performed here for the first time. Stanislas of Poland lived at Chambord, which was bestowed by his son-in-law, Louis XV, upon Marshal Saxe. It was given by Napoleon to Marshal Berthier, from whose widow it was purchased by subscription in 1821, and presented to the duc de Bordeaux, who assumed the title of comte de Chambord. On his death it came by bequest to the family of Parma. The estate was sequestrated in 1914.

CHAMBRE ARDENTE, the term for an extraordinary court of justice in France, mainly held for the trials of heretics (Fr. "burning chamber"). These courts were originated by the Cardinal of Lorraine, the first of them meeting in 1535 under Francis I. The *Chambre Ardente* co-operated with an inquisitorial tribunal also established by Francis I, the duty of which was to discover cases of heresy and hand them over for final judgment to the *Chambre Ardente*. The court was abolished in 1682.

See N. Weiss, *La Chambre Ardente* (Paris, 1889).

CHAMELEON, the common name of members of one of the most remarkable of the families of lizards, Chameleontidae. Because of the similar ability to change colour, the same name is misapplied to American lizards of the genus *Anolis* (Iguanidae). The great majority of chameleons are referable to the genus *Chamaeleo* (containing about 70 species), the remaining genera, *Rhampholeon, Leandria* and *Brookesia,* containing only a few dwarfed forms. The group is found in Africa and Madagascar, Arabia, southern India and Ceylon. The grasping feet are formed by the fusion of the digits into two opposable bundles, the two outer digits being opposed to the three inner on the forelimb and vice versa on the hindlimb, and, like the prehensile tail, are correlated with climbing habits. The eyes are large and independently movable, but the eyelids are fused into one circular fold which leaves only the pupil visible; the eyes can also, unlike those of other reptiles, be focussed upon one spot, giving the binocular vision necessary for the nice appreciation of distances required in the use of the tongue. This organ is very large, club-shaped and provided with a sticky secretion at its tip; the basal portion is narrow and composed of very elastic fibres, which, when the tongue is not in use, are telescoped over the elongated copular piece of the hyoid, which acts as a support. By means of its muscular mechanism the tongue can be shot out to a remarkable distance, somewhat exceeding the length of the body; the elasticity of the basal fibres assists in its rapid withdrawal. It is by means of this extraordinary mechanism that the chameleon secures its prey; flies and other insects are deliberately stalked until within range, then out shoots the tongue and the victim is withdrawn adhering to its sticky tip.

THE TRUE CHAMELEONS. ABOVE: THE COMMON CHAMELEON OF THE MEDITERRANEAN REGION. BELOW: THREE DIVERSE TYPES OF AFRICAN CHAMELEONS

The ability of chameleons to change colour is proverbial, but their powers are usually exaggerated and are quite equalled by those of some other lizards. Change of colour is partly reflex in response to emotional stimuli and partly controlled through the eye; changes in the intensity of light, change of temperature and emotion produce marked and characteristic changes, but there is little direct response to the colour of the environment. The normal colour of the common chameleon may be gray-green with innumerable small dark specks and with rows of pale-brown patches on the sides of the body; in the dark at normal temperatures the colour fades to a cream-colour with irregular yellow spots, but exposure to hot sunlight causes the whole animal to darken until it may be uniformly dull black. High temperatures without direct sunlight usually produce greens and low temperatures dull grays; excitement and fright bring paler shades with brown patches and yellow spots, while anger causes the lighter areas to darken.

Propagation is in most cases by means of eggs; these are small, oval, white in colour and provided with a tough parchmentlike shell. They are buried by the mother and left to be incubated by the heat of the sun. A few species, *e.g.*, the dwarf chameleon of South Africa (*C. pumilus*), retain the eggs within the body until they hatch, so that the young are born alive.

An extraordinary feature of the group is a tendency toward the production of excrescences on the head. Many species have the occiput produced backwards into a pointed casque and this may assume extraordinary dimensions; but the most remarkable developments are the horns of some of the tropical African and Malagasy species. In different forms there may be one, two, three or four horns or a single, flexible, dermal flap on the tip of the snout; in some species these appendages occur only on the male but in others they are present on both sexes.

(D. M. S. W.; X.)

CHAMFER, CHAMPFER or **CHAUMFER,** an architectural term for the cutting off of the edges of the corners of a beam, post or other similar form, and also the slanting surface so produced. Chamfers are frequently hollowed or moulded When the chamfer does not run the full length of the member that it decorates, the shoulder, diagonal cut or moulding against which it stops is known as a stop chamfer.

CHAMFORT, SEBASTIEN ROCH NICOLAS (1741–1794), French wit and man of letters, was born at a little village near Clermont in Auvergne, the son of a grocer named Nicolas. Educated as a free scholar at the Collège des Grassins, he lived from hand to mouth in Paris mainly on the hospitality of people who were only too glad to give him board and lodging in exchange for the pleasure of the conversation for which he was famous. Thus Mme. Helvétius entertained him at Sèvres for some years. He had a great success with his comedies *La Jeune Indienne* (1764) and *Le Marchand de Smyrne* (1770). In 1775, while taking the waters at Barèges, he met the duchesse de Grammont, sister of Choiseul, through whose influence he was introduced at court. In 1776 his poor tragedy *Mustapha et Zeangir* was played at Fontainebleau before Louis XVI and Marie Antoinette; the king gave him a further pension of 1,200 livres, and the prince de Condé made him his secretary. But he was a Bohemian naturally

and by habit, and the restraints of the court irked him. In 1781 he was elected to the Academy; in 1784, through the influence of Calonne, he became secretary to the king's sister, Mme. Elizabeth, and in 1786 he received a pension of 2,000 livres from the royal treasury. He was thus once more attached to the court, and made himself friends in spite of the reach and tendency of his unalterable irony; but he quitted it for ever after an unfortunate and mysterious love affair, and was received into the house of M. de Vaudreuil. Here in 1783 he had met Mirabeau, with whom he remained to the last on terms of intimate friendship.

The outbreak of the Revolution made a profound change in Chamfort's life. Theoretically he had long been a republican, and he now devoted all his small fortune to the revolutionary propaganda. Until Aug. 31, 1791, he was secretary of the Jacobin club; he entered the Bastille among the first of the storming party. He worked for the *Mercure de France*, collaborated with Ginguené in the *Feuille villageoise*, and drew up for Talleyrand his *Adresse au peuple français*.

With the reign of Marat and Robespierre, however, his uncompromising Jacobinism grew critical, and with the fall of the Girondins his political life came to an end. But he could not restrain the tongue that had made him famous; he no more spared the Convention than he had spared the court. He was imprisoned for a short time, and released; but he had determined to prefer death to a repetition of confinement, and when he was again threatened with arrest he attempted suicide with pistol and with poniard, dictating to those who came to arrest him the well-known declaration: "*Moi, Sebastien-Roch-Nicolas Chamfort, déclare avoir voulu mourir en homme libre plutôt que d'être reconduit en esclave dans une maison d'arrêt,*" which he signed in a firm hand and in his own blood. He lingered on until April 13, 1794 in charge of a gendarme. To the Abbé Sieyès Chamfort had given fortune in the title of a pamphlet ("*Qu'est-ce que le Tiers-État? Tout. Qu'a-t-il? Rien*"), and to Sieyès did Chamfort retail his supreme sarcasm, the famous "*Je m'en vais enfin de ce monde où il faut que le cœur se brise ou se bronze.*" The maker of constitutions followed the dead wit to the grave.

The writings of Chamfort, which include comedies, political articles, literary criticisms, portraits, letters and verses, are colourless and uninteresting. His genius was in conversation. His *Maximes et Pensées* are, after those of La Rochefoucauld, the most brilliant and suggestive sayings of the 18th century. The aphorisms of Chamfort, less systematic and psychologically less important than those of La Rochefoucauld, are as significant in their violence and iconoclastic spirit of the period of storm and preparation that gave them birth as the *Réflexions* in their exquisite restraint and elaborate subtlety are characteristic of the tranquil elegance of their epoch; and they have the advantage in richness of colour, in picturesqueness of phrase, in passion, in audacity. Sainte-Beuve compares them to "well-minted coins that retain their value," and to keen arrows that *arrivent brusquement et sifflent encore.*

The *Oeuvres complètes de Nicolas Chamfort* appeared at Paris, 5 vols. (1824–25), selections one vol. (1852), with a biographical and critical preface by Arsène Houssaye and *Oeuvres choisies*, with a preface and notes by M. de Lescure (1879). *See* also Sainte-Beuve, *Causeries du Lundi*; M. Pellisson, *Chamfort, étude sur sa vie* (1895).

CHAMFRON or **CHANFRIN.** A horse's forehead, more particularly the piece of armour which covered the front of a barded horse.

CHAMIER, FREDERICK (1796–1870), English novelist, was the son of an Anglo-Indian official, and served in the navy from 1809 to 1856. Captain Chamier wrote several popular sea-stories, including *The Life of a Sailor* (1832), *Ben Brace* (1836), *The Arethusa* (1837), *Jack Adams* (1838), *Tom Bowling* (1841), and *Jack Malcolm's Log* (1846). He also edited and brought down to 1827 James's *Naval History* (1837).

CHAMILLART, MICHEL (1652–1721), French statesman, minister of Louis XIV. In 1690 he was made intendant of finances, and on Sept. 5, 1699, the king appointed him controller-general of finances, and on Jan. 7, 1700, minister of war. From the first Chamillart's position was a difficult one. The deficit amounted to more than 53 million livres, and the credit of the state was almost exhausted. In Oct. 1706 he showed the king that the debts immediately due amounted to 288 millions, and that the deficit already foreseen for 1707 was 160 millions. In Oct. 1707 he saw with consternation that the revenue for 1708 was already entirely eaten up by anticipation, so that neither money nor credit remained for 1708. In these conditions Chamillart resigned his office of controller-general. Public opinion attributed to him the ruin of the country, though he had tried in 1700 to improve the condition of commerce by the creation of a council of commerce. As secretary of state for war he had to place in the field the army for the War of the Spanish Succession, and to reorganize it three times, after the great defeats of 1704, 1706 and 1708. With an empty treasury he succeeded only in part, and he frankly warned the king that the enemy would soon be able to dictate the terms of peace. He resigned office in 1709, and died on April 14, 1721.

Esnault, *Michel Chamillart, contrôleur général et secrétaire d'état de la guerre, correspondance et papiers inédits* (1885); A. de Boislisle *Correspondance des contrôleurs généraux* (vol. ii., 1883); M. Langlois, *Louis XIV. et la cour. D'après trois témoins nouveaux: Bélise Beauvillier, Chamillart.* (1926).

CHAMINADE, CÉCILE (1861–1944), French composer, was born in Paris on Aug. 8, 1861. She studied in Paris, her musical talent being shown at the age of eight by the writing of some church music which attracted Bizet's attention; and at eighteen she came out in public as a pianist. Her own compositions, both songs (in large numbers) and instrumental pieces, are melodious and effective and have enjoyed great popularity.

CHAMISE (*Adenostoma fasciculatum*). A North American shrub of the rose family (Rosaceae), called also chamiso, found in the chaparral belt on foothills and mountain slopes in California, ranging up to 5,000 ft. altitude. It grows from 2 ft. to 10 ft. high, with shreddy brown bark; slender twiggy branches; resinous, narrow leaves in bundles or fascicles, and small white flowers in panicled clusters. Chamise is the most abundant and characteristic small shrub of the higher foothills west of the Sierra Nevada, where, between the lower foothills and the yellow pine belt, it often forms a distinct zone called chamisal. (*See* CHAPARRAL.)

CHAMISSO, ADELBERT VON (LOUIS CHARLES ADELAIDE DE) (1781–1838), German poet and botanist, was born at the château of Boncourt in Champagne, the ancestral seat of his family. Driven from France by the revolution, his parents settled in Berlin, where in 1796 young Chamisso obtained the post of page-in-waiting to the queen, and in 1798 entered a Prussian infantry regiment as ensign. In close collaboration with Varnhagen von Ense, he founded in 1803 the *Berliner Musenalmanach*, in which his first verses appeared. Although the enterprise was a failure, it brought him to the notice of literary celebrities. He left the army in 1808, and in 1810 joined the charmed circle of Mme. de Staël, following her in her exile to Coppet in Switzerland. In 1813 he wrote the prose narrative *Peter Schlemihl*, the man who sold his shadow. The most famous of all his works, it has been translated into most European languages (English by W. Howitt). In 1815 Chamisso was appointed botanist to the Russian ship "Rurik," which Otto von Kotzebue commanded on a scientific voyage round the world. He published his diary (*Tagebuch*) of this expedition in 1821. In 1818 he became custodian of the botanical gardens in Berlin. From 1829 he brought out the *Deutsche Musenalmanach*, in which his later poems were mainly published. He died on Aug. 21, 1838.

As a scientist Chamisso wrote *Bemerkungen und Ansichten*, and *Übersicht der nutzbarsten und schädlichsten Gewächse in Norddeutschland* (1829). His *Frauenliebe und -leben* (1830), a cycle of lyrical poems, which was set to music by Schumann, were particularly famous. Noteworthy are also *Schloss Boncourt* and *Salas y Gomez*. In the lyrical expression of the domestic emotions he displays a fine felicity, and he knew how to treat with true feeling a tale of love or vengeance. *Die Löwenbraut* may be taken as a sample of his weird and powerful simplicity; and *Vergeltung* is remarkable for a pitiless precision of treatment.

The first collected edition of Chamisso's works was edited by J. E. Hitzig (6 vols., 1836; 6th ed., 1874); there are also excellent editions

by M. Koch (1883) and O. F. Walzel (1892). On Chamisso's life *see* J. E. Hitzig, "Leben und Briefe von Adelbert von Chamisso" (in the *Gesammelte Werke*); K. Fulda, *Chamisso und seine Zeit* (1881); G. Hofmeister, *Adelbert von Chamisso* (1884); and E. du Bois-Reymond, *Adelbert von Chamisso als Naturforscher* (1889).

CHAMKANNI, a small tribe of Ghoria Khel Pathans in Kurram, Afghanistan.

CHAMOIS, the Franco-Swiss name of a hollow-horned ruminant known in German as *Gemse* or *Gemsbok;* scientifically, *Rupicapra rupicapra.* It is the only species in the genus, though every European range possesses a local race. It is the type of the tribe *Rupicaprini,* which includes several goatlike genera (*see* BOVIDAE). About the size of a roebuck, with a short tail, it is distinguished by the vertical, backwardly directed horns in both sexes, though these are larger in the male. Though differing in the shade of their hair, all the various races have black and white face markings and a black tail and dorsal stripe. The alpine race is chestnut brown in summer, lighter and grayer in winter. A thick underfur is developed in the cold weather.

BY COURTESY OF E.

CHAMOIS, A GOAT ANTELOPE

Chamois live in small herds, but the old males join these only during the rutting season (October), when they engage in fierce contests with each other. The period of gestation is 20 weeks, and the usual number of offspring is one. In summer the animals ascend to the snow line, being exceeded in the loftiness of their haunts only by the ibex. In winter they descend to wooded regions. Chamois hunting is a favourite sport of the Swiss and Tirolese and of amateurs from all countries. As a result of this, the chamois has become rare in many of its old haunts, but it is now preserved in the Swiss National park in the Engadine. Exceedingly wary and astonishingly agile, the animal is very difficult of approach. It feeds in summer on mountain herbs and flowers, in winter on the young shoots of the pine.

The skin is very soft and is made into the original "shammy" leather, though this is also made from the skins of other animals. The flesh is prized as venison. During the 20th century the chamois was successfully introduced from Austria into New Zealand.

CHAMOMILE or CAMOMILE FLOWERS, the flower heads of *Anthemis nobilis* (family Compositae), a herb indigenous to western Europe. It is cultivated for medicinal purposes in Surrey, at several places in Saxony and in France and Belgium, that grown in England being much more valuable than any of the other chamomiles. In the wild plant the florets of the ray are ligulate and white and contain pistils only, those of the disk being tubular and yellow; but under cultivation the whole of the florets tend to become ligulate and white, in which state the flower heads are said to be double.

The flower heads have a warm aromatic odour, which is characteristic of the entire plant, and a very bitter taste. In addition to a bitter extractive principle, they yield a volatile liquid, which on its first extraction is of a pale blue colour, but becomes a yellowish brown on exposure to light. It has the characteristic odour of the flowers and consists of a mixture of butyl and amyl angelates and valerates. Chamomile is used in medicine in the form of its volatile oil.

Wild chamomile is *Matricaria chamomilla,* a weed common in waste and cultivated ground especially in the southern counties of England. It has somewhat the appearance of true chamomile, but a fainter scent.

CHAMONIX-MONT-BLANC, a well-known alpine tourist resort, in the department of Haute-Savoie, southeast France. Pop. (1946) 3,642.

The valley of Chamonix runs from northeast to southwest and is watered by the Arve, which rises in the Mer de Glace. On the southeast towers the snowclad chain of Mont Blanc, and on the northwest the rugged chain of the Brévent and of the Aiguilles Rouges.

Chamonix (3,416 ft.) is the best starting point for the exploration of the glaciers of the Mont Blanc chain, as well as for the ascent of Mont Blanc itself. It is connected with Geneva by a railway (55 mi.).

The valley is first heard of about 1091, when it was granted by the count of the Genevois to the great Benedictine house of St. Michel de la Cluse, near Turin, which, by the early 13th century, had established a priory there. In 1786 the inhabitants bought their freedom from the canons of Sallanches, to whom the priory had been transferred in 1519. In 1530 the count of the Genevois granted the privilege of holding two fairs a year. The tourist industry dates from the 18th century, but its development is modern.

The first party to publish (1744) an account of its visit was that of R. Pococke, W. Windham and other Englishmen who visited the Mer de Glace in 1741.

CHAMPAGNE, an ancient province of France, bounded north by Liège and Luxembourg; east by Lorraine; south by Burgundy; and west by Picardy and Ile de France. It forms the modern departments of Ardennes, Marne, Aube and Haute Marne, with part of Aisne, Seine-et-Marne, Yonne and Meuse. Its name is derived from the immense plains near Reims, Châlons and Troyes. The province was constituted by joining to the countship of Champagne the ecclesiastical duchies of Reims and Langres and the ecclesiastical countship of Châlons. From 1152 to 1234 the countship of Champagne reckoned among its dependencies the countship of Blois and Chartres, of which Touraine was a fief, and the countship of Sancerre and various scattered fiefs in the Bourbonnais and in Burgundy. The countships of Troyes and Meaux were also absorbed into this amalgamation of territories which became known as the "countship of Champagne and Brie." (*See* TROYES.) (A. LO.)

The counts of Champagne were descendants of Odo I (Odo II of Blois; *see* BLOIS, COUNTSHIP OF), who acquired the title in 1019 or 1020. The most famous of these counts were Theobald or Thibaut II (1125–52), already count of Blois (as Theobald IV) and Meaux, one of the most powerful barons of his time; Henry I the Liberal (1152–81; son-in-law of Louis VII of France), who went on the crusade in 1178 and was taken prisoner by the Turks; Henry II (1181–97), who, reaching the Holy Land in 1190, married Isabella, widow of Conrad, marquis of Montferrat, and became king of Jerusalem; and, most famous of all, Theobald IV (*see* THIBAUT [1201–53], son of Theobald III [1197–1201] and Blanche of Navarre). Theobald IV took part in the expedition of Louis VIII of France against the Albigenses (1226), came into prominence in the first years of St. Louis's reign, succeeded to the throne of Navarre as Theobald I on the death of his maternal uncle Sancho VII (1234) and went on an expedition to the Holy Land in 1239–40. He acquired moreover a reputation as a *poète courtois.* Theobald V (II of Navarre; 1254–70) married Isabella, daughter of St. Louis, and died on his return from the eighth crusade after its failure in Tunis. Henry III (I of Navarre), his brother and successor, died in 1274, leaving an only daughter, Joan of Navarre, who married the heir presumptive to the throne of France, Philip the Fair, in 1284 and became queen of France, dying in 1305. At that time the countship passed to her son, Louis le Hutin, who joined it to the crown on his accession as Louis X in 1314.

The great celebrity of Champagne, in the middle ages, lay in its fairs, particularly in the 12th and 13th centuries. At the crossing of the roads from Flanders, Germany, Italy and Provence, Champagne was indeed a convenient meeting place for foreigners. Drapers from the north, wool merchants from England, importers of alum, dyes and spices from the Mediterranean ports, dealers in linen and in furs from Germany and leather sellers from Spain and Africa could easily meet there and bargain together. The great fairs lasted 49 days each and were six in number: one at Lagny, one at Bar-sur-Aube, two at Provins and two at Troyes. Each fair opened with a week devoted to the receiving of merchandise; four weeks then were

spent in selling and the last fortnight in the settling of accounts. For this purpose, clearances and transfers of funds came more and more to be used between customers; and thus the fairs became regular banking centres and clearinghouses, where people not connected with business might also do their transactions (*see* BANKING).

These fairs had a special legislation; and special magistrates called "masters of the fairs" had control of the police there. Thanks to the fairs, Champagne, rather a poor region at first because of the nature of its soil, became rich; and this accounts both for the opulence of its towns (particularly under Henry the Liberal and Theobald IV) and for the emancipation of the cities as well as for more violent movements (*communes*) that took place early.

From the beginning of the 14th century, the superiority of Italian shipping and commercial methods brought about the cities' decline.

In the 16th century Champagne played a prominent part, from a military viewpoint, as a frontier province against the territories of the Spanish Habsburgs and was seriously shaken by the wars of religion.

CHAMPAGNE, BATTLES IN. This was the name commonly if vaguely given to a number of long drawn-out offensives on the western front in World War I. Among the principal ones the first was the French attack east of Reims on Sept. 25, 1915, an outline of which will be found in the article on WORLD WAR I.

The simultaneous British offensive at Loos (*q.v.*), north of Lens, was intended to be subsidiary to this, as was also a lesser French offensive south of Lens. Still more important in scale and design was the French offensive west of Reims in April 1917, frequently called the Nivelle offensive. The failure of this ambitious plan for a swift and decisive break-through culminated in mutinies which seriously endangered the fighting efficiency of the French army; only after some months was its morale restored by the sympathetic and prudent leadership of Gen. Pétain.

The Autumn Offensive, 1915.—During the summer of 1915 local attacks had been carried out in the Vosges and Argonne, while preparations were being made for operations on a large scale in Champagne and for a powerful diversion in Artois. The objective in Champagne was the rupture of the German front from Bazancourt to Challerange, so as to outflank their positions to the north of Reims and in the Argonne. It was hoped thus to roll up the eastern part of the German front. Under the direction of Gen. de Castelnau the attack was made by the II. Army (Pétain) with the right of the IV. Army (de Langle de Cary) and the left of the III. Army (Humbert), a total of 35 divisions, or at least 420 battalions, against the German III. Army (Einem), which had at first only 70 battalions, later reinforced to 192. However, the secret of the future offensive was so badly kept that as early as Aug. 15 a German order had foreseen it. The artillery preparation began on Sept. 22, and at 9:15 A.M. on Sept. 25 the assault was launched and penetrated along almost the whole front to a depth of from 2,000 to 4,000yd. reaching even the second position in one sector. But the German command, foreshadowing the method of elastic defence which became famous in 1918, had withdrawn the guns and allowed the lightly held first position to act as a shock-absorber. Progress then became slow and costly.

On Sept. 28 and 29 a part of the second position was carried to the west of Le Mesnil and Navarin farm and a break through was made in a narrow section, but the Germans quickly closed the gap. The French cavalry corps had to retire on the 28th to the rear lines without having been engaged. On the 30th a general order announced the end of the operations with the capture of 25,000 prisoners and 150 guns. Nevertheless, abortive attacks continued until Oct. 8. The Champagne offensive cost the French 80,000 killed and missing and 100,000 sick and wounded. The results were not in due proportion to this sacrifice, mainly because the attacks had lacked the characteristics of surprise, rapidity and continuity, and had been continued too long.

French Offensive on the Aisne, 1917.—The strategical and political controversies which preceded the opening of the allies' offensive campaign of 1917 are dealt with in the article on WORLD WAR I. On the Aisne, the French offensive was to extend from Vailly to Reims. Gen. Pétain, consulted by Nivelle on the proposed action, criticized it freely and refused the leadership, which was entrusted to Gen. Michelet. The V. Army (Masel), which had held this front since 1914, closed on its right to make room for the VI. Army (Mangin), while the X. Army (Duchêne) was in reserve. Nivelle had decided on a rapid attack which aimed at carrying the positions and all the artillery zone at the first assault. This resembled the method twice employed at Verdun. No one raised any serious objection, but Nivelle foretold an immediate exploitation of the success by the X. Army, which should carry it as far to the north as possible. Michelet estimated that the whole operation might be accomplished the first day, or at latest on the morning of the second. He indicated as objectives the foot of the heights to the north of the Ailette, the plain of Laon, and the east of Brimont fort. The only objection was raised by Mangin, who called attention particularly to the importance of good atmospheric conditions. This did not modify Nivelle's wishes, and Michelet exaggerated them by giving such detailed orders that no initiative was left to the army commanders.

The preparation for the offensive was in full swing when the German retreat to the Hindenburg line began. Nivelle's plan had to be modified, the Oise-Somme attack lost all interest and that upon the Aisne alone remained. Mangin called attention to the fact that the retirement had left a right-angled salient about the Laffaux mill and that an attack to the north would be able to take the Chemin des Dames in reverse. The commander-in-chief admitted this and two divisions were devoted to this local operation. In addition it was decided that the IV. Army (Anthoine) should attack the Massif de Moronvilliers, east of Reims. On top of this a political incident led to the retirement of Gen. Lyautey, Minister of War. He was replaced by M. Painlevé, who was hostile to Nivelle's plans. This weakened the confidence of the commander-in-chief's subordinates, and Nivelle went so far as to offer his resignation, which was refused.

The British share of the offensive began on April 9 before Arras. The operations on the Aisne should have begun on April 12, but were put off, first to the 14th, then to the 16th on account of the bad weather. The front of attack measured 25 miles. The VI. Army (Mangin) operated on nearly 10m. with 17 divisions plus a cavalry division and a territorial division, 1,669 guns, of which 823 were heavy or large; the V. Army (Masel) had a nearly similar strength but with 1,967 guns (1,107 heavy or large). The artillery preparation commenced on April 5 and continued until the 15th on account of the postponement of the attack. It sufficed, but its duration permitted the Germans to make suitable dispositions and there was no surprise. On the morning of April 16 the Allies carried the first German line on the whole front. The right and centre of the V. Army gained a depth of 1½ to 2m., but on the left a tank attack, badly conducted, failed with heavy losses and the infantry rapidly came to a standstill on the plateau of Craonne. The right of the VI. Army took the position of Hurtebise and pushed as far as the Ailette, but further east the fighting was desperate and the gain insignificant. In the centre progress was more satisfactory, though difficult. On the left, the commencement was good, but the advance quickly became wild, and at certain points it was practically negligible.

To sum up, although some good results had been obtained the hoped for success had not been won. Badly informed, Nivelle imagined that on the 17th he ought to stop the northern advance of the VI. Army and push the V. Army towards the north-east. This order became delayed, so on the 17th Mangin continued his attacks, notably in the centre, where he made a marked advance on the front Braye en Laonnois-Ostel. The situation having changed Mangin ordered a vigorous pursuit, in spite of the

stopping order. Slow progress was made towards the Chemin des Dames. On the same date (17th) the IV. Army (Anthoine) had made good progress in the Massif de Moronvilliers. Between the 16th and 20th the French captured 21,000 prisoners and 183 guns, and advanced some 5m. on the Aisne front of 7½m. width. Of the 52 German divisions in reserve available on April 1 only 16 remained unengaged. This result was less than had been hoped, but it was nevertheless appreciable and certainly superior to those of preceding offensives.

Unhappily the morale behind the front line was rapidly declining, the losses being greatly exaggerated. Nevertheless, Nivelle continued his operations. The X. Army took up its position on the plateau de Craonne, between the V. and VI. Armies, but on April 27 Michelet wrote that he had not strength enough for a general offensive toward the north and that he proposed to limit himself to local attacks. Nivelle accepted this solution. These operations, rendered more difficult by the unfortunate intervention of politicians, produced very poor results. The IV. Army on May 4 captured the Craonne plateau, and Laffaux mill was carried on the 5th. For several months, however, the X. Army could only with difficulty hold on to the crest of the Chemin des Dames. The French had lost from April 16 to 25, 15,000 dead, 60,000 wounded and 20,500 missing. Nevertheless, all the 52 reserve German divisions of April 1 had been employed by May 4, and quiet sectors had been robbed to reinforce the Aisne line. Up to May 25, 99 German divisions had already appeared on the front attacked, of which 11 had appeared twice. This expenditure was triple that before Verdun in ten months.

(B. E. P.; C. M. E. M.)

CHAMPAGNE WINES. Champagne is a pale gold or straw-coloured table wine which has been made naturally effervescent through a second fermentation in a bottle or other closed container. It is the best-known of all sparkling wines (*see* WINE), having been developed to perfection through centuries in the former province in France from which it gets its name.

In France, but not normally elsewhere, the name Champagne is restricted to wine obtained from grapes grown in hillside vineyards within a rough triangle connecting Reims, Epernay and Châlons-sur-Marne. White table wines of a number of these vineyards, usually from Pinot noir, Chardonnay and Pinot blanc grape varieties, are blended together to combine their differing characteristics. To the blend are added a special Champagne yeast, and some sugar, either alone or in a syrup with aged wine. In the resulting fermentation carbon dioxide gas seeks to escape; but, blocked by the closed container, it becomes fixed in the wine, to reveal itself in the form of tiny, pungent bubbles, when the bottle is opened for use.

Either of two types of closed containers may be used to encase the fermenting Champagne. In the older, classic method, bottles able to withstand pressures of as much as 100 lb. per sq.in. are employed. Thick corks, held by steel clamps called agraffes, block the necks. The filled bottles are stacked horizontally in tiers and left so for a period of months, until the second fermentation completes itself.

Unwanted sediment is created during the fermentation, and, to remove this, workers place the bottles in racks, necks downward. Each day for months they lift each bottle slightly, twist and partly turn it. The repeated action, called "riddling," shifts the sediment along the glass until it comes to rest on the cork. At this point the bottle's neck is immersed in a freezing solution; the clamp is then released and the gas pressure forces out the cork and a small quantity of frozen wine, containing the sediment. This process is known as "disgorging."

Quickly, before much of the Champagne can be lost, a little sweet liqueur is added, the bottle is strongly corked, the cork is wired on, and, except for final aging, the effervescent wine is ready for use. The amount of liqueur added determines the degree of sweetness of the Champagne. A Champagne may be almost completely dry of sugar ("brut"), semi-dry (usually labelled "extra-dry," "dry" or "sec") or sweet ("doux").

The second, and faster and less expensive, way of producing Champagne is by the "bulk" process. In this, the wine has its second fermentation in large glass-lined tanks which may hold 50 or even 1,000 gallons. From these, after fermentation, the wine is transferred, under pressure, directly into bottles; the sediment is left behind in the tank or removed by a filter.

Outside of France, wines produced in the manner and possessed of the characteristics of Champagne may be sold under that label qualified with the name of the place of origin. When the "bulk" process has been used the governments of some countries, including the U.S., require that fact to be stated. (*See* WINE.)

CHAMPAGNY, JEAN BAPTISTE NOMPERE DE, DUC DE CADORE (1756–1834), French politician, was born at Roanne on Aug. 4, 1756, and entered the navy in 1774. He fought through the war in America and resigned in 1787. Elected deputy by the *noblesse* of Forez to the states-general in 1789, he went over to the third estate on June 21 and collaborated in the work of the Constituent Assembly, especially occupying himself with the reorganization of the navy. He remained in private life from 1791–99, when Napoleon named him member of the council of state. From July 1801 to Aug. 1804 he was ambassador of France at Vienna and directed the incessant negotiations between the two courts. As minister of the interior (1804–7) he proved an administrator of the first order. In Aug. 1807 he succeeded Talleyrand as minister for foreign affairs. He directed the annexation of the Papal states in April 1808, worked to secure the abdication of Charles IV. of Spain in May 1808, negotiated the peace of Vienna (1809) and the marriage of Napoleon. In April 1811 a quarrel with the emperor led to his retirement. In 1814, after the abdication, the empress sent him on a fruitless mission to the emperor of Austria. Then he went over to the Bourbons. During the Hundred Days he again joined Napoleon. This led to his exclusion by Louis XVIII., but in 1819 he recovered his dignity of peer. He died in Paris on July 3, 1834. Three of his sons achieved distinction. François (1804–1882) wrote a history of the Roman empire, in three parts—(1) *Les Césars* (1841–43, 4 vols.); (2) *Les Antonins* (1863, 3 vols.); (3) *Les Césars du III siècle* (1870, 3 vols.). Napoleon (1806–1872) published a *Traité de la police municipale* in 4 vols. (1844–61), and was a deputy in the Corps Législatif from 1852–70. Jérome Paul (1809–86) was also deputy in the Corps Législatif from 1853–70, and was made honorary chamberlain in 1859. He worked on the official publication of the correspondence of Napoleon I.

CHAMPAIGN, a city of Champaign county, Illinois, U.S.A., in a rich agricultural region, 125 mi. S. by W. of Chicago. It is on federal highways 45 and 150; is served by the Big Four, the Illinois Central, the Wabash and the Illinois Traction railways; and has a commercial airport. The population in 1950 was 39,307. Champaign and Urbana, adjoining it on the east, form practically one city, with common public utilities and civic enterprises. The only separate institutions are the post offices and the city governments. Champaign has the greater part of the business and industrial activities, which include railroad repair shops and manufactures of heavy castings, soybean oil and feed, bleachers, gloves, concrete measuring devices, impact registers, caps and gowns. The campus of the University of Illinois (*q.v.*) lies partly in Champaign.

At Rantoul, 14 mi. N., is Chanute field, a flying field of the U.S. army air corps. Champaign was founded in 1855 and incorporated as a city in 1860.

CHAMPAIGNE, PHILIPPE DE (1602–1674), Belgian painter of the French school, was born at Brussels of a poor family. He was a pupil of J. Fouquières; and, going to Paris in 1621, was employed by N. Du Chesne to paint with Nicholas Poussin in the palace of the Luxembourg. His best works are to be found at Vincennes, and in the church of the Carmelites at Paris, where is his celebrated Crucifix, a signal perspective success, on one of the vaultings. After the death of Du Chesne, Philippe became first painter to the Queen of France, and ulti-

mately rector of the Academy of Paris. As his age advanced and his health failed, he retired to Port Royal, where he had a daughter cloistered as a nun, of whom (along with Catherine Agnès Arnauld) he painted a picture highly remarkable for its solid, unaffected truth. This, indeed, is the general character of his work—grave reality, without special elevation or depth of character or charm of warm or stately colour. He produced an immense number of paintings, religious and other subjects as well as portraits, dispersed over various parts of France and now over the galleries of Europe.

Philippe died on Aug. 12, 1674.

CHAMPARAN, a district of India, in the Tirhut division of Bihar, occupying the northwest corner of Bihar, between the two rivers Gandak and Baghmati and the Nepal hills. It has an area of 3,553 sq.mi., and a population (1941) of 2,397,569.

The district is a vast level, except in the north and northwest, where outliers of the Himalayas, known as the Sumeswar and Dun ranges, extend for about 15 mi. into the alluvial plain. The former hills rise to a height of 2,884 ft. at Fort Sumeswar; at their eastern extremity is the Bhikna Thori pass into Nepal. The two ranges, which have an area of about 364 sq.mi., contain stretches of forest and jungle. Elsewhere the land is closely cultivated and teems with an active agricultural population. The principal rivers are the Gandak, navigable all the year round, the Burh Gandak, Lelbagi, Dhanauti and Baghmati. Old beds of rivers intersect Champaran, and one of these forms a chain of lakes which occupies an area of 139 sq.mi. in the centre of the district.

Champaran was the chief seat of indigo planting in Bihar before the decline of that industry. There are a number of salpetre refineries.

The district suffered severely from drought in 1866 and 1874, and again in 1897. As a protection against crop failures the Tribini and Dhaka canals were constructed. The former derives its supply from the Gandak river at Tribini immediately below the Nepal frontier and irrigates a tract in the north of the district. The latter is a minor work taking off from the river Lalbukaya and irrigating several thousand acres in the east. A considerable trade is conducted with Nepal.

Sugauli, a small military station, was the scene of a massacre during the Mutiny; it was there that the Nepalese treaty of 1815 was signed. Three of the sandstone pillars with pillar edicts which Asoka erected to mark the stages of his journey into Nepal are found in this district at the following places: Lauriya Nandangarh, Lauriya Araraj and Rampurisa.

CHAMPEAUX, WILLIAM OF (*c.* 1070–1121), French scholastic, was born at Champeaux near Melun. After studying under Anselm of Laon and Roscelin, he taught in the cathedral school of Paris, where he opposed Roscelin and had Abélard as a pupil.

In 1103 he became a canon of Notre Dame but in 1108 retired to the abbey of St. Victor, where he resumed his lectures. He afterward became bishop of Châlons-sur-Marne, and took part in the dispute concerning investitures as a supporter of Calixtus II. His theological works are the *De Eucharistia* (inserted by Jean Mabillon in his edition of the works of St. Bernard) and the *De Origine Animae* (in E. Martène's *Anecd. nov.*, vol. v, 1717), in which he upholds the theory of creatianism (that a soul is specially created for each human being).

In his *De Generibus et Speciebus* (printed by V. Cousin in *Ouvrages inédits d'Abélard*, 1836), William shows himself an excessive realist by declaring that the universal is the whole reality of the individual, but in his later *Sententiae* (extracts published in G. Lefèvre, *Les variations de G. de Champeaux*, Lille, 1898), he adopts a moderate realism.

For his views and controversies with Abélard *see* ABÉLARD; SCHOLASTICISM.

See Lefèvre, *op. cit.*; Hurtault, "Théologie de G. de Champeaux," in *Rev. de sc. eccl. et sc. cath.* (1908–09); E. Michaud, *G. de Champeaux et les écoles de Paris au XIIe siècle*, 2nd ed. (Paris, 1868); Uberweg, *Grundriss der Gesch. der Phil.*, Teil ii (Berlin, 1928).

CHAMPERICO, a Pacific port of Guatemala, Central America, 28 mi. by the International Railways of Central America from Retalhuleu. Pop. (1950) 982. Exports are chiefly coffee. The harbour is an open roadstead, ships being served by lighter.

CHAMPERTY, in common law, a bargain between a plaintiff or defendant in a cause and another person, to divide the land (*campum partiri*) or other subject matter of the action in the event of success, in consideration of that person carrying on or defending the suit partly or wholly at his own expense. It is a misdemeanour punishable by fine or imprisonment. It differs only from maintenance, in that the recompense for the service which has been given is always part of the matter in action, or some profit growing out of it. Such an agreement is illegal and void.

It is not, however, illegal to charge the subject matter of an action in order to obtain the means of prosecuting or defending it.

CHAMPION, in the judicial combats of the middle ages the substitute for a party to the suit disabled from bearing arms or specially exempt from the duty to do so. Hence the word has come to be applied to any one who "champions," or contends on behalf of, any person or cause.

In the laws of the Lombards (lib. ii, tit. 56, sections 38, 39), those who by reason of youth, age or infirmity could not bear arms were allowed to nominate champions, and the same provision was made in the case of women (lib. i, tit. 3, section 6; tit. 16, section 2). This was practically the rule laid down in all subsequent legislation on the subject.

The clergy, as individuals or corporations, were represented by champions; in the case of bishops and abbots this function was part of the duties of the *advocatus* (*see* ADVOCATE). Du Cange gives instances of mercenary champions who were regarded as "infamous persons," and sometimes, in case of defeat, were condemned to lose hand or foot. Sometimes championships were "serjeanties"; *i.e.*, rendered service to lords, churches or cities in consideration of the grant of certain fiefs or annual money payments.

The office of "king's champion" (*campio regis*) is peculiar to England. His function was to ride, clad in complete armour, on his right the high constable, on his left the earl marshal, into Westminster hall during the coronation banquet and challenge to single combat anyone who should dispute the king's right to reign. The challenge was thrice repeated by the herald, at the entrance to the hall, in the centre and at the foot of the dais. On picking up his gauntlet for the third time, the champion was pledged by the king in a gilt-covered cup, which was then presented to him as his fee by the king. If he had had occasion to fight, and had been victorious, his fee would have been the armour he wore and the horse he rode, the second best in the royal stables; but no such occasion ever arose. This ceremonial was last performed at the coronation of George IV.

The office of king's champion is of great antiquity, but of the actual exercise of the office the earliest record dates from the coronation of Richard II. On this occasion the champion, Sir John Dymoke, appeared at the door of the abbey immediately after the coronation mass, but was peremptorily told to go away and return later; moreover, in his bill presented to the court of claims, he stated that the champion was to ride in the procession before the service, and make his challenge to all the world. This seems to show that the ceremony, as might be expected, was originally performed before the king's coronation, when it would have had some significance. The manor of Scrivelsby is held in grand serjeanty by the service of acting as the king's champion, although the service became obsolete with the coronation banquet.

CHAMPIONNET, JEAN ETIENNE (1762–1800), French general, born at Valence, enlisted in the army at an early age and served in the great siege of Gibraltar. In May 1793 he was charged with the suppression of the disturbances in the Jura, which he quelled without bloodshed. Under Pichegru he took part in the Rhine campaign of that year as a brigade commander and

at Weissenburg and in the Palatinate won the warm commendation of Hoche. He commanded the left wing of the French armies on the Rhine, between Neuwied and Düsseldorf, and took part in the expeditions to the Lahn and the Main. In 1798 Championnet was named commander-in-chief of the "army of Rome," which was protecting the infant Roman republic against the Neapolitan court and the British fleet. The Austrian general Mack had a tenfold superiority in numbers, but Championnet captured Naples itself and there set up the Parthenopean republic. But his intense earnestness and intolerance of opposition soon embroiled him with the civilians, and the general was recalled in disgrace. The following year, however, saw him again in the field as commander-in-chief of the "army of the Alps." The campaign which followed was uniformly unsuccessful, and, worn out by the unequal struggle, Championnet died at Antibes, on Jan. 9, 1800.

See A.R.C. de St. Albin, *Championnet, ou les Campagnes de Hollande, de Rome et de Naples* (1860); M. Faure, *Souvenirs du Général Championnet* (1904).

CHAMPLAIN, SAMUEL DE (1567–1635), French explorer, colonial pioneer and first governor of French Canada, was born at Brouage on the Bay of Biscay. His father was a sea captain, and the boy was early skilled in seamanship and navigation. He entered the army of Henry IV., and served in Brittany. When the army of the League was disbanded he accompanied his uncle, who had charge of the ships in which the Spanish allies were conveyed home, and on reaching Cadiz secured (1599) the command of one of the vessels about to make an expedition to the West Indies. He was gone over two years, visiting all the principal ports and pushing inland from Vera Cruz to the city of Mexico. The ms. account of his adventures, *Bref Discours des Choses plus remarquables que Samuel Champlain de Brouage a recognues aux Indes Occidentales,* is in the library at Dieppe. It was not published in French until 1870, although an English translation was printed by the Hakluyt Society in 1859. It contains a suggestion of a Panama canal, "by which the voyage to the south sea would be shortened by more than 1,500 leagues." In 1603 Champlain made his first voyage to Canada, being sent out by Aymar de Clermont, on whom the king had bestowed a patent. Champlain at once established friendly relations with the Indians and explored the St. Lawrence to the rapids above Montreal. On his return he published *Des sauvages, ou voyage de Samuel Champlain de Brouage fait en la France Nouvelle.* During his absence de Clermont had died, and his privileges and fur trade monopolies were conferred upon Pierre du Guast, Sieur de Monts (1560–*c.* 1630). With him, in 1604, Champlain was engaged in exploring the coast as far south as Cape Cod, in seeking a site for a new settlement, and in making surveys and charts. They first settled on an island near the mouth of the St. Croix river, and then at Port Royal—now Annapolis, Nova Scotia.

Meanwhile the Basques and Bretons got de Monts' patent revoked, and Champlain returned to Europe. When, however, in modified form, the patent was re-granted to his patron, Champlain induced him to abandon Acadia and establish a settlement on the St. Lawrence. Champlain was placed in command of one of the two vessels sent out. He was to explore and colonize, while the other vessel traded, to pay for the expedition. Champlain fixed on the site of Quebec and founded the first white settlement there in July 1608, giving it its present name. In the spring he joined a war party of Algonquins and Hurons, discovered the great lake that bears his name, and, near the present Ticonderoga, took part in the victory which they obtained over the Iroquois. The Iroquois naturally turned first to the Dutch and then to the English for allies. Champlain then returned to France, but in 1611 was back in Canada, and established a trading post at Mont Royal. He was subsequently appointed lieutenant-general in New France.

In 1613 Champlain again crossed the Atlantic and endeavoured to confirm Nicolas de Vignau's alleged discovery of a short route to the ocean by the Ottawa river, a great lake at its source, and another river flowing north therefrom. That year he got as far as Allumette Island in the Ottawa, but two years later, with a "Great War Party" of Indians, he crossed Lake Nipissing and the eastern ends of Lakes Huron and Ontario, and attacked an Onondaga fortified town a few miles south of Lake Oneida. This was the end of his wanderings. He now devoted himself to the growth and strengthening of Quebec. Every year he went to France with this end in view. He was one of the 100 associates of the Company of New France, created by Richelieu to reform abuses and take over all his country's interests in the new world. But in 1629 Quebec was forced to surrender to the English. Champlain was taken to England a prisoner, but when Canada was restored to the French he returned (1633) to his post, where he died. He had married in 1610, Hélène Boullé, then but 12 years old. She did not leave France for Canada, however, until ten years later. After his death she became a nun.

Champlain's works in six vols. were published under the patronage of the University of Laval in 1870. There is a careful trans. of *Champlain's Voyages,* by A. N. and E. G. Bourne (1906) in the "Trailmaker" series ed. by Prof. J. B. McMaster. *See* F. Parkman, *Pioneers of France in the New World* (1865); J. Winsor, *Cartier to Frontenac* (1894); G. Gravier, *Vie de S. Champlain* (1900); N. E. Dionne, *Champlain* (1905); R. Flenly, *S. Champlain* (Toronto, 1924).

CHAMPLAIN, LAKE. This lake is chiefly in the United States, between the States of New York and Vermont, but extends about 6m. into the Province of Quebec, Canada. It is about 125m. long, covers an area of about 600sq.m., varies in width from ¼m. to 12m. and in depth from 100ft. to a maximum of about 400 feet. It drains into the St. Lawrence through the Richelieu river. Lake Champlain receives the waters of Lake George through a small stream containing rapids and falls. It receives the drainage from many other streams, all of them small. The most important ports on the lake are Burlington, Vt., Rouses Point, Plattsburg and Port Henry, New York. Plattsburg Barracks, a beautiful army post, is located on its shores at the city of the same name. It was at this post that the first experiment in training young men for the citizens army was tried out by Gen. Leonard Wood in 1915. The experience here gained was of great value during the World War when speed and efficiency were so essential. Since the World War, many young men of New York and other nearby States have been trained here in the Citizens Military Training Camps and in the Reserve Officers Training Corps.

Lake Champlain is a link in the international water line of communication between the Hudson river and the lower St. Lawrence. The total commerce passing the narrows of the lower end of the lake in 1926 was 115,000 tons. The through traffic consists principally of southbound lumber and pulp-wood and northbound coal. Local traffic is comparatively unimportant. The route from the St. Lawrence south is via the Richelieu river, with the St. Ours lock and dam in its lower course and the Chambly canal in its upper reach. This canal has 9 locks with total lift of 74 feet. The locks have the following dimensions: length, 118ft. (110ft. available); width, 22½ft.; depth on sills, 7ft. (reduced at low water to 6½ft.). The width of the canal is 36ft. at the bottom and 60ft. at the water surface. The "Champlain canal" connects Lake Champlain, at Whitehall, with the Hudson river at Waterford, New York. There are 12 locks with total lockage of 182 feet. The summit level is at elevation 140 and is supplied with water from the headwaters of the Hudson.

With the Green mountains on the east and the Adirondacks on the west, the scenery is rugged and beautiful. Many islands dot the northern portion of the lake. It was discovered in 1609 by the French explorer and soldier Samuel de Champlain, from whom the lake takes its name. During the early period of settlement of the North American continent Lake Champlain was the gateway between French Canada and the English colonies. It played an important part in all the wars in which the people to the north and south of it were on opposite sides. It is rich in the history and traditions of these early days. Champlain, with an expedition of about 80 friendly Montagues Indians, defeated the Iroquois on its shores in 1609. Thus began the long struggle between the French and the Five Nations.

In 1731 the French built a fort at Crown Point and in 1755 another at Ticonderoga; both were important strategic points in the French and Indian War as well as in the American Revolution. They controlled the easiest and most natural route between

Canada and New York. During the Seven Years' War (French and Indian) English and colonial expeditions twice failed to capture Crown Point. It was finally occupied by Amherst in 1759. Early in the American Revolution it was captured by a detachment of Ethan Allen's Green Mountain Boys. Ft. Ticonderoga was the scene of the severe repulse administered to Gen. Abercrombie by Gen. Montcalm in 1758. Later on it was captured by Amherst. At the beginning of the Revolution it was captured in a surprise attack by Capt. Ethan Allen. When asked by the British commander, Capt. La Place, by what authority the surrender of the fort was demanded, Capt. Allen made his historic reply, "In the name of the great Jehovah and the continental congress." During the subsequent years of the war the fort changed hands several times. On Oct. 11, 1776, the first battle between an American and a British fleet, the battle of Valcour island, was fought on the lake. Benedict Arnold, the American commander, with a decidedly inferior force, inflicted severe damage on the enemy and then during the night escaped. Although overtaken two days later he again, after a fight of a few hours, made a successful retreat saving all his men.

At the beginning of the War of 1812 the American naval force on the lake, though very small, was superior to that of the British, but on June 3, 1813, the British captured two American sloops in the narrow channel at the northern end and gained supremacy. Both sides now began to build and equip vessels for a decisive contest. By May, 1814, the Americans had regained supremacy, and four months later a British land force of 11,000 men under Sir George Prevost and a naval force of 16 vessels of about 2,402 tons with 937 men and 92 guns under Capt. George Downie confronted an American land force of 1,500 men under Brigadier General Alexander Macomb, strongly entrenched at Plattsburg, and an American naval force in Plattsburg bay of 14 vessels of about 2,244 tons with 882 men and 86 guns under Commodore Thomas MacDonough (1783–1825). The naval battle occurred on the morning of Sept. 11, 1814. Although the weight of the metal thrown by the guns of MacDonough's American fleet was greater than that of the British fleet, the latter had more guns of long range. Knowing that in a battle in the open lake he would be at a disadvantage, MacDonough anchored his fleet in such a way as to force Downie to pass between him and the land and to prevent him from anchoring his fleet out of range of the American guns. Downie was killed early in the fight, and the British fleet was soon driven out of action or surrendered. The American loss was 52 killed and 58 wounded, and the British loss was 57 killed and 92 wounded. The land forces engaged in desultory fighting but no decisive action occurred. As the lake was entirely in the control of the Americans, Prevost was forced to retreat during the night of Sept. 12–13, leaving his sick and wounded behind. The British gave up further efforts to invade New York.

CHAMPLAIN CANAL: *see* NEW YORK STATE BARGE CANAL SYSTEM.

CHAMPMESLÉ, MARIE (1642–1698), née DESMARES, French actress, was born in Rouen and made her first appearance on the stage at Rouen with Charles Chevillet (1645–1701), who called himself sieur de Champmeslé, and they were married in 1666. By 1669 they were playing in Paris at the Théâtre du Marais. The next year, as Hermione in Racine's *Andromaque*, she had a great success at the Hôtel de Bourgogne. Her intimacy with Racine dates from then. Some of his finest tragedies were written for her, but her repertoire was not confined to them, and many an indifferent play—like Thomas Corpeille's *Ariane* and *Comte d'Essex*—owed its success to "her natural manner of acting and her pathetic rendering of the hapless heroine." *Phèdre* was the climax of her triumphs, and when she and her husband deserted the Hôtel de Bourgogne (*see* BÉJART *ad fin.*), it was selected to open the Comédie Française on Aug. 26, 1680. There, with Mme. Guérin as the leading comedy actress, she played the great tragic love parts for more than 30 years, dying on May 15, 1698. La Fontaine dedicated to her his novel *Belphégor*, and Boileau immortalized her in verse.

Her brother, the actor NICOLAS DESMARES (*c.* 1650–1714), began as a member of a subsidized company at Copenhagen. After 1685 he played peasant parts with great success at the Comédie Française. His daughter, to whom Christian V. and his queen stood sponsors, CHRISTINE ANTOINETTE CHARLOTTE DESMARES (1682–1753), was a fine actress in both tragedy and soubrette parts. She made her début at the Comédie Française in 1699, in La Grange Chancel's *Oreste et Pylade*, and was at once received as *sociétaire*. She retired in 1721.

CHAMPOLLION, JEAN FRANÇOIS (1790–1832), French Egyptologist, called LE JEUNE to distinguish him from Champollion-Figeac (*q.v.*), his elder brother, was born at Figeac, in the department of Lot, on Dec. 23, 1790. At the age of 16 he read before the academy of Grenoble a paper in which he maintained that the Coptic was the ancient language of Egypt. He soon after removed to Paris. In 1809 he was made professor of history in the Lyceum of Grenoble. His first decipherment of hieroglyphics dates from 1821. In 1824 he was sent by Charles X. to visit the Egyptian antiquities in the museums of Italy; and on his return was appointed director of the Egyptian museum at the Louvre. In 1828 he was commissioned to conduct a scientific expedition to Egypt in company with Rosellini. In March 1831 he received the chair of Egyptian antiquities, which had been created specially for him, in the Collège de France. He was engaged with Rosellini in publishing the results of their Egyptian researches when he died at Paris (1832). Champollion is now universally acknowledged to have been the founder of Egyptology.

He wrote *L'Égypte, sous les Pharaons* (2 vols. 8vo. 1814); *Sur l'écriture hiératique* (1821); *Sur l'écriture démotique; Précis du système hiéroglyphique, etc.* (1824); *Panthéon égyptien, ou collection des personnages mythologiques de l'ancienne Égypte* (incomplete); *Monumens de l'Égypte et de la Nubie considérés par rapport à l'histoire, la religion, etc.; Grammaire égyptienne* (1836), and *Dictionnaire égyptienne* (1841), edited by his brother; *Analyse méthodique du texte démotique de Rosette; Aperçu des résultats historiques de la découverte de l'alphabet hiéroglyphique* (1827); *Mémoires sur les signes employés par les Égyptiens dans leurs trois systèmes graphiques à la notation des principales divisions du temps; Lettres écrites d'Égypte et de Nubie* (1833). Champollion also wrote several letters on Egyptian subjects, addressed at different periods to the duc de Blacas and others.

See H. Hartleben, *Champollion, sein Leben und sein Werk*, 2 vol. (1906); *Lettres de Champollion le Jeune* (1909).

CHAMPOLLION-FIGEAC, JACQUES JOSEPH (1778–1867), French archaeologist, elder brother of Jean François Champollion, was born at Figeac in the department of Lot, on Oct. 5, 1778. He became keeper of manuscripts at the Bibliothèque Nationale in Paris, and professor of palaeography at the École des Chartes. In 1849 he became librarian of the palace of Fontainebleau. His works include, *Nouvelles recherches sur les patois ou idiomes vulgaires de la France* (1809), *Annales de Lagides* (1819) and *Chartes latines sur papyrus du VIe siècle de l'ère chrétienne*. His son AIMÉ (1812–1894) became his assistant at the Bibliothèque Nationale, and in addition to a number of historical works wrote a biographical and bibliographical study of his family in *Les Deux Champollion* (Grenoble, 1887).

CHANCE, an accident or event, a phenomenon which has no apparent or discoverable cause; hence an event which has not been expected, a piece of good or bad fortune. From the popular idea that anything of which no assignable cause is known has therefore no cause, chance was regarded as having a substantial objective existence, being itself the source of such uncaused phenomena. For the philosophic theories relating to this subject *see* ACCIDENTALISM.

"Chance," in the theory of probability, is used in two ways. In the stricter or mathematical usage, it is synonymous with probability, *i.e.*, if a particular event may occur in n ways in an aggregate of p events, then the "chance" of the particular event occurring is given by the fraction n/p. In the second usage, the

"chance" is regarded as the ratio of the number of ways which a particular event may occur to the number of ways in which it may not occur; mathematically expressed, this chance is $n/(p-n)$. This is more usually called Odds (*see* PROBABILITY). In the English law relating to gaming and wagering a distinction is drawn between games of chance and games of skill (*see* GAMBLING AND BETTING).

CHANCEL, strictly, that part of a church close to the altar and separated from the nave (*q.v.*) by cancelli or screens. This

LOOKING DOWN OVER THE CHOIR INTO THE CHANCEL OF THE SALAMANCA CATHEDRAL, SPAIN. THE ALTAR IS SEEN IN THE CENTRE BACKGROUND

space, originally known as the space *inter cancellos*, or *locus altaris cancellis septus*, came itself to be called the chancel. Later the word came to include the whole of that part of the church occupied by altars, communion tables and all the officiating clergy and singers, *i.e.*, the presbytery (*q.v.*), the chancel proper and the choir (*q.v.*). In some cases the word is used synonymously with choir.

In basilican churches, the chancel is set apart only by a low railing; *e.g.*, S. Clemente, Rome. Such divisions correspond more to the altar, communion or sanctuary rail of a modern church than to the developed mediaeval chancel screen. In the highly organized mediaeval church, the chancel is clearly differentiated from the nave by the raising of the floor level, and by the chancel or rood screen (*see* JUBÉ). This screen is frequently continued on each side, behind the choir stalls, and around the east end of the cathedrals of sanctuary, as in Paris, Bourges and Amiens. At the side, such screens form the back of the choir stalls. The chancel screen in front of the altar is sometimes only a low parapet, sometimes a light, openwork structure of wood or metal, but often, especially in the large cathedrals and abbeys of England, a massive and solid stone structure, frequently carrying the organ. In collegiate and monastic churches, these screens thus completely separated the spaces reserved for services for the members of the clerical community from the spaces for popular services, for which a second altar was usually set up to the west of the screen, as formerly in Westminster Abbey.

Chancel sizes vary enormously. On the European continent they usually extend from the east end to the crossing, as in many modern churches, but in abbey churches, and generally in English mediaeval churches, they comprise also several bays of the nave. In the churches of Paris the chancel is relatively small. The chancel screen becomes more open and its main function is to support a crucifixion group; it is, therefore, primarily a rood screen. In small churches the chancel is sometimes lower and narrower than the nave.

CHANCELLOR, RICHARD (d. 1556), English seaman, is said to have been brought up by the father of Sir Philip Sidney. Nothing is known of his own family except that he had two sons. In 1553 Sir Hugh Willoughby fitted out an expedition in search of the North-East passage to China, of which Chancellor was appointed pilot general. It was arranged that the expedition should meet at Vardö, but because of unfavourable weather Chancellor's was the only one of the seven ships which arrived. He therefore went on alone into the White sea, and thence overland to Moscow. There the emperor showed him great hospitality and gave him a letter for the king of England giving very favourable conditions for English trade. Chancellor rejoined his ship in the summer of 1554, and went back to England after having, by his successful negotiations, laid the foundations of English trade with Russia. The Muscovy company was established as a result. In 1555 Chancellor left England again for Moscow, which he reached in November. He lost his life in a wreck on the return voyage, on Nov. 10, 1556, off Pitsligo on the coast of Aberdeenshire.

See R. Hakluyt, *Principal Navigations . . . of the English Nation*, 1st ed. (London, 1589)

CHANCELLOR, an official title used by most of the peoples whose civilization has arisen directly or indirectly out of the Roman empire. It stands for very various duties, and is borne by officers of various degrees of dignity. The original chancellors were the *cancellarii* of Roman courts of justice, ushers who sat at the *cancelli* or lattice work screens of a "basilica" or law court, which separated the judge and counsel from the audience (*see* CHANCEL). In the later Eastern empire the *cancellarii* were promoted at first to notarial duties. The barbarian kingdoms which arose on the ruin of the empire in the West copied more or less intelligently the Roman model in all their judicial and financial administration. Under the Frankish kings of the Merovingian dynasty the *cancellarii* were subordinates of the great officer of state called the *referendarius*, the predecessor of the modern chancellor. The office became established under the form *archi-cancellarius*, or chief of the *cancellarii*. Stubbs says that the Carolingian chancellor was the royal notary and the arch-chancellor keeper of the royal seal. His functions would naturally be discharged by a cleric in times when book learning was mainly confined to the clergy. From the reign of Louis the Pious the post was held by a bishop. By an equally natural process he became the chief secretary of the king and of the queen, who also had her chancellor. Such an office would develop on the judicial as well as the administrative side. Appeals and petitions of aggrieved persons would pass through the chancellor's hands, as well as the political correspondence of the king. Great officers and corporations also had occasion to employ an agent to do secretarial, notarial and judicial work for them, and called him by the convenient name of chancellor.

The Chancellor in England.—The model of the Carolingian court was followed by the mediaeval states of Western Europe. In England the office of chancellor dates back to the reign of Edward the Confessor, the first English king to use the Norman practice of sealing instead of signing documents. The chancellor was originally, and long continued to be, an ecclesiastic, who combined the functions of the most dignified of the royal chaplains, the king's secretary in secular matters, and keeper of the royal seal. From the first, then, though at the outset overshadowed by that of the justiciar, the office of chancellor was one of great influence. As chaplain the chancellor was keeper of the king's conscience; as secretary he enjoyed the royal confidence in secular affairs; as keeper of the seal he was necessary to all formal expressions of the royal will. By him and his staff of chaplains the whole secretarial work of the royal household was conducted, the accounts were kept under the justiciar and treasurer, writs were drawn up and sealed, and the royal correspondence was carried on. He was, in fact, as Stubbs put it, a sort of secretary of state for all departments. "This is he," wrote John of Salisbury (d. 1180), "who cancels (*cancellat*) the evil laws of the realm, and makes equitable (*aequa*) the commands of a pious prince," a curious anticipation of the chancellor's later equitable jurisdiction. Under Henry II, indeed, the chancellor was already

employed in judicial work, either in attendance on the king or in provincial visitations; though the peculiar jurisdiction of the chancery was of later growth. By this time, however, the chancellor was "great alike in Curia and Exchequer"; he was *secundus a rege, i.e.*, took precedence immediately after the justiciar, and nothing was done either in the Curia or the exchequer without his consent. So great was his office that William Fitz Stephen, the biographer of Becket, tells us that it was not purchasable (*emenda non est*), a statement which requires modification, since it was in fact more than once sold under Henry I., Stephen, Richard and John (Stubbs, *Const. Hist.* i. pp. 384–497; Gneist, *Const. Hist. of England*, p. 219), an evil precedent which was, however, not long followed.

The judicial duties of the chancellor grew out of the fact that all petitions addressed to the king passed through his hands. The number and variety of these became so great that in 1280, under Edward I., an ordinance was issued directing the chancellor and the justices to deal with the greater number of them; those which involved the use of the great seal being specially referred to the chancellor. The chancellor and justices were to determine which of them were "so great, and of grace, that the chancellor and others would not despatch them without the king," and these the chancellor and other chief ministers were to carry in person to the king (Stubbs ii. 263, and note, and p. 268). At this period the chancellor, though employed in equity, had ministerial functions only; but when, in the reign of Edward III., the chancellor ceased to follow the court his tribunal acquired a more definite character, and petitions for grace and favour began to be addressed primarily to him, instead of being merely examined and passed on by him to the king; and in the 22nd year of this reign matters which were of grace were definitely committed to the chancellor for decision. This is the starting-point of the equitable jurisdiction of the chancellor, whence developed that immense body of rules, supplementing the deficiencies or modifying the harshness of the common law, which is known as Equity (*q.v.*).

The Chancellor in Parliament.—The position of the chancellor as speaker or prolocutor of the House of Lords dates from the time when the ministers of the royal Curia formed *ex officio* a part of the *commune concilium* and parliament. The chancellor originally attended with the other officials, and he continued to attend *ex officio* after they had ceased to do so. If he chanced to be a bishop, he was summoned regularly *qua* bishop; otherwise he attended without summons. When not a peer the chancellor had no place in parliament except as chancellor, and the act of 31 Henry VIII. cap. 10 (1539) laid down that, if not a peer, he had no interest to give any assent or dissent in the House." Yet Sir Robert Bourchier (d. 1349), the first lay chancellor, had protested in 1341 against the first statute of 15 Edward III. (on trial by peers, etc.), on the ground that it had not received his assent and was contrary to the laws of the realm. From the time, however, of William, Lord Cowper (first lord high chancellor of Great Britain in 1705, created Baron Cowper in 1706), all chancellors have been made peers on their elevation to the woolsack. Sometimes the custody of the great seal has been transferred from the chancellor to a special official, the lord keeper of the great seal (*see* LORD KEEPER OF THE GREAT SEAL); this was notably the case under Queen Elizabeth (*cf.* the French *garde des sceaux*, below). Sometimes it is put into commission, being affixed by lords commissioners of the great seal. By the Catholic Emancipation Act of 829 it was enacted that none of these offices could be held by a Roman Catholic (*see* further under LORD HIGH CHANCELLOR). The office of lord chancellor of Ireland and that of chancellor of Scotland (who ceased to be appointed after the Act of Union 1707) followed the same lines.

Chancellor of the Exchequer.—The title of chancellor, without the predicates "high" or "lord," is also applied in Great Britain to a number of other officials and functionaries. Of these the most important is the chancellor of the Exchequer, an office which originated in the separation of the chancery from the Exchequer in the reign of Henry III. (1216–72). His duties consisted originally in the custody and employment of the seal of the Exchequer, in the keeping of a counter-roll to check the roll kept by the treasurer, and in the discharge of certain judicial functions in the exchequer of account. So long as the treasury board was in active working the chancellorship of the Exchequer was an office of small importance, and even during a great part of the 19th century was not necessarily a cabinet office, unless held in conjunction with that of first lord of the Treasury. At the present time the chancellor of the Exchequer is minister of finance, and therefore always of cabinet rank (*see* EXCHEQUER).

Chancellor of the Duchy.—The chancellor of the duchy of Lancaster is the representative of the crown in the management of its lands and the control of its courts in the duchy of Lancaster, the property of which is scattered over several counties. These lands and privileges, though their inheritance has always been vested in the king and his heirs, have always been kept distinct from the hereditary revenues of the sovereign, whose palatine rights as duke of Lancaster were distinct from his rights as king. The Judicature Act of 1873 left only the chancery court of the duchy, but the chancellor can appoint and dismiss the county court judges within the limits of the duchy; he is responsible also for the land revenues of the duchy, which are the private property of the sovereign, and keeps the seal of the duchy. As the judicial and estate work is done by subordinate officials, the office is usually given to a minister whose assistance is necessary to a government, but who for one reason or another cannot undertake the duties of an important department. John Bright described him as the maid-of-all-work of the cabinet.

Ecclesiastical Chancellors.—The chancellor of a diocese is the official who presides over the bishop's court and exercises jurisdiction in his name. This use of the word is comparatively modern, and, though employed in acts of parliament, is not mentioned in the commission, having apparently been adopted on the analogy of the like title in the State. The chancellor was originally the keeper of the archbishop's or bishop's seals; but the office, as now understood, includes two other offices distinguished in the commission by the titles of vicar-general and official principal (*see* ECCLESIASTICAL JURISDICTION). The chancellor of a diocese must be distinguished from the chancellor of a cathedral, whose office is the same as that of the ancient *scholasticus* (*see* CATHEDRAL).

Academic, etc.—The chancellor of an order of knighthood discharges notarial duties and keeps the seal. The chancellor of a university is an official of mediaeval origin. The appointment was originally made by the popes, and the office from the first was one of great dignity and originally of great power. The chancellor was, as he remains, the head of the university; he had the general superintendence of its studies and of its discipline, could make and unmake laws, try and punish offences, appoint to professorial chairs and admit students to the various degrees. In England the chancellorship of the universities is conferred on noblemen or statesmen of distinction, whose principal function is to look after the general interests of the university, especially in its relations with the government. The chancellor is represented in the university by a vice-chancellor, who performs the administrative and judicial functions of the office. In the United States the heads of certain educational establishments have the title of chancellor. In Scotland, the foreman of a jury is called its chancellor. In the United States the chancellors are judges of the chancery courts of the states, *e.g.*, Delaware and New Jersey, where these courts are still maintained as distinct from the courts of common law. In other states, *e.g.*, New York since 1847, the title has been abolished, and there is no federal chancellor.

In diplomacy generally the chancellor of an embassy or legation is an official attached to the suite of an ambassador or minister. He performs the functions of a secretary, archivist, notary and the like, and is at the head of the chancery, or chancellery, of the mission. The functions of this office are the transcribing and registering of official despatches and other documents, and generally the transaction of all the minor business, *e.g.*, marriages, passports and the like, connected with the duties of a diplomatic agent towards his nationals in a foreign country.

France.—The country in which the office of chancellor followed most closely the same lines as in England is France. He

had become a great officer under the Carolingians, and he grew still greater under the Capetian sovereigns. The great chancellor, *summus cancellarius* or *archi-cancellarius*, was a dignitary who had indeed little real power. The post was commonly filled by the archbishop of Reims, or the bishop of Paris. The *cancellarius*, who formed part of the royal court and administration, was officially known as the *sub-cancellarius* in relation to the *summus cancellarius*, but as *proto-cancellarius* in regard to his subordinate *cancellarii*. He was a very great officer, an ecclesiastic who was the chief of the king's chaplains or king's clerks, who administered all ecclesiastical affairs; he had judicial powers, and from the 12th century had the general control of foreign affairs. The chancellor in fact became so great that the Capetian kings, who did not forget the mayor of the palace, grew afraid of him. Few of the early ecclesiastical chancellors failed to come into collision with the king, or parted with him on good terms. Philip Augustus suspended the chancellorship throughout the whole of his reign, and appointed a keeper of the seals (*garde les sceaux*). The office was revived under Louis VIII., but the ecclesiastical chancellorship was finally suppressed in 1227. The kings of the 13th century employed only keepers of the seal. Under the reign of Philip IV. le Bel, lay chancellors were first appointed. From the reign of Charles V. to that of Louis XI. the French *chancelier* was elected by the royal council. In the 16th century he became irremovable, a distinction more honourable than effective, for though the king could not dismiss him from office he could, and on some occasions did, deprive him of the right to exercise his functions, and entrusted them to a keeper of the seal. The *chancelier* from the 13th century downwards was the head of the law, and performed the duties which are now entrusted to the minister of justice. His office was abolished by the Revolution. The smaller *chanceliers* of the provincial *parlements* and royal courts disappeared at the same time. But when Napoleon was organizing the empire he created an arch-chancellor, an office which was imitated rather from the *Erz-Kanzler* of the Holy Roman empire than from the old French *chancelier*. At the Restoration the office of chancellor of France was restored, the chancellor being president of the House of Peers, but it was finally abolished at the revolution of 1848. The administration of the Legion of Honour is presided over by a *grand chancelier*, who is a grand cross of the order, and who advises the head of the state in matters concerning the order. The title of *chancelier* continues also to be used in France for the large class of officials who discharge notarial duties in some public offices, in embassies and consulates. They draw up diplomas and prepare all formal documents, and have charge of the registration and preservation of the archives.

Spain.—In Spain the office of chancellor, *canciller*, was introduced by Alphonso VII. (1126–57), who adopted it from the court of his cousins of the Capetian dynasty of France. The *canciller* did not in Spain go beyond the king's notary. The chancellor of the privy seal, *canciller del sello de la puridad* (literally the secret seal), was the king's secretary, and sealed all papers other than diplomas and charters. The office was abolished in 1496, and its functions were transferred to the royal secretaries. The *cancelario* was the chancellor of a university. *The canciller* succeeded the *maesescuela* or *scholasticus* of a church or monastery. *Canciller mayor de Castilla* is an honorary title of the archbishops of Toledo. The *gran canciller de las Indias*, high chancellor of the Indies, held the seal used for the American dominions of Spain, and presided at the council in the absence of the president. The office disappeared with the loss of Spain's empire in America.

Italy, Germany, etc.—In central and northern Europe, and in Italy, the office had different fortunes. In southern Italy, where Naples and Sicily were feudally organized, the chancellors of the Norman kings, who followed Anglo-Norman precedents very closely, and, at least in Sicily, employed Englishmen, were such officers as were known in the West. The similarity is somewhat concealed by the fact that these sovereigns also adopted names and offices from the imperial court at Constantinople. Their chancellor was officially known as Protonotary and Logothete, and their example was followed by the German princes of the Hohenstaufen family, who acquired the kingdoms of Naples and Sicily. The papal or apostolic chancery is dealt with in the article on the Curia Romana (q.v.).

The title of arch-chancellor (*Erz-Kanzler*) was borne by three great ecclesiastical dignitaries of the Holy Roman empire. The archbishop of Mainz was arch-chancellor for Germany. The archbishop of Cologne held the dignity for Italy, and the archbishop of Trier for Gaul and the kingdom of Arles. The second and third of these dignities became purely formal with the decline of the empire in the 13th century. But the arch-chancellorship of Germany remained to some extent a reality till the empire was finally dissolved in 1806. The office continued to be attached to the archbishopric of Mainz, which was an electorate. Karl von Dalberg, the last holder of the office, and the first prince primate of the Confederation of the Rhine, continued to act in show at least as chancellor of that body, and was after a fashion the predecessor of the *Bundeskanzler*, or chancellor of the North German Confederation. The duties imposed on the imperial chancery by the very complicated constitution of the empire were, however, discharged by a vice-chancellor attached to the court of the emperor. The abbot of Fulda was chancellor to the empress.

The house of Austria in their hereditary dominions, and in those of their possessions which they treated as hereditary, even where the sovereignty was in theory elective, made a large and peculiar use of the title chancellor. The officers so called were of course distinct from the arch-chancellor and vice-chancellor of the empire, although the imperial crown became in practice hereditary in the house of Habsburg. In the family states their administration was, to use a phrase familiar to the French, "polysynodic." As it was when fully developed, and as it remained until the March revolution of 1848, it was conducted through boards presided over by a chancellor. There were three aulic chancellorships for the internal affairs of their dominions, "a united aulic chancellorship for all parts of the empire (*i.e.*, of Austria, not the Holy Roman) not belonging to Hungary or Transylvania, and a separate chancellorship for each of those last-mentioned provinces" (Hartig, *Genesis of the Revolution in Austria*). There were also a house, a court, and a state chancellor for the business of the imperial household and foreign affairs, who were not, however, the presidents of a board. These "aulic" (*i.e.*, court) officers were in fact secretaries of the sovereign, and administrative or political rather than judicial in character, though the boards over which they presided controlled judicial as well as administrative affairs. In the case of such statesmen as Kaunitz and Metternich, who were house, court and state chancellors as well as "united aulic" chancellors, the combination of offices made them in practice prime ministers, or rather lieutenants-general, of the sovereign.

In the modern German empire the *Reichskanzler* was the immediate successor of the *Bundeskanzler*, or chancellor of the North German Confederation (*Bund*). But the *Bundeskanzler*, who bore no sort of resemblance save in name to the *Erz-Kanzler* of the old empire, was in a position not perhaps actually like that of Prince Kaunitz, but capable of becoming much the same thing. When the German empire was established in 1871 Prince Bismarck, who was *Bundeskanzler* and became *Reichskanzler*, took care that his position should be as like as possible to that of Prince Kaunitz or Prince Metternich. The constitution of the German empire is separately dealt with, but it may be pointed out here that the *Reichskanzler* was the federal minister of the empire, the chief of the federal officials, and a great political officer, who directed the foreign affairs, and superintended the internal affairs, of the empire.

In these German states the title of chancellor is also given as in France to government and diplomatic officials who do notarial duties and have charge of archives. The title of chancellor has naturally been widely used in the German and Scandinavian States, and in Russia since the reign of Peter the Great. It has there, as elsewhere, wavered between being a political and a judicial office. Frederick the Great of Prussia created a *Gross-Kanzler* for judicial duties in 1746. But there was in Prussia a state chancellorship on the Austrian model. It was allowed to lapse on the death of Hardenberg in 1822. The Prussian chancellor after his

time was one of the four court ministries (*Hofämter*) of the Prussian monarchy.

CHANCELLORSVILLE, a village of Spottsylvania county, Virginia, U.S.A., situated almost midway between Washington and Richmond. It was the central point of one of the greatest battles of the Civil War, fought on May 2 and 3, 1863, between the Union army of the Potomac under Maj.-gen. Hooker, and the Confederate army of Northern Virginia under Gen. Lee. (*See* AMERICAN CIVIL WAR, and WILDERNESS.) Gen. "Stonewall" Jackson was mortally wounded in this battle.

CHANCE-MEDLEY, an accident of a mixed character, an old term in English law for a form of homicide arising out of a sudden affray or quarrel. This term is not in use in the United States. Manslaughter in one of its various degrees would embrace such a homicide, under U.S. law.

CHANCERY. In English law, the court of the lord chancellor is called the court of chancery. It was consolidated in 1873, along with the other superior courts in the supreme court of judicature. Its origin is noticed in the article CHANCELLOR.

The jurisdiction of the court falls into three clearly marked divisions: a miscellaneous jurisdiction, a common law jurisdiction and, most important, jurisdiction in equity. Of the miscellaneous jurisdiction the most important surviving branches are the jurisdiction in bankruptcy and that in lunacy. Originally, however, the miscellaneous jurisdiction of the chancellor included such diverse matters as the power to punish the misdemeanours of sheriffs and the punishment of those receiving children into an order of friars without the consent of their parents. The common law jurisdiction was never very important: it included the power of holding pleas upon the writ of *scire facias* (*q.v.*) and the jurisdiction possessed by all the superior courts of trying personal actions brought for and against its own officers. Such jurisdiction had largely fallen into desuetude by the end of the 16th century.

The equitable jurisdiction of the court originated in the power which the chancellor assumed in the middle ages of modifying a strict and formal legal system on moral grounds. The distinction between law and the equity which gradually modifies it is one which is common to many legal systems. In England, because the remedies which the common law courts could give were early limited by the forms of writs available, men turned to the chancellor for equity and the two systems came to be administered by wholly independent tribunals whose decisions were frequently in conflict. (*See* EQUITY.) The early jurisdiction of the court of chancery was from its nature extremely vague. As late as the 17th century John Selden said of it: "Equity is a roguish thing. For law we have a measure ..... equity is according to the conscience of him that is Chancellor and as that is larger or narrower so is equity. 'Tis all one as if they should make the standard for the measure a chancellor's foot." In fact, however, by the beginning of the 17th century it is possible to discern certain general principles in the exercise of the court's jurisdiction. Thus, it had begun to give to the *cestui que* trust (*see* TRUST AND TRUSTEES) that protection against the legal owner of his property which enabled landowners to evade the technicalities of the feudal system, and it was using the injunction to restrain the immoral or fraudulent exercise of legal rights. The early 17th century was the principal turning point in the history of the court, for the common lawyers were seeking to prohibit the chancery from interfering with common law rights. James I resolved the conflict between the two jurisdictions in favour of chancery by ordering that "our Chancellor and Keeper of the Great Seal for the time being shall not hereinafter desist to give unto our subjects, upon their several complaints, now or hereafter to be made, such relief in equity (notwithstanding any proceedings at the common law against them) as shall stand with the merit and justice of their cause, and with the former ancient and continued practice and proceeding of our Chancery." From this time onward, although the conflict did not die down until the end of the century, the court gradually developed jurisdiction co-ordinate with that of the common law courts and on settled principles and, in the 18th and 19th centuries, it came to follow precedent as strictly as they. The principal distinction between the two systems was that whereas the rules of common law were supposed to have been established since time immemorial, those of equity could in almost every case be traced to the chancellor who invented them.

In the 19th century the jurisdiction of chancery, now clearly defined, was frequently classified by its relationship to the common law as exclusive, concurrent or auxiliary. Exclusive was its jurisdiction over the forms of property which it recognized, such as trusts and powers, the separate estate of married women and the mortgagor's equity of redemption, and in such matters as the administration of the estates of deceased persons, partnerships and the guardianship of infants. It had concurrent jurisdiction where it gave remedies such as specific performance of contracts and injunctions which the common law did not give. Its jurisdiction was said to be auxiliary where it supplemented the otherwise inadequate machinery of the courts by means of subpoena and discovery. (*See* PRACTICE AND PROCEDURE.)

The existence of two sets of tribunals of co-ordinate jurisdiction had manifest inconveniences and the delays and injustices which resulted from it had, by the early 19th century, become a public scandal. Various attempts, more or less successful, were made to remedy this during the century, and these culminated in the great Judicature act of 1873. Section 24 of this act (repealed and replaced by the Judicature act, 1925, section 37 [1]) enacted that in every civil cause or matter commenced in the high court of justice, law and equity should be administered by the high court of justice and the court of appeal respectively, according to the rules therein contained, which provided for giving effect in all cases to "equitable rights and other matters of equity." The 44th section of the act of 1925 declared the law to be administered in England on certain points, and ordained that "generally in all matters not hereinbefore particularly mentioned in which there is any conflict or variance between the rules of equity and the rules of common law with reference to the same matter, the rules of equity shall prevail." The 56th section specifically assigned certain matters to the chancery division, including those noticed above as having been within the peculiar jurisdiction of the old court of chancery.

The chancery division originally consisted of the lord chancellor as president and the master of the rolls and the vice-chancellors. The master of the rolls was also a member of the new court of appeal, but Sir George Jessel, who held office when the new system came into force, regularly sat as a judge of first instance until 1881, when, by an act of that year (s.2) the master of the rolls became a member of the court of appeal only. By the middle of the 20th century, the chancery division consisted of the lord chancellor and six puisne judges, who were divided into groups of three. To these groups were respectively assigned matters within the peculiar jurisdiction of the division.

In the United States chancery is generally used as a synonym of equity. Chancery courts are equity courts in a few jurisdictions where such courts are separately maintained. For the diplomatic sense of chancery (chancellery) *see* CHANCELLOR and DIPLOMATIC.

(W. P. G.)

CHAN CHAN or GRAN CHIMU, a ruined and deserted pre-Inca city on the coast of Peru, situated some 300 mi. north of Lima and approximately 2 mi. north of Trujillo, in the department of La Libertad. It was once the capital of a populous, powerful and relatively advanced civilization variously known as the Chimu, Yunga or Mochica, whose influence extended from the department of Lambeyeque southward to Ancón, not far from Lima.

The city itself covers a considerable area, and from a careful survey and estimate must have had a population of at least 250,000 at the height of its glory. It consists of a group of separate walled cities, each surrounded by massive walls from 30 to 40 ft. high, from 8 to 12 ft. in thickness at the base and from 1 to 3 ft. at the top; the walls, as well as the houses, so-called palaces, temples and other structures are constructed of adobe bricks, plastered over in most cases with a smooth coat of adobe. No stone and apparently little or no wood entered into the buildings.

Owing to a dry and comparatively rainless climate with no great extremes of temperature the ruins, which under other conditions would surely have disappeared, are in a remarkable state of preservation.

The Chimu.—Whence the population came no one can say. We do know, however, from skeletal remains that are found in great abundance in the burying-grounds about and in the ruins, that they were totally unlike any of the other pre-Columbian peoples of South America, the characteristic that distinguished them being that they were a broad-skulled or brachycephalic race while the Quichuas and Aymaras, Andean tribes who formed the Inca confederation, were respectively a mesaticephalic (or normal) and a dolichocephalic (or long-skulled) people. In this peculiarity the Chimu were more closely allied to the Mayas of the Yucatan peninsula, Southern Mexico, Guatemala and Honduras than any other people of the Western Hemisphere. This lends colour to the theory that they were an off-shoot of the Mayas that broke away from the original stock in remote times and made their way to the coast of Peru where they established and built up the civilization of which we are here treating.

When they settled on these shores is equally hazy. Certain it is that if they drifted here by sea they must have come in comparatively small numbers. On the other hand, if they migrated by land—which seems less probable—they must, at the rate primitive people and people without any fixed objective migrate, have been centuries in building up the civilization of which we find remains to-day, so that it is quite probable that their advent on the coast of Peru may have been about the time of the beginning of the Christian era.

We know their fate somewhat more definitely from legends and accounts related by the Incas upon the arrival of the Spaniards. From these we learn that for a century, more or less, a bitter war was waged between the Inca confederation or Andean tribes and the coastal peoples, the Chimu in the north and the Nazca in the south. Many and fierce are the struggles recorded and the Incas eventually defeated the coastal tribes at their great fortress of Paramonga, near Supe, not far from Huacho on the Peruvian coast north of Lima. This fortress remains to this day and is in a remarkable state of preservation. Having been defeated at Paramonga the Chimu retired behind the walls of their capital, Chan Chan, and were here starved into submission by the besieging Incas. Whether the Chimu were wholly exterminated by their enemies or whether, as was the Inca custom with conquered tribes, they were broken up and distributed in small numbers throughout the empire, we do not know. Certain it is, however, that when the Spaniards came there were no evident remains of the Chimu save their ruined and deserted cities, remains of their irrigation systems and other like traces. This extermination of the coastal peoples has been reckoned to have taken place some 130 or 140 years before the coming of the Spaniards, which would put it in the neighbourhood of the year A.D. 1400.

Remains.—From a study of the ruins we know that Chan Chan was the seat of a great empire whose extent was the entire coast from Lambeyeque on the north to about Ancón on the south. We also know that these were a people who lived mainly by agricultural pursuits. In the vicinity of Chan Chan itself, in the valley of the Chicama, Moche, Viru and other Andean streams, there are evidences of truly remarkable systems of irrigation and certain signs that agriculture was carried on to a considerably greater extent in those ancient times than it is to-day. Fishing also formed an important part of their life and conventionalized figures of fishes and maritime birds form the principal motifs in their mural and other decorations.

That they were highly developed in the arts is likewise patent. They knew the art of mining, smelting and working such metals as gold, silver and copper, though none of the other metals have been found in the ruins. Metal utensils, ornaments and other objects are still found in and about Chan Chan, as are also the remains of an ancient smelter, with considerable quantities of slag. The Chimu were also expert potters; examples of their work are to be found in many museums. Strange to note, there are three known strata of pottery, that in the lowest being of the finest quality, while the top stratum is the poorest, indicating that the art degenerated. From their pottery much of their life and habits may be reconstructed. Wood, as has been noted, appears to play very little part in their arts. This is probably because of the indigenous trees, the willow was too soft and perishable for practical use and the algarroba too hard to be worked. Hence wood was used but little, if at all, except in the making of idols, musical instruments and small objects.

Save for a few small settlements, notably at Huanchaco and at Moche, in the vicinity of Trujillo, where the inhabitants show traces of brachycephalism, the ruined cities, irrigation works, fortresses and the like, as well as all traces of these peoples, have disappeared. (O. Ho.)

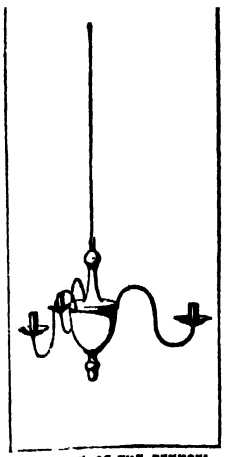
CHANCRE is a term formerly used loosely, to designate any sore or ulcer, especially one of a corroding nature or venereal origin. It is now applied almost exclusively to the primary lesion of syphilis, which used to be called a hard, indurated or Hunterian chancre. It appears at the site of inoculation in from one to seven weeks after exposure, and is most commonly found on the external genitals, but sometimes on the lip, tongue and other parts. A small, hard, translucent swelling appears at the infected spot, becomes gradually larger (up to one inch), and often breaks in the centre leaving a shallow ulcer. This lesion is the chancre and represents the first reaction of body tissues to the causative agent, *Treponema pallidum*. Diagnosis is established by finding the organism in scrapings from the ulcer. (*See* VENEREAL DISEASES.)

CHANDA. The southernmost District of the Central Provinces of British India.

Chanda Town is the old capital of an ancient Gond dynasty, situated near the confluence of the Erai and Wardha rivers. It once had a much larger population for there are now waste and cultivated fields inside the stone walls, which have a circumference of five and a half miles, whilst the modern suburbs of the town have grown up outside the city walls, and in the jungles which hem in the city on two sides there are many traces of old habitations. The town is noted for its silk woven fabrics, ornamental slippers and other minor industries of the same kind. Outside one of the gates is held an annual fair attended by 100,000 people After a great decline from its ancient status as a Gond capital, it has begun to revive with the construction of roads and railway communications, and its population was (1941) 35,730 as compared with 16,000 in 1872.

District of Chanda.—The District of Chanda is one of the largest districts in the Central Provinces, having an area of 9,205 sq.mi., but the twenty Zamindari estates which it contains account for 4,000 sq.mi. of wild and thinly populated country, while government forest reserves cover no less than 2,700 sq.mi., and include valuable teak and other timber, and large bamboo jungles. Coal of a poor quality is found in the extreme west at Ballarpur and Ghugus, while iron ore of high grade is found in the eastern part of the District.

Except in the north-west and on the borders of the Wardha and Nagpur Districts, where cotton and wheat are both grown and there are large areas under juar (sorghum), rice and the small millets are the principal crops. Numbers of irrigation tanks have been constructed by the people to water rice and sugar-cane, to which the Government has added a number of storage reservoirs of some magnitude.



Many useful roads have been made since the great famine and Chanda town is now connected with Wardha on the G.I.P. railway via Warora (where the colliery is now worked out), and by narrow gauge lines with Nagpur and Gondia in the Bhandara district.

It is a most picturesque part of the country, with varied scenery, wooded hills and interesting archaeological remains, old temples and forts, notably at Chanda itself, Bhandak, Markand and Wairagarh, but the climate is unpleasantly hot, the forests malarious, and the people unprogressive. Several languages are spoken.

The Marathi of the north-west gives way to Telugu in the south and to Hindi (Chhattisgarhi) in the north-east. In all the wilder tracts aboriginal races predominate, and Gondi and other

tribal dialects are common, as in the neighbouring Bastar state. The total population of the district in 1941 was 873,284. In the famine decade (1891–1901) there was a sharp decrease, and there was also a setback in population in the decade 1911–21 as a result of an epidemic of influenza.

CHANDAUSI, a town of India in the Moradabad district of Uttar Pradesh; an important junction (for Aligarh) on the Oudh and Rohilkand railway. Pop. (1941) 28,763. It exports cotton, hemp, sugar and stone.

AMERICAN BRASS CHANDELIER 18TH CENTURY

CHAND BARDAI (*c.* A.D. 1200), Hindu poet, a native of Lahore, who lived at the court of Prithiraj, the last Hindu sovereign of Delhi. His *Prithiraj Rasau,* a poem of some 100,000 stanzas, chronicling his master's deeds and the contemporary history of his part of India, is valuable as the earliest monument of the Western Hindi language, and the first of the long series of bardic chronicles for which Rajputana is celebrated. It is written in ballad form, and portions of it are still sung by itinerant bards throughout north-western India and Rajputana.

See J. Tod, *Annals and Antiquities of Rajast'han* (2 vols., 1829–1832).

CHANDELIER, a frame of metal, wood, crystal, glass or china, suspended from the roof or ceiling for the purpose of holding lights. The word is French, but the appliance has lost its original significance of a candle-holder, the chandelier being now chiefly used for gas and electric lighting. Clusters of hanging lights were in use as early as the 14th century, and appear originally to have been almost invariably of wood. They were, however, so speedily ruined by grease that metal was gradually substituted, and fine and comparatively early examples in beaten iron, brass, copper and even silver are still extant. Throughout the 17th century the hanging candle-holder of brass or bronze was common throughout northern Europe, as innumerable pictures and engravings testify. In the great periods of the art of decoration in France many magnificent chandeliers were made by Boulle, and at a later date by Gouthière and Thomire and others among the extraordinarily clever *fondeurs-ciseleurs* of the second half of the 18th century. The chandelier in rock crystal and its imitations had come in at least a hundred years before their day, and continued in favour to the middle of the 19th century, or even somewhat later. It reached at last the most extreme elaboration of banality, with ropes of pendants and hanging faceted drops often called lustres. When many lights were burning in one of these chandeliers an effect of splendour was produced that was not out of place in a ballroom, but the ordinary household varieties were extremely ugly and inartistic. The more purely domestic chandelier usually carries from two to six lights. The present use of electricity and the modern ideas of interior lighting have pushed into the background the elaborate specimens of the past few centuries and substituted the simpler designs with smaller clusters of lights.

ENGLISH CHANDELIER BY ADAMS, ILLUSTRATIVE OF THE MORE ELABORATE MODELS OF THE LATTER PART OF THE 18TH CENTURY

(See also LIGHTING AND ARTIFICIAL ILLUMINATION; INTERIOR DECORATION.)

CHANDERNAGORE or **CHANDARNAGAR,** a former French settlement in India, with a small adjoining territory, situated on the right bank of the river Hugli, 20m. above Calcutta. Area 3 sq.mi.; pop. (1941) 38,284. Chandernagore has played an important part in the European history of Bengal. It became a permanent French settlement in 1688, but did not rise to any importance till the time of Dupleix, during whose administration the town was transformed and became the focus for a considerable maritime trade.

In 1757 Chandernagore was bombarded by an English fleet under Admiral Watson and captured. On peace being established the town was restored to the French in 1763.

When hostilities afterward broke out in 1794, the English again took possession of the town and held it till 1816, when it was a second time given up to the French. Following a plebescite in 1949 Chandernagore was incorporated into India (1950) and became part of Hooghly district, West Bengal (1954).

MODERN ELECTRIC CHANDELIER WITH FROSTED GLOBES AND SILVERED METAL

CHANDLER, RICHARD (1738–1810), British antiquary, was born at Elson in Hampshire. In 1759 he published fragments from the Greek minor poets, with notes (*Elegiaca Graeca*); and in 1763 a fine edition of the Arundelian marbles, *Marmora Oxoniensia,* with a Latin translation, and suggestions for supplying the lacunae. He was sent by the Dilettanti Society with Revett, an architect, and Pars, a painter, to explore the antiquities of Ionia and Greece (1763–66); and the result of their work was the two magnificent folios of Ionian antiquities published in 1769. Other works by Chandler were *Inscriptiones Antiquae pleraeque nondum editae* (1774); *Travels in Asia Minor* (1775); *Travels in Greece* (1776); *History of Ilium* (1803); in which he asserted the accuracy of Homer's geography. His *Life of Bishop Waynflete,* lord high chancellor to Henry VI., appeared in 1811.

A complete edition (with notes by Revett) of the *Travels in Asia Minor and Greece* was published by R. Churton (1825), with an "Account of the Author."
